This relationship can be represented by a parabolic equation. A very similar relationship was found by Coehn (*Zeitschrift für Elektrochemie*, 1907, p. 545) in respect of the formation of sulphur trioxide from sulphur dioxide and oxygen under the influence of ultra-violet light. The relationship between the time of exposure to the light and the concentration of the trioxide can in that case also be represented by curves which are of a parabolic nature.

Prof. Bone's results, which incidentally may also prove to be of technical importance in regard to the formation of nitric oxide by means of gaseous explosions, therefore indicate the possibility of nitric oxide formation by rays of short wave length, which according to the results of Warburg (*Zeitschrift für Elektrochemie*, 1906, p. 538) and others, lead to the formation of appreciable quantities of nitric oxide at ordinary temperatures. Prof. Bone's view that the cause of the different rates of increase in pressure, which he considers to be due to the absorption of energy and to the formation of "activated" nitrogen, may thus be correct. As regards an explanation of the increased formation of nitric oxide, I am, however, of opinion that the assumption of nitrogen activation can be dispensed with and replaced by the known action of ultra-violet rays, which undoubtedly occur when gaseous mixtures are exploded.—I am, Sir, etc.,

Fr. Häusser

Dortmund-Eving, July 12, 1923

THE EFFECT OF INSECTICIDES ON BEES

Sir,—I have read in *Chemistry and Industry* the letter of Mr. W. F. Reid, and another by Mr. W. S. Gilles, commenting upon it and questioning the accuracy of Mr. Reid's impression that bees are killed by spray poison. He dismisses the whole question as merely an extraordinary superstition or prejudice prevalent among bee-keepers. It is, however, such a real fact and constitutes so serious a problem in some sections that much harm would be done should the idea become prevalent that the damage done to bees by spray poisons is only in the imagination of the bee-keeper.

Bee-keeping, of course, is a relatively unimportant industry. Yet it is estimated that the damage suffered by this industry from spray poisoning in the State of Washington last year amounted to $200,000.

In this country a repellant going under the trade name of Milkol has been considered satisfactory by some persons who have tried it, whilst others report unfavourably on it. Milkol is derived from coal tar, but just exactly what it is the writer does not know.

The State College of Washington has carried out a series of experiments on spray poisoning and repellants to be added to sprays to cause bees to avoid them. No doubt interested persons could obtain considerable information by inquiring from that Institution.—I am, Sir, &c.,

D. M. Jackman

Kenvil, New Jersey, July 16, 1923

PHOSPHORUS PENTACHLORIDE AND IODINE TRICHLORIDE AS ELECTROLYTES

Sir,—The letters of Mr. G. W. F. Holroyd in your issue of April 6 (No. 14) and of Prof. T. S. Moore in that of April 27 (No. 17) contain formulæ which indicate that phosphorus pentachloride and iodine trichloride would be electrolytes. Mr. G. W. F. Holroyd hopes to support this opinion by finding a suitable solvent, and Prof. T. S. Moore quotes the works of Oddo and of Walden. In view of the attention which is now given to the electronic theory of valency, I think the following information may be of interest.

Twenty years ago I found the suitable solvent for phosphorus pentabromide, which doubtless would have a formula analogous to phosphorus pentachloride. [*Journ. Russ. Phys. Chem. Soc.*, 35 (1903), 794; *Zeits. Phys. Chem.*, 48 (1907), 220.] Electrolysis of saturated solutions of phosphorus pentabromide in bromine shows that by the electrolysis phosphorus is produced at the cathode, and combines with the solvent, yielding phosphorus pentabromide. (*Journ. Russ. Phys. Chem, Soc.*, 49 (1917), 76.)

Likewise iodine trichloride gives with bromine good conducting solutions (*Ibid.*, 47, 723, 1915). By electrolysis of this solution with the silver anode, silver chloride is obtained at the anode. On electrolysis of a solution of iodine trichloride in dichloracetic acid iodine is liberated at the cathode, giving a violet colour to the solution near the cathode (*loc. cit.*, p. 730).

The results of my investigations fully and clearly show the electrolytic nature of phosphorus pentabromide and of iodine trichloride, in accordance with the formulation used by Messrs. G. W. F. Holroyd and T. S. Moore.—I am, Sir, etc., W. A. Plotnikow

Polytechnicum, Kieff, Russia
July 15, 1923

THE VINEGAR PLANT

Sir,—It was with extreme surprise that I read, at the end of your editorial disquisition on the effect of hydrogen-ion concentration on molluscs, of the proposal to sow "vinegar plants" among lettuces. I fear that the proposal, if carried out, cannot but lead to disappointment, as the cultivation of the vinegar plant requires the environment to be adjusted with a nicety that can hardly be attained under the conditions suggested, for the plant is not a Spermaphyte, but a Cryptogam included in the Bacteriaceæ. As typical species I may mention the *Bacterium aceti*, *B. pasteurianum*, *B. kützengianum* and *B. xylinum*, which have been investigated so exhaustively by Adrian Brown, Hausen and other workers. The common name, vinegar plant, is derived from its ability to oxidise alcohol (by a series of reactions, which, despite the antiquity of the process, are not yet clear) to acetic acid *viâ* aldehyde.

It may be, however, that allusion is made to some plant which is unknown to me. Acetic acid is, of course, a common product in nature, occurring in the juices of many plants, sometimes free, sometimes in combination; for instance, in the seeds of fruit of various species of hogweed, particularly *Heracleum sphondylium* and *H. giganteum*, it is combined with n-hexyl and n-octyl alcohols. Some years ago I detected traces of the free acid in a common weed, but the conditions of the experiment were such as to render a definite conclusion untrustworthy. If there is a new plant which possesses this property to a remarkable degree, I should be glad to receive further information about it.—I am, Sir, etc., "Biochemist"

London
July 28, 1923

PERSONALIA

The honorary degree of LL.D. has been conferred upon Dr. F. W. Aston by the University of Birmingham.

Mr. J. A. Gunton has been appointed professor of chemistry in the Western University, London, Ontario.

Dr. C. A. Browne, chemist-in-charge of the New York Sugar Trade Laboratory, has been appointed Director of the United States Bureau of Chemistry.

Mr. F. W. Horner has been elected chairman and Mr. C. F. Bardorf hon. secretary of the Montreal Section of the Society of Chemical Industry.

The following have been awarded the degree of Ph.D., of the University of London:—L. Hall, H. Phillips, A. Brammall, H. Schofield, and H. F. G. Letson.

It is announced from France that Monsieur Lesage, director of agriculture, Col. Grard of the aeronautical technical service, and Monsieur A. Cagnot have been appointed members of the Permanent Commission of Standardisation.

The following appointments are announced from Germany:—Dr. A. Penrath, to the chair of chemistry in the Technical *Hochschule* in Aachen; Dr. K. Fajans to the professorship of physical chemistry in the University of Munich.

The Gas Light and Coke Co.'s Research Fellowship has been awarded to F. R. Weston, A.R.C.S., for "The Spectroscopic Investigation of the Flames of Carbon Monoxide and Hydrogen, and Matters Cognate thereto," and a Beit Research Fellowship to H. W. Buston, B.Sc., to continue his work on "Nitrogeneous Metabolism in Plants." The research fellowships are tenable at the Imperial College of Science and Technology.

* * *

With regret we announce the death of Dr. P. C. McIlhiney, New York. Dr. McIlhiney, who was a well-known consulting analytical chemist, was for many years honorary secretary of the American Section of the Society of Chemical Industry.

Dr. F. C. Cook, who died in Texas recently, had been connected with the U.S. Bureau of Chemistry since 1904, and was the author of numerous papers on food metabolism, enzymes, insecticides, fungicides and related subjects.

The death is announced of William Brady, chief chemist and chemical engineer to the Illinois Steel Company, Chicago. Mr. Brady had given valuable assistance to the Bureau of Standards in producing standard samples of steel, and was an authority on the exploration and valuation of limestone, fluorspar and other raw materials used in the manufacture of iron and steel.

NEWS AND NOTES

UNITED STATES

Barytes and Barium Products in 1921

The quantity of crude barytes mined and sold in the United States in 1921 fell to about 66,000 short tons as compared with 100,000 t. in the previous year. This decrease is regarded as being only temporary and in large part caused by the post-war depression. The average price per ton obtained in 1921 was nearly 15 per cent. lower than that in 1920, but considerably higher than the prices that prevailed prior to 1919. The value of sales in 1921 was about one-fourth the value of the sales in 1920. The output of crude barytes during 1921 with corresponding values is as follows :—

California ..	Short tons	942	Total value	$5,084
Georgia ..	,,	24,614.	,,	191,442.
Kentucky ..	,,	—	,,	—
Missouri ..	,,	25,200.	,,	217,913.
Tennessee ..	,,	8,180.	,,	61,148.
Other States	,,	7,433.	,,	56,371.

Missouri and Georgia together marketed about 75 per cent. of the total domestic output in 1921. Missouri's production declined about 75 per cent. from that in 1920, but Georgia's output declined only 71 per cent., so that Missouri exceeded Georgia by less than 600 t. Tennessee had the next largest output, which showed a decline of about 72 per cent. In California, which is the only Western State that produced barytes, the production in 1921 decreased 58 per cent. Estimates furnished by the producers of the ore indicate that the total stock held at the end of 1921 amounted to 23,785 short tons. Imports of crude barytes for consumption amounted in 1921 to 11,054 t., and those of crude domestic barytes used in the manufacture of barium products amounted in all to 100,607 t. No barytes was exported, and the amount consumed in the United States in 1921 totalled 77,423 t. The following are statistics of the barium products made from domestic and imported crude ores and marketed in the United States, 1920-1921 :—

	1920 Short tons		1921 Short tons
Ground barytes..	65,748	..	27,661
Lithopone ..	89,373	..	55,016
Barium chemicals	20,760	..	5,487

This makes a total of 175,881 t. for 1920 as against 88,164 t. in 1921, a decline partly due to the large influx of foreign products. Imports of barium products into the United States greatly increased in 1921. They were as follows :—Ground barytes, 1002 t. ; lithopone, 10,493,938 lb. ; barium binoxide, 1,337,972 lb. ; blanc fixe (precipitated barium sulphate), 1,538,383 lb. ; artificial barium carbonate (chemically precipitated), 4,475,225 lb. ; natural barium carbonate (ground witherite), 1,336,712 lb. ; and barium chloride, 12,780 t. (*Cf. J.*, 1922, 131 R.—(*U.S. Geol. Surv., Sept.* 11, 1922.)

Talc and Soapstone in 1921

The total amount of talc and soapstone mined and sold in the United States in 1921 was 126,434 short tons, valued at $1,821,451, which compares with 210,635 t. valued at $3,035,449 in 1920. Vermont was the largest producer ; New York followed in quantity sold, but for the first time took second place in value ; and Virginia ranked next to New York in quantity, but for the first time led in value. There were in all States 30 producers, as compared with 29 in 1920. No soapstone was imported, but the imports of talc, 11,621 short t. valued at $241,748, were reduced, as compared with 1920, to about one-half in both quantity and value. The imports from Canada decreased most, being only 46 per cent. of the quantity imported in 1920 ; the imports from France were less affected, for the French product is of a higher grade. The U.S. Geological Survey estimates the world's production of talc and soapstone in 1920 at approximately 295,000 metric t. The figure for 1921 is not yet available.—(*Cf. J.*, 1922, 482 R.)

FRANCE

The Pasteur Centenary

On July 12, the Syndicat de la Presse and La Bienvenue Française met at the Académie des Sciences to hand over the sum of 8 million francs, collected during "Laboratory Week" to assist scientific laboratories.

The Pascal Centenary

The tri-centenary of Pascal was celebrated in France on July 8, when the President, accompanied by representatives of the "Institut," of the Universities and of foreign scientific societies, visited the summit of the Puy de Dôme, the spot where in 1647 Pascal carried out his famous experiment to demonstrate the pressure of the air. Various speakers, including Messieurs D'Ocagne, Pickard, Painlevé, etc., discussed the scientific work of Pascal and pointed out the practical results of his genial discoveries.

The Nitrogen Industry

The annual report of the Société Central des Industries de l'Air Liquide et de l'Azote, states that the profit during 1922 amounted to 583,000 francs, which has been allocated to depreciation account. It is stated that the preparatory work on the utilisation of the hydrogen of coke-oven gas for the production of synthetic ammonia by means of the Claude process is now completed and negotiations with various firms are in progress to extend this application. A factory is being erected in Spain at Flix (Tarragona), to produce 1000 kg. of ammonia daily, and negotiations are in progress for the erection of other factories in Belgium, Switzerland and Italy, the hydrogen to be produced electrolytically in the two last-named countries, and from coke-oven gas in Belgium.

CANADA

Low Temperature Carbonisation

It is reported that the Ford Motor Company of Canada is erecting a factory for the low-temperature distillation of coal by a process which is expected to produce 10 galls. of motor fuel per ton of coal. The factory, which is situated at Walkerville, Ontario, will cost roughly $500,000, and will distil about 400 tons of coal a day. Should the experimental plant prove successful other factories will be constructed by the company.—(*Chem. and Met. Eng., July* 9, 1923.)

JAPAN

The Alcohol Industry in Formosa

H.M. Consul at Tamsuy reports that the production of alcohol in Formosa during 1922 was 16,353,180 litres compared with 13,072,860 l. in 1921. The production for 1923 is estimated at 19,800,000 l., but it is considered that this output may not be realised. In order to maintain prices the Formosan producers agreed to limit the shipments of alcohol to Japan to 8,000,000 l., but as no restriction is placed on exports to other countries the producers are attempting to increase their exports abroad. Prices for export average 9·50 yen per case of 36 l., the price paid in Japan being 13 yen per case. A tax is applied to alcohol for domestic consumption, but not to alcohol that is exported.—(*Bd. of Trade J., July* 26, 1923.)

GERMANY

Urea as Nutrient Protein

The amides present in plants are not only decomposition products of protein matter, but also intermediate compounds in their synthesis. They are as it were intermediary between inorganic nitrogenous substances and proteins, and, according to C. Lehmann and W. Völtz, may be made under certain circumstances to yield quantitatively true digestible proteins. This is of importance in that such an amide, namely, urea, is at present obtainable from atmospheric nitrogen. Feeding trials conducted with a sheep and three lambs show that urea is a suitable substance for use as nutrient protein.

Wages in the German Chemical Industry, 1923

In the fifteen principal areas of the German chemical industry the average hourly wages of operatives in January, 1923, amounted to 575·95 marks, of process workers to 536·20 m., and of unskilled workers 530·93 m., or, respectively, 1010, 1166, and 1264 times the pre-war figures. The weekly working hours are now six to twelve less than before the war, and the total weekly wages in January amounted to 27,646 m., 25,738 m., 25,435 m. for the three classes of workers, the increases over pre-war rates being 838, 962 and 1047-fold respectively. From the middle of December, 1922, to the middle of January, 1923, the wages of married men increased by 59 per cent., and of single men by 58 per cent. The highest wages are obtained in Cologne, Dusseldorf and Essen.

GENERAL

Copper Ores

A monograph bearing the above title has been prepared by Mr. R. Allen, M.A., under the direction of the Mineral Resources Committee of the Imperial Institute (Pp. 221, price 7s. 6d.). The volume discusses sources of supply within the Empire and in other countries as well as the character, uses, properties and consumption of copper ores. No attempt can be made to give an account of such a detailed production, but it should be indispensable to all those who are interested in the subject.

Discovery of Oil in Spain

El Economista reports that the investigations of a Spanish engineer in the valley of Burunda at Alsásua (Navarre) have confirmed the existence of a hitherto unknown petroleum zone. The geological formation of the zone suggests that the deposit may prove of great importance. The land belongs to the Compañía Franco-Española de Petróleos of San Sebastian, which proposes to undertake boring operations at once.—(*Ch. Comm. J., July* 6, 1923.)

European Coal Production in 1922

Prior to the war the production of coal in Europe totalled 610 million metric tons, of which pre-war Germany produced 31·17 per cent., France 6·56 per cent., and the United Kingdom 47·87 per cent. The present state of production in Europe will be seen from the following table, in which output is given in millions of metric tons :—

	1913 m.t.	Per cent.	1920 m.t.	1921 m.t.	1922 m.t.
Germany (without the Saar)	140·9	23·10	108·4	113·9	119·1
Saar region ..	13·2	2·16	9·8	9·5	11·2
France and Lorraine ..	43·8	7·18	24·3	28·2	31·2
Belgium ..	22·8	3·74	22·4	21·8	21·3
Poland (with E. Upper Silesia)	40·5	6·64	29·4	29·9	36·4
Czechoslovakia.	12·7	2·08	11·1	11·6	—
Great Britain & Ireland ..	292·0	47·87	233·2	166·3	255·9
Rest of Europe	44·1	7·23	—	—	—

Nitrogen Fixation in Denmark

Owing to the shortage of nitrogenous fertilisers in Denmark towards the end of the war, a research committee was appointed to investigate the possibility of establishing the nitrogen-fixation industry in the country. The experimental results obtained were so favourable that it was proposed to establish an experimental factory to produce 260 metric tons of ammonia annually, an amount equivalent to half the annual production of the Danish gas industry. A factory with this capacity would, on the basis of prices ruling in 1920, cost 1 million kroner, and a factory to produce 8000 t. of nitrogen would cost about 10 million kr. The economic feasibility of establishing a nitrogen-fixation works in Denmark is not considered promising at present, especially as German, Chilean and Norwegian competition would have to be met, but the question is being examined by the Ministry of Agriculture.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for July* 26)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received by the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Belgium ..	Tanning extracts ..	103
British India	Cast iron (tender) ..	*
Canada ..	Alum, resin, rubber belting, chemicals, colours	97
Chile ..	Building materials ..	124
Dominican Republic	Steel	673/25 F.G./E.C./2
,,	Cement	8190/F.L./M.C./2
Far East ..	Chemicals, drugs ..	119
Fiume ..	Iron, steel, tinplate ..	105
Hong Kong..	Ammonium sulphate..	11121/F.E./C.C.
Italy.. ..	Hides and skins ..	108
Poland ..	Antimony, copper, tin	112
South Africa	Aluminium paint (tender)	11706/E.D./C.C./2

*Director-General, India Store Department, Branch No. 10, Belvedere Road, S.E. 1.

TARIFF CUSTOMS EXCISE

Dominica.—The export duty on copra has been reduced from 35s. to 20s. per ton.

Federated Malay States.—The exportation of rubber is prohibited except upon licence or coupon authorising such export.

France.—The "coefficient of increase" of 2·5 formerly applied to import duties on crude iodine has now been removed, the duty being fixed at 1600 and 400 francs per 100 kg., under the "general" and "minimum" tariffs, respectively.

Yugoslavia.—The duty-free importation of lead-piping is no longer permitted.

Zanzibar.—Groundnuts and salt may now be imported free of customs duty.

PARLIAMENTARY NEWS

HOUSE OF LORDS

Therapeutics Regulation Bill

A Bill has been introduced by Lord Onslow to regulate the manufacture, sale and importation of therapeutic substances, *i.e.*, vaccines, sera, toxins, antitoxins, antigens, salvarsan and analogous substances, and insulin. The Bill provides that only licensed persons shall manufacture these substances, and licences are required for importation. A Joint Committee consisting of the Minister of Health, the Secretary for Scotland, and the Minister of Home Affairs for Northern Ireland is to be established to frame regulations and to secure uniform standards, and an Advisory Committee is to be appointed, including three Government representatives, and a representative each of the Medical Research Council, the General Medical Council and the Council of the Pharmaceutical Society.

Smoke Abatement Bill

On July 19, Lord Onslow introduced the Smoke Abatement Bill designed to amend the law relating to smoke nuisances. The Bill received the first reading.

HOUSE OF COMMONS

Government Oil Boring

Lieut.-Col. Lane-Fox, replying to Mr. Hannon, said that the amount realised during the year ended March 31, 1923, by the disposal of buildings and plant utilised in the Government oil-boring experiments, was £25,000. The total loss on the undertaking at that date, including interest on Exchequer advances and administrative charges was approximately £678,000.—(July 24.)

Reparation Duty

Answering Mr. F. Gray, Sir W. Joynson-Hicks said that the total amount collected under the German Reparation Recovery Act up to June 30 was £13,264,282. -(July 25.)

Export Price of Indigo

In a written answer to Mr. Collison, Viscount Wolmer said that he was informed that the British Dyestuffs Corporation had not offered to sell any reparation indigo or indigo of their own production for export at prices less than those ruling in this country.—(July 26.)

The Dyestuffs Industry

During the debate on the Board of Trade estimates, Lieut.-Commander Kenworthy raised the question of the Government policy regarding the dyestuffs industry. Dr. G. C. Clayton said that we had all the raw materials of the dye industry, and great progress had been made. He felt sure that with the help of the Board of Trade a dye industry could be established in this country which would hold its own against foreign competition. After showing the necessity for having a sound dye industry in this country, Dr. Clayton pointed out the value of the industry as a school for chemists. Mr. J. H. Simpson observed that the dye merchant played an important part in the organisation of the dyeing industry, and gave instances showing that the merchant objected to be compelled to reveal his customers' names. In reply Sir P. Lloyd Greame said it was necessary that merchants should give these particulars, otherwise the Licensing Committee, which included a majority of users, would not work efficiently. The value of the dye industry to the textile industry in this country was greater now than it had ever been before, as was shown by the present Continental situation. Another important point was that foreign production of textiles was continually increasing and it was unwise to leave our home industry at the mercy of a possible combination of foreign dye-makers and mill-owners. Only when we made dyes in this country did the German prices come down; if the Germans again controlled the market their prices would go up, and there would be no guarantee that they would supply dyes or sell them at reasonable prices.

During further debate on the Board of Trade estimates Mr. H. H. Spencer again raised the question of the administration of the Dyestuffs Act, and complained that the high cost of colours in this country was ruining the important textile industry, the source of roughly 44 per cent. of the manufactured exports of the country. One result was that the small dyers were being crushed out of existence and the cost of dyeing could not be reduced because the dyers were working only at 60 to 70 per cent. of capacity. Sir T. Robinson, speaking as chairman of the Licensing Committee, reviewed the circumstances which led to the passing of the Dyestuffs Act, and claimed that it was not true that the Committee favoured a syndicate or was disadvantageous to the small consumer. The trouble was that France, Belgium and Italy were taking larger quantities of reparation colours than they could consume, and selling the surplus to dealers. Some British consumers were dissatisfied because they could not purchase dyes at prices as low as those quoted in France, Belgium and Italy. The dyestuffs industry had made marvellous progress, but full development would require time. Lieut.-Col. Astbury refuted the statement that the cost of dyes was ruining the dyeing industry, as the cost of dyes represented only 3 per cent. of the whole cost of producing cloth. Cloth that was exported to other countries to be dyed was sent abroad because we could not do the same work in this country, nor could we do it before the war. At present the Germans were charging 8s. 6d. per lb. for colours that we could not manufacture here, but those we could manufacture they were dumping here at any price. —(July 26.)

REVIEWS

Industrial Organic Chemistry. *By* S. P. Sadtler, *Ph.D., LL.D., and* L. J. Matos, *Ph.D. Fifth edition. Pp. xvi*+691. *Philadelphia and London: J. B. Lippincot Co.,* 1923. *Price* 35*s.*

Many technical books are now published. Some are encyclopædic in character; others are small handbooks devoted to individual industries; whilst others attempt to deal compendiously in a single volume with applied chemistry as affecting a variety of industries. Although opinions will differ as to the relative merits and demerits of such books, each of these types doubtless serves a specific purpose. *Industrial Organic Chemistry,* which has now reached its fifth edition, comes under the third category, and any review would be inapposite which failed to appreciate the angle from which the subject had been approached. This work surveys a very wide field of industries, and deals in a systematic way with each industry from the points of view of (*a*) raw materials; (*b*) processes of treatment and/or manufacture, which are outlined and elucidated; (*c*) intermediate and final products, the composition and character of which are furnished; (*d*) analytical and control tests, and (*e*) bibliography and statistics. In the preface to the new edition it is revealed that Dr. Matos is entirely responsible for chapters 9, 10, 13, 14, 15 and 16, covering several industries in which he has had many years' experience, and that Dr. Sadtler is responsible for the rest of the book, which has been thoroughly revised.

Chapter 1 deals, in 45 pages, with the important industry of mineral oil and allied bitumens, and within the space available, the subject has, on the whole, been satisfactorily treated. The account of the processes for treating petroleum, ozokerite, natural paraffin, natural bitumens and asphalts, and bituminous shales impresses one with the scope afforded for the possible improvement in methods of distillation, and the heat economy to be effected in the operation of continuous stills and "topping" plant. No mention is made of the relative advantages of natural and artificial asphalts—a subject of importance in these days.

Chapter 2 is devoted to the industry of fats and fatty oils, both of vegetable and animal origin. Information is given on the extraction of the raw materials and their purification. Both expression and solvent extraction methods are outlined, and brief reference is made to the Cogan, Everard and Wagnet processes of chemical purification of oils used when subsidence and filtration through suitable media have failed to give the necessary purity. In the bibliography at the end of this chapter, no reference is made to the recent work of Prof. J. W. McBain on soap solutions and gels.

Chapter 3 (30 pp.), devoted to the industry of essential oils and resins, surveys briefly the manufacture of perfumes, oils, inks, varnishes, linoleum, and oilcloth, as also rubber and gutta-percha and their products.

Forty-four pages are devoted to the cane sugar industry, which constitutes Chapter 4, and a fairly comprehensive review of the manufacture of sugar from sugar cane and sugar beet is given. The use of multiple-effect evaporators in this manufacture appears to be inadequately treated. No reference is made to the application of artificial refrigeration as a means of facilitating the crystallisation of sugar from its solutions. This is a current development to which attention is being given in this country. Nothing is said concerning the use of new chemical agents for defecation purposes—a phase which has received attention recently.

Chapter 5 deals with starch and its derivative products. In describing suitable converter apparatus for glucose, reference is made to "Maubré," whereas "Manbré" is obviously intended. The fermentation industries are covered by Chapter 6, embodying 80 pages, sectionised as follows :—(*a*) Nature and varieties of fermentation ; (*b*) malt liquors and the industries connected therewith ; (*c*) the manufacture of wine ; (*d*) the manufacture of distilled liquors or ardent spirits, and (*e*) bread-making. In view of the increasing importance of industrial alcohol, one would have imagined that special reference would have been made to this subject, but allusion to this aspect is peculiarly brief, and nothing of an original character is contributed.

Chapter 7 deals with the milk industries (condensed milk, butter, margarine, cheese, etc.) in an interesting way, and Chapters 8, 9, and 10, comprising 96 pages, are assigned to the cellulose industries. Paper-making receives a brief reference in twenty pages, in which the properties and characteristics of various papers are indicated, and the general methods of preparing pulp are given. The cellulose esters and the nitrocellulose plastics are reviewed, and a section is appropriated to the manufacture of artificial silk. In the chapters on vegetable and animal fibres, considerable information appears to have been judiciously compressed. Animal hides and skins, tanning, and glue manufacture are dealt with in Chapter 11, and Chapter 12 deals with the destructive distillation of wood, special reference being made to the fermentation processes in vogue for the manufacture of acetone, which were developed during the war.

Chapter 13 covers the coal-products industries, embracing the manufacture of coal gas and metallurgical coke, and the treatment of the resulting by-products. No allusion is made to generator, regenerative or recuperative methods of heating gas-retort settings, and reference to continuous carbonisation in vertical retorts is very meagre. The information conveyed in this chapter is certainly not up to date, and, indeed, in one or two instances, is inaccurate. For example, on p. 459, in dealing with the distillation of ammoniacal liquor, it is stated that "A pipe leads the ammonia vapours to a lead-lined apparatus termed a saturator, in which is a solution of sulphuric acid, standing at 140° Tw." In point of fact, in working an ammonium-sulphate plant, the specific gravity of the bath is usually about 60° Tw., at 100-110° C. Under tar distillation no reference is made to continuous distillation, either pressure or vacuum, and several of the methods indicated for the production of pure naphthalene and pure anthracene have been found to be ineffective on a practical scale.

Chapters 14, 15 and 16 deal respectively with coal-tar dyes, natural colouring matters, and bleaching, dyeing and textile printing.

Obviously, in attempting to survey 16 important industries in less than 700 pages, it is difficult to decide what to include. There is certainly a demand on the sense of proportion of the authors, and it is inevitable that there should be defects incidental to a necessary compression. Explanations of a chemical and physical character are singularly rare, and hence the book is not calculated to appeal so much to the chemist as to the industrialist, who will appreciate the broad divisions under which the various industries are treated, and will be particularly impressed with the extensive character of the bibliography.

P. PARRISH

DIE FABRIKATION DES ZELLSTOFFES AUS HOLZ SULFITZELLSTOFF. *By* RICHARD DIECKMANN. (*Vol. II. of Technik und Praxis der Papier Fabrikation-*, HEUSER.) *Pp. viii*+360. *Berlin : Otto Elsner*, 1923. *Price* 20*s*.

This exhaustive account of the practice of an important industry makes little appeal to technologists of the United Kingdom, for the simple reason that our production of "sulphite" wood pulp is of fractional dimensions. With our forest area of 4 per cent. as against the 50-60 per cent. of Sweden-Finland, and the 20 per cent. average for Europe, there is moreover no prospect of production from indigenous wood. The North American Continent, on the other hand, has developed a flourishing industry which requires the services of engineer-chemists on a proportionate scale, and this new volume must be commended to them on its obvious merits.

In the historical survey of the industry we notice that the first graph of growth of annual production represents the figures 0–1400 tons in the period 1873-1882. We are therefore in the jubilee year of the industry. This pioneer production is ascribed mainly to C. D. Ekman and his English associates, Geo. Fry, and Thompson, Bonar and Company, a recognition which should be finally adopted.

Following the opening, which tells the story of development to the year 1920, are seven chapters dealing with the subject matter in sections in the order of the succession of operations of the factory routine. This method of treatment results necessarily in a compilation of technical documents, of particular value only to the specialist, whereas the critical didactic method is required for a contribution to technology, which may be or should be a work of general interest. The author is aware of this defect of his contribution and modestly admits its sectional and essentially "practical" purport. Acknowledging the limitation of plan, the author implicitly recognises that the matter has no further cohesion than that which results from consecutive treatment, in order of time, and of successive description of the routine processes and of the machinery and appliances which constitute their factory equipment. These descriptions are exhaustive; the stages of development to present day practice are discussed with critical discrimination, and the work concludes with the design and layout of a modern factory to produce 25 tons a day with prospective increase to 50 tons a day.

These brief notes are intended to call the attention of all specialists engaged in this important industry, especially chemists and engineers, to a work which they will study with deep interest and find indispensable.

In regard to the technology of the subject, it presents another case of an industry very highly developed and very methodically controlled *qua* factory procedure, upon a slender foundation of science: the work faithfully reflects this empirical-technical perfection of the industry. The student who is equipped with a grasp of first principles—of science *and* industry—and, in addition, the critical selective faculty, would find the work attractive for its implicit suggestion of fields of research and enterprise, to be explored before the industry can rank with the ideals of economic realisation. For notwithstanding its ideal basis, a quantitative synthetic reaction of the lignone (non-cellulose) of the wood substance with inorganic compounds of lowest value (costs of production), the resulting by-product represents a waste of material at the present date, and for the fifty years of the industry, of stupendous magnitude.

The history of research, invention and partial realisation of industrial value of this by-product is well set forth in Chapter 7 of the work; and the chemist will read this with the mixed emotions awakened by the story of Palissy and the sacrifice of the household furniture to feed the furnace up to the critical temperature. As for the economic botanist, the spectacle of the wood-pulp industry must raise emotions still more emphatically mixed: on the one aspect the realisation of cellulose qualities in human industry, on the other the wholesale destruction of Nature's values, beyond anything expressed by the mere statistics of tonnage.

The chemical conscience has inspired eloquent lamentations over the world-wastes of glycerin and coal tar: but it has not reached articulate expression in the matter of our complacent sacrifice of wood substance. What is more important, however, is the call for the constructive remedy and for the chemist to undertake it; and the author's work, with the circumstances of its appearance, may be commended to the study of all chemists, and especially to those who have the additional qualifications implied in membership of our Society.

C. F. Cross

Wave Length Tables for Spectrum Analysis. *Compiled by* F. Twyman, *F.Inst.P. Pp. viii*+106. *London: Adam Hilger, Ltd.*, 1923. *Price* 7*s*. 6*d*.

In the preface we are told that "the book consists almost entirely of verbatim transcriptions. For this reason inverted commas have been omitted, all matter other than literal transcriptions or translations being distinguished by italics. The reference to the source from which each extract has been drawn is indicated at the end of each transcription by a reference number, the list of references being given at the end of the volume." From this it follows that the compiler is responsible chiefly for the selections made, but not only so, for the connective text is a useful discussion of the comparative values and correlation of the tables and standards by the principal authorities.

Part I, on "Wave-Lengths and Wave-Numbers," is taken from Prof. A. Fowler's recent work, "Report on Series in Lined Spectra," followed by notes and a table for "Correction to Vacuum of Wave-Lengths in Air" by the compiler. *Part II* traces in detail the history and movements of the International Committee relative to "Wave-Length Standards," and gives a clear exposition of the primary, secondary and tertiary standards. *Part III*, on "Distinctive Lines of the Elements," embodies chiefly the work of Hartley, Pollok, Leonard and A. de Grammont.

It is observed that only certain lines are required for most practical purposes, and their relative significance in ordinary experimental work is indicated. This part also includes a description of the *modus operandi* for the qualitative and quantitative spectroscopic analysis of solutions of salts and minerals by studying their spark spectra as devised by Hartley and Pollok. The compiler has made a valuable re-arrangement of de Grammont's tables by formulating a new table under three columns, the first giving the wave-length in I.A. (International Angström units), the second the symbols of the corresponding elements, and the third the "next sensitive ray" characterising the element. A somewhat similar table of persistent lines by Pollok and Leonard is also given. *Part IV* is transcribed from Dr. J. S. Plunkett's paper, and relates to "Wave-

Lengths for Use in Determination of Stellar Radial Velocities."

The book is essentially a handy work of reference for those practical details required in the course of ordinary practice, and as such, will prove a valuable aid in the laboratory. Its scope is, however, limited to the spark spectra of saline solutions. One may hope that, in course of time, a companion volume on arc spectra will render the work complete.

S. Judd Lewis

The Examination of Hydrocarbon Oils and of Saponifiable Fats and Waxes. *By* Prof. D. Holde. *Authorised translation from the fifth German edition by* Prof. E. Mueller, Ph.D. *Second English edition. Pp. xix+572. London: Chapman and Hall, Ltd.,* 1922. *Price* 30*s.*

The second edition of Holde's *Hydrocarbon Oils and Saponifiable Fats and Waxes,* translated by Mueller, is much more than a mere reissue. The whole book appears to have been largely rewritten and the contents rearranged. The first edition was a translation of the 1913 German edition, whereas the present issue is based upon the fifth German edition published after the end of the war. The new volume contains about 100 more pages, and a great deal more of the detailed analytical and tabular work is in finer print. It is obvious from the references throughout the book that much of the new work up to 1916 published in German has been made use of, but there are evidences that much of the American and British work has not received full consideration, probably because the means were not then available to the author.

As is well known the work is an attempt to bring into one volume a description of the leading methods for the physical and chemical examination of oils, both mineral and vegetable. An astonishing amount of material has been brought together in a work which in many respects is a model for clearness and conciseness.

The opening chapter on the physical and physico-chemical tests contains much new matter. Under the heading of " Heat and Vaporisation " (page 48) the mean boiling point is taken as the arithmetical mean of the boiling point of each 10 per cent. fraction, but work carried out on the lines suggested by Keith and Whatmough (Proceedings of the Institution of Automobile Engineers, 1922) shows that the equilibrium boiling point cannot be so arrived at, being as a rule considerably higher than the figure obtained by the method suggested by Holde.

Due importance is given to the use of formaldehyde as a means for separating certain classes of unsaturated bodies both in naphthas and lubricating oils. This reagent is likely to become more valuable as time goes on, for it is becoming more and more necessary that we should know something as to the constitution both of motor fuels and lubricating oils, particularly in respect of the amount of those ingredients the influence of which Ricardo and others have investigated.

In the chapter on motor oils (page 163) the statement is made that the asphalt content of the oil does not affect its usefulness, for residues of asphaltum oils have been successfully used in Diesel motors. The statement as it stands is hardly correct, and it is qualified further on in the page, the fact being that the hard asphalts are known to be very deleterious, and hence the attention that is being paid to the standardisation of methods for the determination of hard as distinct from soft asphalts. The specifications of fuels for high-speed internal-combustion engines are counsels of perfection.

The difficulties in which Germany was placed during the war owing to the lack of many materials, and not the least lubricating oil, can readily be discerned from a study of this volume. The large amount of space devoted to the influence of graphite in admixture with oil or water as a lubricant is significant. Considerable attention is paid to special oils and technical material concerning various industrial products. Valuable though the chapters on the examination of vegetable products may be, it is the specialised researches of the author on the petroleum products that have made the reputation of the work.

The new volume is a great advance upon the old one, and in spite of many things to which exception might be taken, such as the possibility of producing formulæ to co-ordinate the results obtained by the various technical instruments for measuring viscosity, the book remains one of the most useful in the library of the oil chemist.

W. R. Ormandy

Kelly's Directory of Merchants, Manufacturers and Shippers of the World. *Vol. I. Pp. cccvii+2382. Vol. II. Pp. cxvi+1868. London: Kelly's Directories, Ltd.,* 1923. *Price* 64*s.*

Kelly's Directory of Merchants, Manufacturers and Shippers needs no introduction as it is so well known and has proved its value for many years. As far as can be judged the volumes have been kept well up to date, and alterations made wherever required. Information is given relating to 2000 foreign and colonial towns, so that the work involved has been by no means small. The volume is provided with a brief introduction in four languages describing the arrangement and methods of use. In the present edition the towns and cities of Canada have been arranged in one alphabetical list throughout the Dominions, instead of by provinces. The work conforms to the usual standard of printing and presentation of previous issues, and can be recommended to all those occupied in trade within the Empire or abroad.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business in the home and export markets remains very restricted. Makers' prices are practically unchanged in spite of the unpromising nature of the outlook. The demand from the textile trades is particularly poor, and in general practically no interest is displayed in forward purchasing.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d. - 5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d. - £8 per ton. Comparatively good demand.
Arsenic (White)	£72 - £73 per ton. Not much doing.
Bleaching Powder	Spot £11 7s. 6d. d/d. ; Contract £10 7s. 6d. d/d. Quiet.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£27 per ton.
Potash Caustic	£30 - £33 per ton. Poor demand.
Potass. Bichromate	5¾d.-6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salt Cake	£4 10s. - £5 per ton. Remains a very firm market.
Soda Caustic 76%	£19 - £21 10s. according to quality. Fair business.
Soda Crystals	£5 5s. - £5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	2½d. - 3d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.-£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Rather lower in value but very quiet.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	Cheaper at 10½d. - 1s. 1d. per lb. Ample supplies now available.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

In sympathy with most trades, this market is now a little easier.

Acetate of Lime—	
Brown	£11 5s. - £11 10s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 - £10 15s. per ton d/d, according to locality of market and type of charcoal. Demand easier.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2s. per gall. 24° Tw.
Red Liquor	1s 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. „ „ 60% O.P Firm market as to price but demand quiet.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5-£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d. per lb. spot. 1s. 1½d. per lb. for forward delivery
Crude 60's	3s. - 3s. 6d. per gall. Market firmer for early delivery.
Acid Cresylic—97/99	2s.-2s. 5d. per gall. Steady demand.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 10d. - 2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.

Anthracene Oil—	
Strained	8¾d -11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¼d - d. per gall.
Benzole—	Market uncertain. Prices doubtful.
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d. - 2s. 2d. per gall.
Toluole—90%	1s. 8d.-2s. per gall. Not many inquiries.
Pure	2s.-2s. 4d. per gall. Not much inquiry.
Xylol	2s. 3d. - 3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8½d. - 9d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.-9d. per gall.
Solvent 90/160	1s. 5d. - 1s. 7d. per gall. Quiet.
Solvent 90/190	1s. 4d. - 1s. 7d. per gall. Market quiet.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business passing.
Whizzed or hot pressed	£11 - £13 per ton. More inquiries.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton
Pitch, medium soft	140s.-150s. per ton. Autumn delivery. Market steady.
Pyridine—90/140	18s. per gall. Demand good.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Depression in the textile trade continues, but business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	5s. 3d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Quiet.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.-2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
p-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains exceptionally dull and orders continue to be very scarce.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. per lb. for cwt. lots. Market weak.
Acid, Benzoic	2s. 6d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8d. per lb., less 5%. Demand improved.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.-2s. 3d. per lb. Limited demand.
Acid, Tannic	3s. 1d. per lb. would now be accepted.
Acid, Tartaric	1s. 3d.-1s. 3½d. per lb., less 5%. Demand below normal but improving. Stocks accumulated during the cold spring now being used up and a rise in price not improbable.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very weak.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	20s. 6d. per lb.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source. Market for foreign rather weaker.

Calcium Lactate	2s. 6d. per lb. for best makes.
Chloral Hydrate	3s. 9d. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots. Very dull.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£96 per ton. Quiet.
Guiacol Carbonate	8s. 6d. per lb. Spot supplies short.
Hexamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	70s.-80s. per cwt., according to quality and quantity.
Menthol	40s. per lb. spot.
Methyl Salicylate	2s. 3d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Morphine	Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d. Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb.
Phenacetin	6s. 3d. per lb. Lower in value.
Phenazone	7s. per lb.
Phenolphthalein	6s. 6d. per lb. Firmer.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	94s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d. - 2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 9d. per lb. Very quiet.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s. 3d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots. In better demand.
Sod. Hyposulphite—	
Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 6d. per lb., and Crystal at 2s. 7d. per lb. Market stagnant.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.-1s. 4d. per lb.
Thymol	15s. 6d. per lb. for cwt. lots of natural recryst.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.

TRADE NOTES

Water Treatment

Messrs. Brunner, Mond and Co., Ltd., have issued a pamphlet of 32 pages devoted to water treatment. After considering the impurities present in natural water and the causes and effects of hardness in water, the quantity, measurement and removal of hardness are discussed, the chief methods of water-softening being described in considerable detail. The particular methods advocated in this pamphlet require the use as reagents of soda ash, caustic soda, calcium chloride, silicate of soda, chemicals which are all produced by Messrs. Brunner, Mond and Co. The Company's research department has been specially engaged upon the investigation of the action of natural waters on lead and iron. Special grades of silicate of soda are manufactured with varying proportions of silica and soda to suit the requirements of different types of water, and advice as to the most suitable methods of treatment can be obtained from the Company.

Trade of Canada in 1922—1923

Imports during the fiscal year ended March 31, 1923, were valued at $802,465,043, compared with $747,804,322 in 1921–22. The bulk of these imports were derived from the United States and the United Kingdom, the values supplied being as follows:—Fibres and textile products, United Kingdom, $69,339,824, United States, $77,285,998; wood, wood products and paper, U.K. $270,838, U.S.A. $31,841,957; iron and products of, U.K. $12,671,433, U.S.A. $124,371,885; non-ferrous metals, U.K. $3,595,638, U.S.A. $31,791,237; non-metallic mining products, U.K. $12,508,655, U.S.A. $114,641,860; chemicals and allied products, U.K. $3,636.013, U.S.A. $18,347,545. The value of the exports was $931,451,443, as against $740,240,680 in 1921—1922. Here again trade was mostly with the United Kingdom and the United States, the United States taking by far the larger proportion of the exports of chemicals and related products. The value of the exports of chemicals and allied products was $1,984,441 to the U.K. and $7,951,543 to the U.S.A. The other figures were as follows:—Wood, wood products and paper, U.K. $19,834,368, U.S.A. $191,363,061; iron and its products, U.K. $11,556,627, U.S.A. $9,409,265; non-ferrous metal products, U.K. $8,107,032, U.S.A. $27,889,699; non-metallic mineral products, U.K. $728,674, U.S.A. $20,817,688.—(*Bd. of Trade J., June* 21, 1923.)

Chemical Trade of Finland in 1922

During 1922 the value of the imports into Finland was 3953 million Finnish marks, and of the exports 4461 mill. mk., compared with 3953 mill. mk. and 3389 mill. mk. in 1921. Imports of chemicals and drugs increased in value from 72·33 mill. mk. to 121·16 mill. mk., whilst the value of the export of explosives, matches, etc. increased from 21·52 to 29·17 mill. mk. and of asphalt, tar, rosin, etc. from 10·88 to 11·23 mill. mk.

Imports of Indigo into Shanghai

In 1922 the imports of indigo into Shanghai totalled 211,895 piculs (picul = 132·3 lb.), which originated as follows:—Germany, 156,122 piculs; Switzerland, 37,822 piculs; United States, 12,637 piculs; France, 230 piculs; England, 85 piculs; Japan, 40 piculs; Hongkong, 4939 piculs. As the German agents also represented the Swiss producers, 90 per cent. of the import passed through German hands. The price of indigo fell from 60—90 taels in 1921 to 45 taels in 1922, but rose again in 1923 to 50 taels. Since January, 1923, roughly 1500 piculs of indigo per month has been imported from the United States.—(*Chem. Ind.*, **46**, No. 28.)

Vol. 42 NEW SERIES — LONDON, AUGUST 10, 1923 — No. 32

EDITORIAL

SOME months have passed since Messrs. D. Coster and G. von Hevesy announced in a letter to *Nature* their discovery of a new element of atomic number 72, which they proposed to designate as Hafnium. This announcement at once called forth a protest from Professor Urbain, who pointed out that the element he had discovered in 1911 and named Celtium, had prior claim to the atomic number 72, as had been shown by Dauvillier in 1922. The question promised to be very thorny, as at one time it was uncertain whether two or three elements were in question. But the discussion was soon narrowed down to two elements and the question of the claims of the French and Scandinavian chemists. On March 16, we were able, through the kindness of Professor Biilmann, to publish an article on the subject by Messrs. Coster and Hevesy, who, it seems, lay stress on the following points: (1) the discovery of celtium could not be reconciled with Bohr's theory and (2) the optical spectrum of hafnium obtained by them was entirely different from that described by Urbain for celtium. So far only one side of the case has been stated and we are glad to draw attention to the interesting contribution, beginning on p. 764 of this issue, in which Prof. Urbain reviews the whole question and replies to the evidence adduced by Messrs. Coster and Hevesy. This completes the case, but judgment has still to be delivered. We, therefore, propose to print in our next issue an article in which the evidence is examined dispassionately and an attempt made to indicate the logical conclusion to which it leads.

* * *

The saying that of the making of books there is no end, was never so true as it is to-day. And what a gulf there is between methods old and new! Gone are those spacious days when, as a volume in our possession assures us, Henry Pemberton could issue *A View of Sir Isaac Newton's Philosophy,* dedicating it to Sir Robert Walpole with the warning that "if it were performed suitable to the dignity of the subject, (it) might not be a present unworthy of the acceptance of the greatest person," and hoping that "this attempt, imperfect as it is, to give our countrymen in general some conception of the labours of a person, who shall always be the boast of this nation, may be received with indulgence . . ." in a huge, leather-bound volume of 407 pages, illustrated with choice mythological engravings. What would be thought if some active person were to publish a "view" of the work of a modern scientist, incorporating a poem ("received from a young gentleman") beginning,

> "To X's. genius and immortal fame
> The adventurous muse with trembling pinion soars,"

and following a dedication to the Prime Minister with a list of subscribers, including peers, colonials, clergymen, lawyers and even merchants. Gone, too, are the times when it was possible to say, as did Gibbon of Adam Smith's *Wealth of Nations:* "An extensive science in a single volume and the most profound ideas expressed in the most perspicuous language." These thoughts were called up by Sir Edward Thorpe's most interesting review of *Roscoe and Schorlemmer,* which we print in another column and which awakened many memories, some painful, some pleasant. A new edition of the invaluable Thorpe's *Dictionary* is approaching completion. Richter's *Organic Chemistry* has gone through eleven editions in German alone and, not least, *Roscoe and Schorlemmer* is now in process of rejuvenation. We wondered, thinking of X-ray spectra and of many other modern developments, what kind of library a chemistry student would have in 2023. Nowadays, a single volume can contain but a very small part of any science, so extensive has knowledge become, and to treat a subject adequately implies the preparation and analysis, not to mention the control, of an enormous mass of material. Think of the pages of references in Mellor's Treatise on inorganic and theoretical chemistry alone !

* * *

Another instance of modern complexity is provided by Dr. F. W. Aston's letter to *Nature* of August 4 on the mass-spectrum of copper. After referring to the empirical rules that, without exception so far, none of the elements of odd atomic number consists of more than two isotopes and that, with the exception of nitrogen, the more abundant of the two constituents, or both (except the weaker constituents of lithium and boron), will be of odd atomic weight, Dr. Aston states that he has examined the mass-spectrum of copper and has found faint lines appearing at the expected positions 63 and 65. Professor Dempster recently announced that the above rules would not hold as he found that copper had the three isotopes 62, 64 and 66. Dr. Aston suggests, however, that the lines described by Prof. Dempster agree exactly with those of the strong isotopes of zinc and were possibly due to the presence of traces of that element, either in the copper or more probably in the furnace material.

* * *

This is a time when the professor finishes correcting examination papers and the manufacturer takes no interest in process costs, flow sheets and market reports. Every morning we receive notes expressing the happiness the writer will feel in submitting an article when he comes back from Appin or Kinloch Rannoch, from Llangollen or Tromso. For our part there is a little dale in the North of England, which is more restful than the more expensive and luxurious watering places scattered about the South and East Coasts. One favourite haunt we have in mind, a little smiling corner which above all others cheers us, whose honey is not inferior to that of Hymettus, and whose fruits rival the grapes of Italy. *Cur valle permutem Sabina divitias operosiores?* Why should we exchange our simple dale for the great hotel where we must dress for dinner ? Some we know are already on their way to Bordeaux and the Pillars of Hercules; some have started for Madagascar and the still-vexed Bermoothes ; some favoured by the winds will reach, after a pleasant voyage, Flensburg and Kiel ; others leave for Ostend or Paris : a favourable wind will speed them from the harbour, already the haughty captain calls impatiently, cursing the delay ; hurry up, the ship will wait for no single passenger ! But wherever we go, let us come back refreshed, there is much to be done a month hence. The task calls to us : "Make the most of your holiday, I am waiting for you." Does not the poet in a loftier strain tell us, "Grim death approaches and one of these days, 'Make the most of your life, I am coming,' he says."

SHOULD THE ELEMENT OF THE ATOMIC NUMBER 72 BE CALLED CELTIUM OR HAFNIUM?

By Professor G. URBAIN

It will be useful to summarise briefly the note "On Celtium, a New Element accompanying Lutecium and Scandium in Gadolinite Minerals," which I published in 1911 (*Comptes Rendus*, **152**, p. 141).

After very numerous fractional crystallisations of nitrates of elements of the ytterbium group derived from gadolinite, I separated a few oily drops of last mother-liquors which refused to crystallise. By the well-known methods for separating the rare earths from the other elements, which are indeed only approximate methods, I extracted some centigrammes of a mixture of oxides which, from a study of their arc spectra, was shown to contain a good deal of lutecium, less ytterbium and very little scandium. In addition, I observed a considerable number of new lines which did not appear in any table giving the lines of known elements. I concluded from this and some other observations of less importance that a new and unknown element had been concentrated in the mother-liquors from the fractionation. I gave this the name of Celtium, and supposed that it formed the last term of the series of the rare earths.

My article only mentioned the strongest of the new lines observed ; more than ten years afterwards, however, it became evident that the lines properly belonging to the new element were among the faintest of the lines.

The strongest lines mentioned must be attributed to lutecium. They are spark lines which it had been impossible for me to observe in other samples, however rich in lutecium. I have kept the very small quantity of material which remained after the many experiments made in 1911, and an occasion to make use of this was presented in 1914, when Moseley announced his celebrated law. Thenceforward, the atomic number of every element is determinable by the position of the high frequency lines or X-ray spectra.

I therefore visited Oxford in July, 1914, and Moseley made an X-ray spectrum from my material (G. Urbain, *C.R.*, 1922, 174, p. 1349). This spectrum reveals solely—for the method was at that time not very delicate—the presence of some ten lines at the most, all of which were attributed to lutecium and ytterbium. Without a knowledge of the atomic number, the existence of celtium remained in suspense. I hoped to clear up this question by every possible means, when the war broke out. I was mobilised, which cut short all scientific research, but after the war I communicated with M. de Broglie, who is particularly experienced in X-ray spectra, and explained to him the interest there would be in a repetition of the experiments of Moseley on celtium, making use of a more delicate method. With the aid of such an improvement, where Moseley had been able to see for some element four or five lines of the X-ray spectrum, M. de Broglie was able, in 1922, to observe 30. The examination of substances containing celtium could therefore be attempted afresh, and M. de Broglie asked his collaborator, M. Dauvillier, to make the experiment. M. Dauvillier obtained a very extended exact spectrum in which he observed two new lines attributable to the element 72. On this subject he wrote (Dauvillier, *C.R.*, 1922, **174**, p. 1347), ... "two extremely faint lines demonstrate the existence of celtium and assign to it the atomic number 72. These lines are $\beta_2 = 1319{\cdot}4$ and $\alpha_1 = 1561{\cdot}8$."

He showed that these two lines could neither be attributed to erbium nor to holmium, the presence of which would have added to the confusion. These two elements were entirely absent, since their principal lines could not be detected.

A comparison of my article of 1911 with that of M. Dauvillier shows the corrections which the latter affords; on the main point, that is to say, the existence of a new element, we agree. M. Dauvillier is quite positive on this point. He assigns the number 72 to this element and calls it celtium.

Nevertheless, M. Dauvillier only distinguished a trace of celtium in a substance where I had originally supposed much to be present. It, therefore, became probable that the strong new lines which I had mentioned in 1911 did not belong to the new element, but to some other element which accompanied it (G. Urbain, *C.R.*, **176**, p. 469). Experiments subsequently made in my laboratory have now convinced us that these lines belong to the spark spectrum of lutecium (J. Bardet, *C.R.*, **176**, p. 1711).

We can draw from these preceding observations certain conclusions which will be helpful in the latter part of this memoir.

1. My material did indeed contain, as I have stated, a new element; its X-ray spectrum showed that this was the element whose atomic number is 72.

2. M. Dauvillier and I agreed in calling this element Celtium, because we were certain that it was the same new element which had been detected by me in 1911.

3. The lines which I had mentioned in 1911 did not belong to celtium but to lutecium.

The mistake in interpreting my work of 1911 was corrected by these observations of 1922 (Dauvillier, *loc. cit.*; G. Urbain, *C.R.*, **174**, p. 1349). In effect, to define an element it is sufficient, in the present state of our knowledge, to know its atomic number. The X-ray lines of No. 72 having been observed and this element having been called celtium by those who discovered it, it is inadmissible that the number 72 should be now called by another name, unless some priority is duly established.

I think I should insist on the point that it is logically absolutely futile to complain about what was written in 1911, since the results of 1922 provided a definite answer to the question.

But now, Messrs. Coster and von Hevesy in 1923 (*Nature*, January 20, 1923) observe in zirconium minerals the same X-ray spectrum of the element 72, that is to say, the spectrum of celtium, already observed by us in 1922 in a different material. They were led to choose zirconium by the theoretical ideas of Prof. Bohr, who, from *a priori* reasoning, considered the element 72 should be a satellite of zirconium. Is that a sufficient reason for changing the name of the element 72, which had already been called celtium ?

It is not of great importance in the discovery of a new element whether one finds it associated with the rare earths or with zirconium. There is no law which compels the elements to associate themselves strictly in accordance with their classification, however excellent this may be, and chemistry presents far too many cases to the contrary to justify such an argument.

Besides, the merit of bringing together celtium No. 72 with zirconium belongs either to Mr. Bury (*Journal of the Chemical Society*, 1921) or to Prof. Perrin, who after consulting me made this suggestion and indicated this in 1921 in the last edition of his book, "Les Atomes," 1921 (1921, *Liste des Elements*, p. 512), that is to say two years before Messrs. Coster and von Hevesy dealt with the matter.

So it seems the idea which guided the Danish men of science was not new, and, on the other hand, the spectrum which they have obtained does not differ from that obtained by M. Dauvillier, so that their argument is not justified in any way.

The question is, do the lines in the X-ray spectrum observed in my material belong to the element No. 72, or do they not ? This is the whole question, and it only leads to confusion if one gets away from it. Let us see then what Messrs. Coster and von Hevesy have said on this essential point.

Messrs. Coster and von Hevesy (*Nature*, January 20, 1923): "The only lines which Dauvillier claims to have detected are the lines $L\alpha_1$ and $L\beta_2$, both of which he finds to be extremely faint. The wave-lengths he gives, however, for these lines are about 4 X-units ($X.u = 10^{-11}$cm.) smaller than those which are obtained by a rational interpolation in the wave-lengths of Hjalmar and Coster, for the elements in the neighbourhood of 72."

Messrs. G. Urbain and A. Dauvillier (*Nature*, February 17, 1923): "On their side, Messrs. Coster and Hevesy have observed in certain zirconium compounds of Norwegian origin six high frequency lines characteristic of the element 72. This result was immediately tested by one of us with a sample of zirconium. The lines attributed to element 72 coincide exactly with those found in the ytterbium minerals, with this sole difference that the proportion of element 72 contained in them is notably larger." And in the note, "A photograph of the spectrum obtained with another fraction of ytterbium mineral with an improvement of the experimental conditions (the oxides strongly compressed and calcined in vacuo, in a linear anticathode furnace) has already furnished us with a clearer and more intense line measurable with greater precision. We have thus found: $\beta_2 = 1322{\cdot}8$ and $\alpha_1 = 1564{\cdot}1$ X. u., figures which coincide with the values obtained by interpolation."

It follows from this that the argument put forward by Messrs. Coster and von Hevesy cannot concern anything except the accuracy of the measurements, which is of no consequence in the question of the existence of the lines which alone is of interest in the question of priority.

The accuracy of the measurement is really of secondary importance. It is sufficient to observe one line of the X-ray spectrum in a given spectral area to identify an element, unless some other element has lines in this particular area. What have Messrs. Coster and Hevesy replied to this? We read in *Nature* of February 24, 1923, p. 252, one phrase which proves that they avoid our reply. They say in effect: "Our main reasons for believing that the element celtium, the detection of which was announced by Urbain in 1911, is altogether different from the element detected by us and named hafnium, are . . ."

Messrs. Coster and Hevesy obviously forget that they named the element 72 hafnium because they had observed later than we did the lines of its high frequency spectrum. But in our note which appeared in *Nature* of February 17, and which Messrs. Coster and Hevesy were acquainted with (because they say in their second letter that the Editor of *Nature* had had the courtesy to communicate our reply to them before publishing it), we said:—

"2. The examination of the high frequency spectrum of compounds containing celtium had the definite aim of finding out if this element could be identified with element 72. It would have been very remarkable after having observed this high frequency spectrum not to have attributed it to celtium. But even if the arc-spectrum and the high frequency spectrum in question could not be attributed to the same element (as we have logically admitted), it remains none the less true that we were the first to discover the element 72. In consequence Messrs. Coster and Hevesy have not the right to give it a new name themselves. But Messrs. Coster and Hevesy leave one to understand that the high frequency lines observed by Dauvillier do not exist on our photographs, or that he has been mistaken as to their origin. They say, in fact, in the same note:—'Quite apart from the possibility of accounting for these lines as due to a higher order spectrum of other elements, it seems to be very unlikely that these lines should be due to a contamination of Urbain's preparation by a trace of hafnium.'" (*Nature*, January 20, p. 79.)

It seems to be necessary to indicate precisely the nature of the elements whose X-rays lines of a superior order could be confused with those which we have attributed to element 72. It is strange that these gentlemen keep less to the question of fact than to the probabilities which they deduce from their theoretical opinions, but what is even more surprising is that they systematically neglect our very clear reply on the exact coincidence of the lines of 72 observed in my celtium samples, and those finally observed by us in a celtium-bearing zirconium. They say a little later on:—

"They do not coincide within the limit of experimental error with our measurements of the hafnium X-ray lines $L\alpha_1$, and $L\beta_2$, but also the reason given by Dauvillier for not detecting the line $L\beta_1$, which is stronger than $L\beta_2$, can scarcely be maintained. In fact, our measurements for this line give a value which differs about 3 X-units from the Lu-line denoted by Dauvillier as $L\beta_2$, and with the dispersion used it should be easily separated from the latter line."

Can Messrs. Coster and Von Hevesy believe that an experimenter can be found who does not prefer to identify his lines by a method of coincidences (which does not admit of error), rather than by a method of measuring which necessarily admits of errors? If, on the other hand, Messrs. Coster and Hevesy do not take into account the definite replies which we have made to their criticisms, to whom are they addressing their remarks? We cannot leave without any reply the criticisms of those who have disagreed with us.

In his letter on "The high frequency spectrum of celtium," Dauvillier (*C.R.*, 176, p. 676) says: "In a new letter to *Nature* (February 24, 1923), Messrs. Coster and Hevesy question our having attributed to celtium the lines 1319·4 and 1561·8 X-units which we have observed in a preparation of oxides of ytterbium of M. Urbain. They base their argument on the three following statements:—

1. These lines do not coincide, within the limits of experimental error, with the theoretical interpolation values and the wave-lengths observed in zirconiferous ores.
2. They might come from spectra of superior orders from other elements.
3. We have not observed line β_1, which ought to be visible on our photograph.

We are therefore obliged in this letter to explain in detail the reasons which justify the conclusions which we drew.

(1) There is an effective disagreement of about 3 X-units (10^{-11} cm.) between the wave-lengths published by us and their most

probable values for the lines β_2 and α_1 of celtium, but this difference is by no means outside the limits of possible error. These limits vary in effect a good deal in accordance with the intensity, the nature and the positions of the lines. Our dispersion corresponded with 7 X-units per millimetre. Normally-placed lines with distinct margins can in these conditions be measured by their centres to an accuracy of about 0·1 millimetre, but very feeble lines like those which are here in question can only be measured to an accuracy of about two-tenths or three-tenths of a millimetre.

With the point light source (1·2 mm.) and the wide slit (0·4 mm.) which we then used, these very fine lines appear always diffuse. They cannot be distinguished when viewed too closely and can only be read when viewed from a certain distance. They are besides a little irregular (which makes their definition difficult), by reason of the defects of structure of the salt crystals and an alteration of the reflecting surface which is difficult to avoid. The lines in question are nevertheless beyond doubt, and we have measured many such (γ_9, γ_{10}, γ_{11}, β_7, and β_5 in the group of the rare earths, β_{11}, etc.) which can be classed in the series and are capable of theoretical interpretation. We have besides improved our experimental method. . . . In these conditions the lines have appeared less diffused and have permitted of better definition. We have thus found $\beta_2=1323$ and $\alpha_1=1564$ X-units, figures which coincide with the probable values. The photographs obtained by both methods show no difference appreciable to the eye in the position of the lines when one compares them directly with a more intense spectrum of celtium obtained from the zirconiferous preparation.

(2) Can the lines in question belong to a spectrum of a high order of some other element ?

(*a*) Line β_2. This line cannot belong either to the first or second order of the K spectrum of any element known or unknown. It cannot be a third order of the feeble line K of indium, according to an ancient measurement by Friman, because the limit of K absorption measured by Duane indicates for this line, in accordance with other considerations, the value of 445 X. Another line of the fourth order is not compatible with the tension made use of. In the L series this line cannot be β_1 of tantalum, nor γ_7 of erbium, for the strong lines γ_1 and α_1 of the first of these elements, and β_1 and β_2 of the second element are absent, in accordance with the results obtained from special study of the arc spectrum of these elements. This line cannot belong to a second order of the L series of another element.

(*b*) Line α_1. No line of the K series of the first order shows this wave-length. It is not a line Kα_1 of zirconium of the second order, for this element has been vainly sought for in its first order spectrum with an exposure which should have made its lines two or three times more intense than is the line in question. The arc spectrum has confirmed its absence. It cannot be the line Kβ of palladium in the third order because the line Kα_1 is not visible in the second order. Finally, it is not the line Kα_0 of barium in the fourth order because the lines in this element have not been observed in the third. In the L series this line coincides only with β_2 of holmium, of which the line β_1 should be notably stronger. Only a very doubtful trace appeared in this position on a photograph from another preparation rich in thulium in which no ray of erbium was visible. The ray in question is certainly not β_2 of holmium. The possibility of an L line in the second order is excluded.

(3) The line β_1 β_6 of celtium is not plainly visible on the first of our photographs, although it differs by three X-units from the satellite of β_2 of lutecium, but one must remark that it ought to have appeared between a very strong and persistent line β_2 of lutecium $=1366·7$ and a sufficiently intense, wide and diffuse line Kγ of copper$=1377·7$ in a spectral region of a theoretical width of 11 X-units. But it is impossible to distinguish a fine line under these conditions, and this is proved by the fact that β_6 of lutecium, which ought also to be placed in the centre of an interval existing between two strong persistent lines β_2 Yb$=1412·4$ and β_1 Lu$=1420·5$ ($\Delta=8x$) is absolutely invisible, although it was previously much more intense, *i.e.*, when viewed alone. On the other hand, in a photograph obtained with a linear source, avoiding the presence of the lines of copper and dealing with a preparation not so rich in lutecium, we have observed one more fine line measuring 1378 X-units and having the same intensity as β_5 of ytterbium. This line is neither γ_4 of dysprosium nor any other L line of the second order. It does not correspond with any possible K line of the first order. It is neither Kγ of zirconium of the second order nor Kα of tellurium of the third order, nor Kβ of barium in the fourth order."

To this closely-reasoned and rigorous argument, what have Messrs. Coster and Hevesy replied ? Nothing, at least so far as our knowledge goes. The question of fact is therefore as follows :—

(1) The X-ray lines observed by Dauvillier are without dispute characteristic of element 72.

(2) Messrs. Coster and Hevesy cannot have discovered it, and have no right to give it a new name. In fact, it is reserved to those who have first observed the characters of the element hitherto unknown to give it a name, and from the time that element 72 received the name of celtium, it is this name that ought to be preferred.

All that remains of the arguments of Messrs. Coster and von Hevesy are their purely theoretical considerations. I have already stated that no purely theoretical reasoning ought to prevail against a well-established question of fact, and the fact is the following :—

The sample of material rich in lutecium, which is the subject of this dispute, contains, notwithstanding any doubt cast upon it by Messrs. Coster and von Hevesy, a trace of a new element, foreseen and designated by Moseley under the atomic number 72 and named celtium by Dauvillier and me. In the theoretical considerations of Messrs. Coster and von Hevesy, one must separate those which are well founded and those which are exaggerated. Celtium is, it appears, a homologue of zirconium. On this point Bohr has some ideas, the value of which I contest less because I had accepted the similar opinion of Perrin long before I knew the ideas of Bohr on this subject. I accepted this opinion without the least difficulty because there is no sort of objection—not even Bohr's theory of atomic constitution—to the fact that elements with distinct valencies accompany each other in various chemical reactions. Do we not know that thorium, which is tetravalent, is always accompanied by [the rare earths ? It would be futile to make a list of the elements with distinct valencies which are very difficult to separate chemically and which cling so closely together that one cannot separate them in a state of spectroscopic purity except by very laborious treatment.

Messrs. Coster and von Hevesy cannot be ignorant of such well-known facts. Besides, Bohr's theory is only concerned with facts which have some relation to the atom, and chemical phenomena hardly come under this category, unless the elements are taking part in the reactions as simple ions. It is altogether improbable that zirconium can in aqueous solution act as a simple ion Zr^{++++}. On the other hand, it is highly probable that, in aqueous solution, zirconium is always present in some complex ion. It remains to be seen whether Bohr's theory enables one to foretell how complex ions can behave chemically. It is not less certain that there exists a very large number of cases of isomorphism, which escape the law of Mitscherlich, and which one cannot interpret without the supposition of complex isomorphous groups, as, for instance, in the fluorides of titanium (valency 4) and the oxyfluorides of niobium (valency 5).

Besides these facts, there exist others which relate to the phenomena of adsorption by precipitates. I have found celtium in rare earths which had been submitted to numerous precipitations and previous crystallisations, and I naturally supposed that I was dealing with a rare earth, the doctrine of Bohr being at that time unknown.

In conclusion, I may recall a little piece of history. Crookes, who discovered thallium in mixtures of selenium and tellurium, which certainly did not contain more of it than my ytterbium earths contained celtium, took thallium as a homologue of selenium. I do not suppose that there was any chemist who, under the same conditions, would not have made the same mistake. After some time, Lamy rediscovered thallium, and as he recognised that in its metallic state it resembled lead and as an ion resembled potassium, he tried to do to Crookes what Messrs. Coster and Hevesy are trying to do now with Monsieur Dauvillier and myself. He claimed that thallium did not belong to the same group as tellurium, that the reactions cited by Crookes were illusory, that his green line emanated from an impurity in his material, and that in consequence the true discoverer of thallium was Lamy. Nevertheless those who were competent to judge did not agree and thallium is now universally credited to Crookes, though this does not imply that the work of Lamy was not work of the very first order.

CHEMISTRY IN THE ELECTRICAL INDUSTRY

By ALAN A. DRUMMOND, M.Sc.

The value of the chemist's work in the electrical industry is not always recognised, particularly when the branch concerned is that of the manufacture of electrical machinery as distinct from electrochemical manufactures. The construction of electrical machinery, however, involves the use of a wide variety of materials, and a knowledge of the chemical properties of such materials and their behaviour under varying chemical and physical conditions is of great importance in the control of manufacture and in ensuring uniform and standard results from the manufactured products.

The uses, for instance, of metallurgical chemistry are apparent in providing suitable specifications for the metals to be used in the construction of electric motors, transformers and the like, and in studying the causes of faults and breakdowns. Again, chemistry both organic and inorganic is involved in the manufacture of electrical insulating materials, as these are made from a great range of different substances. The more the specific properties of these substances are known and appreciated, the greater the efficiency of the insulators manufactured and the greater the economy that can be effected in the manufacture. Such knowledge and appreciation can be satisfactorily supplied by the chemist.

Insulating varnishes offer great possibilities of variation in quality and behaviour, and unless carefully checked and tested in the laboratory, are likely to cause a great deal of trouble, expense and annoyance, especially if each new batch requires some alteration in the factory routine in order to give satisfactory results. A pre-determination in the laboratory of the behaviour to be expected will obviously allow of economy of time and materials. Experiments on the factory scale that interrupt the usual factory routine are to be avoided wherever possible.

In respect of insulating varnishes alone a brief consideration of the properties which require to be investigated and tested in the laboratory will reveal the large field for the work of the chemist in the electrical industry. Thus, for example, the properties of viscosity and density are important in their influence on the penetrating power of the varnish. It will be realised that varnishes of equal insulating properties will show the superiority of one over another by the value of the penetrating power. Again, with dried varnishes tests are required of flexibility and durability during use not only under ordinary conditions, but at high temperatures and in moist atmospheres. Heat insulation and resistance to the action of chemicals (acids, alkalis and solvents such as petrol, benzol and oils) must be tested. A vital factor is the time required for drying. Insulating varnishes which possess good air-drying properties are extremely valuable. The majority of these varnishes require stoving and this treatment requires laboratory control, as too little stoving will tend to give sticky films and over-stoving may detract from the flexibility and wearing properties of the varnish.

Although the determination of the dielectric strength, the breakdown voltage and the electrical resistance is strictly a matter for the electrical engineer, the chemist is able to appreciate the significance of the figures obtained and is able to correlate them with the values obtained in determining the chemical properties. In this way it is possible to specify the most closely suitable material for the particular object in view.

Softening point and inflammability are two remaining tests that must be applied to these varnishes.

The variety of properties requiring study in insulating varnishes may be better realised on considering the different groups into which such varnishes can be divided. Fleming and Johnson (" Insulation and Design of Electrical Windings," Longmans, Green and Co.) make the following classification according to the applications :—(A) For impregnating windings; (B) for treating papers and fabrics; (C) for cementing purposes; (D) finishing varnishes. Division can also be made according to properties into: (*a*) oxidising, and (*b*) non-oxidising, and again into (1) air-drying and (2) stoving. It is easily realised that varnishes of class (A) and class (B) must be capable of withstanding the action of oil and moisture and, preferably, high temperatures, and that other special properties are called for when varnishes of classes (C) and (D) are specified.

The remarks on insulating varnishes apply also to insulating compositions for moulded work, from the ordinary pitch and asbestos mixtures to the more efficient products made with high melting resins, more particularly those obtained from the condensation of phenolic bodies with formaldehyde. With such compositions the properties of softening point, inflammability and water-absorption are among the first to be tested by the chemist who is called upon to criticise any such new material.

The manufacture of formaldehyde condensation products for the electrical industry calls particularly for chemical control. The delicacy of the reactions involved, say, in the manufacture of "Bakelite" is well known. Without the chemist such a manufacture is hardly to be undertaken. Chemical checking of the quality of the raw materials and of the exact condition of the condensation products at the various stages in their manufacture, is of paramount importance.

After the condensation product has been prepared the methods of application require to be controlled from the laboratory. Suitable mixtures and processes of mixing can only be made in a uniform manner by means of careful and systematic tests. Faults in manufacture are often in such cases to be explained on chemical grounds, and their prevention and cure can only be guaranteed by the constant attention of the trained chemist.

The extended employment of the chemist in the manufacture of formaldehyde condensation products has resulted in much improved and simplified methods. Control of the reaction has been made more certain, so that considerably increased charges are being worked than was formerly possible, with the result that economy of manufacture in time of operation and labour required has been effected. The plant required has been simplified. For instance, in the final stoving of articles containing phenol-formaldehyde resins it was originally recommended that the temperature of operation should be 140°–180° C. and at pressures of 100 to 150 lb. per sq. in. It is now, however, easy to obtain resins, suitable for impregnating coils, in such a condition that the final non-reactive state can be arrived at by means of lower temperatures and at atmospheric pressure and consequently with less elaborate plant. The time of operation is necessarily increased by this less vigorous treatment. W. S. Flight (*Beama*, 9, 1921, p. 542) quotes a table showing the effect of temperature on the time taken to complete the condensation and polymerisation :—

Temperature ° C.	Time. hrs.
90	14
100	11½
110	9½
120	7½
130	5½
140	3½
150	1
160	30 minutes
170	20 minutes

As a means of checking the condition of the initial condensation of phenol and formaldehyde during its syrupy stage, viscosity values have been used and a large amount of working data has been accumulated controlling these processes. The following table gives some idea of the order of the viscosities looked for by the chemist in dealing with these products :—

Stage of reaction	Viscosity in c.g.s. units
Early	8·6
Intermediate	122
Final syrup	185

In addition to formaldehyde resins the following materials are used in the manufacture of insulating varnishes :—Asphalt and bitumen, stearin pitch, linseed oil and other drying oils, ozokerite, ceresin, paraffin, the natural gums and resins such as copal, dammar, rosin, shellac, and the numerous animal and vegetable waxes. It is not difficult to realise that unless chemical knowledge and skill is made use of in dealing with such a variety of materials troubles inevitably befall the electrical insulating-varnish manufacturer and user. Coffignier ("Les Vernis," 1921, p. 513) has classified the faults often occurring in varnishes when skilled supervision is absent :—

Faults	Possible causes
Lack of drying properties	Wrong proportions of the different constituents. Lack of driers. Wrong boiling of the oil or adulterated oil.
Settling of the varnish	Excess of volatile solvent.
Wrinkling of the varnish	Shortage of volatile solvent.
Streaking of varnish	Excess of drier.
Whitening of the varnish	Poor gums, addition of colophony, and excess of driers.
Dull varnish	Wrong heating of the gums. Lack of elasticity.
Blistering of varnish	Insufficient oil, poor quality of gums.
Varnish exuding grease	Excess of oil.
Cracking of varnish	Poor quality of raw materials.

Insulating varnishes are often used as binding agents for powdery and fibrous materials (so-called "fillers") to form the insulating compounds which are moulded into the various shapes required for insulating fittings in electrical work. Among these "fillers" may be mentioned asbestos, mica, silica, powdered glass, sand, slate, wood and cork dust, and china clay. It is for the chemist to apply chemical principles and examine the respective specific properties so that some order may emerge from this heterogeneous collection of substances. Many of the existing compositions are obtained by the "hit-or-miss" method and do not result from the application of scientific method and knowledge.

This brief and general survey of some of the chemical problems connected with the electrical industry may draw renewed attention to the necessity for making use of chemical knowledge in a realm where engineering has held sole sway.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

CHEMICAL SOCIETY'S LIBRARY

Owing to the work of redecorating the rooms of the Society, the Library will be closed during the entire month of August.

The Library will therefore close on Tuesday, July 31, at 9 p.m., and reopen on Saturday, September 1, at 10 a.m.

The Library, in accordance with the usual practice, will be closed at 5 p.m. from September 1 to 17, on and after which date it will remain open until 9 p.m. every day except Saturday, when it will close at 5 p.m.

ROTHAMSTED LIBRARY

By the courtesy of the Lawes Agricultural Trust, any member of the Society of Chemical Industry on presenting a card from the General Secretary shall be allowed access to this Library. The rules of the Library preclude journals and periodicals from being sent out, and these are therefore always accessible.

A catalogue of the journals and periodicals is in the Society's Offices, at Central House, and may be consulted there by members.

THE FARADAY SOCIETY

On July 13 and 14 a conference on the "Electronic Theory of Valency" was held at Cambridge, the attendance numbering 120 and including several foreign guests as well as representative British chemists and physicists.

The first session, on the afternoon of July 13, was devoted to the application of the electronic theory to the problems of inorganic chemistry. Sir J. J. Thomson, who presided, observed that a limit was set to the number of electrons that one atom could contain. When the number of electrons was small, the octet grouping was particularly stable, but with a different law of force, a sextet might be more stable than an octet. The problem of molecular structure could be best investigated by examining cases of substitution; thus the electric moment introduced in replacing hydrogen by chlorine could be calculated and measurements of the specific inductive capacity of various types of molecules showed that the moment was of constant magnitude. "Valence of the Electrons" was discussed by Prof. G. N. Lewis, who said that Bohr's view that the rare gases from neon to niton and all the stable elementary ions, possessed 8 electrons in the outer shell, fully justified the octet theory. The fundamental phenomenon of chemistry was the formation of pairs of electrons; only about six out of the thousands of known substances contained uneven numbers of electrons. Prof. Lewis then spoke of the conversion of a covalence into an electrovalence, but objected to the use of the term "valence" to express the electrical state of the atom, as he considered the ionised bond was no longer a bond. Papers read by R. H. Fowler on "Bohr's Atom in Reference to the Problem of Covalency," and by Dr. N. V. Sidgwick on "The Nature of the Non-polar Link," led to an interesting discussion in which Sir J. J. Thomson said that two electrons were not necessary to make a bond, as H_2^+ was one of the most persistent aggregates in positive rays, but Mr. Fowler objected that such aggregates appeared incapable of resisting chemical combination. Prof. W. A. Noyes outlined the history of the theory of ionisation and urged that the distinction between polar and non-polar union was one of degree and not of kind, the basic factor in both unions being the pairing of electrons. Sir W. Bragg discussed the lengths of the carbon chains in fatty acids and esters, and advanced explanations for the observations that each additional carbon atom in the alcohol radical increased the length of the carbon chain by 1·22 A.U., whereas the average increase for the acid radical was only 0·97 A.U.

On July 14, applications of the electronic theory of valency to organic chemistry were discussed, Sir R. Robertson presiding. Prof. Lowry showed how the electronic theory enabled two types of valency to be discriminated and said he believed that only two types of valency were needed, the other types of valencies, bonds, etc., being manifestations of electrovalence. Further evidence was needed before a third mechanism of transmission need be admitted. In a paper on "Some Recent Contributions to the Theory of Induced Alternate Polarities in a Chain of Atoms," Prof. Lapworth considered six theories advanced to explain these phenomena and criticised some of the views upheld by Prof. Lowry. Prof. Robinson discussed "Octet Stability in Relation to Orientation and Reactivity in Carbon Compounds," observing, as had Prof. Lapworth, that optical activity was often retained in chemical changes, although it should disappear because the intermediate product, according to convention, would be symmetrical. This retention could be explained by the preservation of asymmetry in one atom by means of partial valencies until stabilised either in the same or another atom. Dr. E. K. Rideal examined the bearing of the theory of polarity on the reactivity of organic compounds, and Mr. R. G. W. Norrish described an experiment in which interaction of bromine and ethylene was almost stopped by lining the vessel containing the gases with paraffin wax, although the gases react at once when in contact with the polar surface of a glass vessel.

During the ensuing discussion, Prof. J. F. Thorpe claimed that the theory of polarity explained everything but predicted nothing, in marked contrast to the stereochemical theories of van't Hoff; a contention which was vigorously opposed by Messrs. Heilbron, Lapworth, Noyes and Robinson. Dr. Flürscheim replied to Prof. Lowry's criticism of his explanation of the influence of substitution on the strength of carboxylic acids, and Prof. Lewis pointed out that breaking a double bond does not necessarily remove *cis* and *trans* isomerism, an observation that was supported by Mr. Bury. In conclusion, Prof. V. Henri presented a remarkable paper on "Molecular Polarity deduced from the Study of Absorption Spectra," in which he concluded that quantified motion may occur in electrons, atoms or molecules, giving rise to broad absorption-bands, narrow absorption-bands and a fine structure of these bands respectively. Many photographs were shown to illustrate the various types of absorption spectra.

ACADÉMIE DES SCIENCES

Prof. Perrin presented two papers at the meeting held on July 23. The first was by Monsieur Job, who explained that the blackening of phosphorescent zinc phosphide is due to a series of intermediary reactions. In the second paper Monsieur Wertenstein indicated that the boiling point of carbon, instead of being, as has been previously thought, the same as that of the electric arc, is much higher; in fact the temperature of the arc has been shown by very accurate measurements to be 3500° C., and by applying the formula of Clapeyron, M. Wertenstein has shown that the temperature of boiling carbon is 5000° C. A note by MM. Demolon and Boischot was presented by M. Lindet. This note attributed the inactivity of peat towards biological reactions not to toxins or to protozoa, but to the lack of food materials.

PERSONALIA

Prof. J. Reid, M.A., Ph.D., professor of organic chemistry (pure and applied) in the University of Sydney, has been appointed to succeed Prof. Robinson in the chair of chemistry at the United College and in the directorship of the chemistry research laboratory in the University of St. Andrews.

Monsieur F. Bollaert, president of the board of directors of the Mines de Lens, has been nominated president of the Conseil d'Administration des Forges et Aciéries du Nord et de l'Est.

Dr. A. T. McPherson has been appointed associate chemist in the Bureau of Standards, to investigate rubber and gutta percha as insulating materials.

Mr. A. L. Burns has been appointed chief of the New Orleans Food Investigation Station of the United States Bureau of Chemistry.

Dr. S. C. Lind has been appointed chief chemist and chief of the division of mineral technology of the United States Bureau of Mines, to succeed Dr. R. B. Moore, and Mr. E. S. Leaver has succeeded Dr. Lind as superintendent of the rare and precious metals experimental station at Reno, Nevada.

Dr. H. Nicklas has been appointed professor of agricultural chemistry at the *Hochschule* for agriculture and brewing at Weihenstephan; Dr. A. Benrath has been appointed to a professorship in the Aachen Technical *Hochschule*; and Dr. J. Herweg has been nominated to a chair in the Hannover Technical *Hochschule*.

* * *

From Germany the following deaths are announced:—Dr. H. Scholl, professor of Applied Physics in the University of Leipzig; F. C. Correns, director of the Accumulatoren-Fabrik A-G.; Dr. K. Klimmer, director of the Deutschen Solvaywerke, Osternienburg (Cöthen); Prof. F. Krafft, of the University of Heidelberg; Dr. H. Liebmann, chemist to the Bayer Co. at Leverkusen; Dr. F. Collischonn, director of the Verein für Chemische Industrie A.-G., Frankfort; Dr. C. Hess, director of F. Bayer and Co.; and Dr. A. Ellinger, professor and director of the Pharmacological Institute of Frankfurt.

CORRESPONDENCE

THE "VINEGAR PLANT"

Sir,—Your editorial suggestion to sow vinegar plants among the lettuces was very rich, but *Biochemist's* comment thereon is far richer.

As a humble, but regular, reader may I beg that such *jeux d'esprit* be always given to the world as being too priceless to be lost ? Some of our biochemists should try to cultivate another rare but fragrant plant, humour.—I am, Sir, etc.,

Reginald G. Johnston
Scientist in Charge.

Midland Laboratory Guild, Ltd.,
Birmingham. August 4, 1923.

A CORRECTION

Mr. F. J. Cooper calls attention to one point in our review (in the issue of July 27) of his book, *Textile Chemistry*, and states that he had sufficiently distinguished between the work of Mercer and the mercerising process as carried out at the present day. From the quotations mentioned it is evident that Mr. Cooper has some ground for complaint, but our reviewer writes that he does not think the fact is sufficiently emphasised that Lowe's discovery of the lustring of cotton by means of caustic soda is quite distinct from any previously known process. In short, mercerising of to-day is wrongly named.

GERMAN IRON-ORE CONSUMPTION

Through the loss of Lorraine and Eastern Upper Silesia, Germany is now in possession of only 74·3 per cent. of its former iron-ore reserves. Political causes have led to the development of home deposits and to increased imports from other countries, particularly Scandinavia, as is shown in the following table, which gives the quantities imported from certain countries and the percentages of the total for the year :—

Source	1913 1000t.	Per cent.	1920 1000t.	Per cent.	1922 1000t.	Per cent.
France (incl. Lorraine) —	5,000	33	1,183	20	2,069	18·7
Luxembourg ..	—	—	1,331	22·5	766	7·0
Scandinavia ..	4,867	32	2,725	46·1	5,508	50·0
Spain ..	3,632	24	585	9·9	1,339	12·1
America ..	121	1	—	—	350	3·2
Africa ..	618	4	—	—	681	6·2
Other Countries ..	975	6	91	1·5	311	2·8
Total ..	15,213	100	5,915	100·0	11,014	100·0

The home production of ore in Germany was about 5 mill. tons in 1913 and 5·16 mill. t. in 1920. The use of German ores increased very largely in 1922. The increasing use of high grade Scandinavian ores has important possibilities in respect of fuel economy.

NEWS AND NOTES

CANADA

The Mining Industry in Quebec

The general condition of the mining industry in Quebec at the end of the past year showed a decided improvement as compared with the beginning of 1922, when it was at a low ebb. Although still far from normal, the industry is much healthier than it was a year ago. The total value of the mineral production of the Province of Quebec in 1922 was $17,898,062, an increase of $2,375,074, or 15 per cent., as compared with the figures for 1921, when the value was $15,522,988, the lowest recorded since 1916.—(*Official.*)

UNITED STATES

Cadmium in 1921 and 1922

The production of metallic cadmium in the United States in 1921 decreased to 65,101 lb. (129,283 lb. in 1920), whereas the production of cadmium sulphide increased from 32,133 lb. to 65,446. Prices of the metal decreased considerably, but that of the sulphide fell only slightly. Imports amounted to only 101 lb. ; no exports were recorded, but it is known that a considerable quantity was shipped abroad. The production in 1922 rose to 131,509 lb. of metal and 134,774 lb. of sulphide, prices rising in sympathy. Further progress is reported in the application of the Udylite process of cadmium plating, more than 50 plants being in operation at the end of 1922, new installations taking place at the rate of six to eight a month No progress was made in the production of the pigment cadmium lithopone, as only experimental quantities were produced. A source of intense monochromatic red light for use in physical investigation has been developed by the Bureau of Standards in the new quartz cadmium vapour lamp. Competition from cadmium produced by the electrolytic plant at Risdon, Tasmania, is said to have seriously disturbed United States producers. (*Cf. J.*, 1921, 234 R.)

FRANCE

The Sugar and Fermentation Industries

On the occasion of the 122nd anniversary of the Société d'Encouragement pour l'Industrie Nationale, Monsieur L. Lindet described the present state of the reconstruction of the agricultural industries in the devastated regions. Out of 213 factories producing 100,000 metric tons of sugar per 24 hours, 148 were destroyed, representing a loss of 6800 t. of sugar per day ; 66 of these destroyed factories have been restored and are now producing 32,000 t. per day. Of the remaining factories 110 have been grouped in twos, fours, eights, or even thirteens, the grouping being usually accompanied by an increase in the productive capacity. Out of 300 distilleries, 152 were destroyed, representing over 50 per cent. of the French output in 1913. Here, however, reconstruction is slow, as alcohol (exception being made of the quantities necessary for industry) can only be imbibed. Since June 30, 1916, the State has created a monopoly of industrial alcohol, and thus has greatly decreased alcoholism. Alcohol in excess of requirements will be used for making "national fuel." Out of 2570 breweries, 1767 were destroyed, but the present production has attained 78 per cent. of the pre-war level, although the French consumption of beer has decreased, the tendency being to produce low-gravity beer.

The Congress of Industrial Heating

This Congress was held at Paris from June 10 to 20 and also included an exhibition similar to that held last year on the occasion of the Congress on Liquid Fuels. Amongst the questions treated by the Congress were: "The Utilisation of Mine Waste and of Poor Fuels," "Fuel Briquetting," "The Study of Ash" and "Powdered Fuels." The meetings on June 14 were devoted to the papers of the English delegates presented by Dr. Lander, director of the Fuel Research Board, who described the work of that organisation, whilst Prof. Wheeler spoke of his experiments on the reactivity and combustibility of coke. Dr. Marie Stopes described her work on the constitution of coal, and Mr. Lomax also described the work done in Cheshire and Lancashire on the same subject. At other meetings of the Congress, the questions discussed included "The Measurement and Control of Heating," "The Scientific Definition of Heat and of Temperature," "Calorific Power," "Experiments on Boilers and Furnaces," "Investigation of Refractory Production and Special Materials," and "The Use of Crude Oil as Fuel in the Pottery Industry." Visits were paid on June 18 to mines in the Pas de Calais district and on June 19 and 20 to gas works in the Parisian region and to the boiler factory of Babcock and Wilcox. The exhibition illustrated the practical application of the conceptions discussed during the Congress, particularly plant for producing and conserving heat, and controlling and measuring apparatus.

GENERAL

Gas Undertakings in Great Britain

The Board of Trade has issued Part I. of the Return relating to authorised gas undertakings in Great Britain during 1922 (H.M. Stationery Office, 5s. net). This book gives particulars of the manufacture and supply of gas by nearly 800 undertakings. Part II., which is not yet issued, will deal with the finance of the undertakings and the prices of gas. During 1922 authorised undertakings in Great Britain manufactured 252,070 million cb. ft. of gas, of which 80 per cent. was coal and nearly 18 per cent. water gas. Excluding consumption at the gas works, the quantity sold was 232,603 million cb. ft., as against 229,077 million cb. ft. in 1921, and the residual products included 10,475,000 tons of coke and breeze, and 167,771,000 gallons of tar. The figures show there are nearly 8,000,000 consumers. The Return gives details of the make of gas materials used, quantities of residuals made, and the number of consumers for each of 796 undertakings.—(*Official.*)

The Chemical Industry in Poland

Before the war the Polish chemical industry was not of great importance, and during the war the existing factories suffered heavily. Since then reconstruction has progressed vigorously, so that the chemical industry is becoming more and more independent of supplies from abroad, particularly from Germany, England and France. The country is particularly favourably situated for the creation of a strong chemical industry owing to the important deposits of salt, coal, petroleum, and other raw materials in Galicia, the abundant water power, and the already developed productive capacity of Upper Silesia, which manufactures large quantities of sulphuric acid. On January 1, 1923, there were 120 factories finding employment for 15,875 persons, and other factories are being built, particularly in former Prussian territory.

The following figures of the productive capacity per annum of some of the more important branches will give an idea of the state of the industry:—*Inorganic chemicals:* Ammonia soda, 70,000 metric tons; caustic soda, 8000 t.; sulphuric acid, 50,000 t.; superphosphates, 60,000 t. *Electro-chemical products:* Carbide, 3000 tons; bleaching powder, 500 t.; caustic soda, 1200 t. *Dyestuffs:* The production totals 150 tons per month, part being manufactured from imported intermediates. *Wood-distillation products:* Wood charcoal, 15,000 t.; acetate of lime, 1600 t.; wood spirit, wood tar, rosin and turpentine, 350 t. About 1000 cartloads of bones are worked up each year, yielding 6000 tons of bone-meal as well as other products. There are sixteen match factories employing 3000 workers, and the monthly production amounts to 50,000,000 boxes, of which 15 per cent. is exported. The single artificial silk factory provides employment for 4000 workers and produces 1500 kg. of artificial silk per day, most of which is consumed locally.—(*Chem. Ind.*, 46, *No.* 17.)

Oil-shale Firing in Esthonia

The technique of firing boilers with Esthonian oil-shale appears to have reached such a pitch that hopes have been raised that coal imports might be considerably reduced, with important results to the finances of the country, though it is unlikely that imported coal will ever be dispensable. In practice the utilisation of the shale deposits will have to be carried out either by gasification of the shale or by utilising it to generate electrical power; in any case the low calorific value of the natural shale renders transport unprofitable.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Aug.* 2)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Steel wire, corrugated sheets	157
Australia	Surgical dressings, drugs, chemists' sundries	126
British India	Steel, copper, malleable cast-iron (tender)	*
British West Indies	Leather goods	131
Netherlands	Domestic hollow-ware	145
Norway	Steel and brass tubes	146
Yugoslavia	Copper and brass sheets, tin ingots	147
Spain	Druggists' sundries	148

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, London, S.E. 1.

TARIFF CUSTOMS EXCISE

Germany.—The specific taxes on lighting apparatus, including electric incandescent lamps and burners for Nernst lamps, mercury-vapour lamps, carbons for electric arc lamps and incandescent mantles, are altered to an *ad valorem* tax of 20 per cent.

The sugar tax is increased to 24,000 marks per 100 kg. of starch sugar and 60,000 marks per 100 kg. of other sugar.

Madagascar.—The treatment to be accorded to imported compound medicines is to be modified in accordance with a Decree issued by the Governor-General of Madagascar and Dependencies.

Portugal.—The ordinary rates of customs duty are now payable on the following articles, owing to the termination of the Franco-Portuguese *modus vivendi* :—Malleable iron and steel, dyeing extracts, substances for use in medicine and perfumery, instruments, implements and tools, rubber tyres, medicines, medicinal extracts, etc.

Tariff Revisions.—The issue of the *Board of Trade Journal* for August 2 contains a special article devoted to the revision of the Customs Tariffs in various countries, including changes made or pending since the end of 1921. Most European countries are affected, save Holland, and changes have been or are to be made in most of the Colonies, the United States, South American Republics, China, Japan, etc.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Imports of Russian Petroleum

Answering Captain Morcing, Sir P Lloyd-Greame said that the imports of petroleum into the United Kingdom from Russia during 1921-1922 amounted to 10,480,601 gallons. of which 9,081,555 galls. were from Batum and none from Novorossisk. He was unable to say how much of the petroleum was produced from wells owned or developed by English capital.—(July 31.)

Dyestuffs

Sir. P Lloyd-Greame, replying to Mr. Collison (who asked whether he was aware that users in Japan of 99-100 per cent. synthetic indigo could buy from British dye makers at 5s. per lb., whereas 8s. 6d. was charged to the British user and that this difference in price was due to the fact that British dye makers have a monopoly in this country both in manufacturing and in the distribution of imported German dyes), said that he had been informed by the only British makers of synthetic indigo that none of that product was being sold by them in Japan.—(July 31.)

Merchandise Marks Bill

In a written answer to Mr. Hannon, Sir P. Lloyd-Greame said that the question of a suitable time for introducing the Merchandise Marks Bill was under consideration, but he did not think it would be possible to proceed with it during the Autumn Session.—(July 31.)

Coal Supplies of France

Lieut.-Colonel Lane-Fox, in a written answer to Mr. W. Thorne, gave the following figures showing deliveries of German coal and coke to France for 1922-1923 and purchases of English coal and coke by France, in tons, for the same period :—

	1922 metric tons	1923 metric tons
Delivered by Germany at French Frontiers :—		
Coal	4,247,483	643,372
Coke	4,338,943	722,087
Lignite briquettes	490,299	69,447
Imported by France from Great Britain :—		
Coal	13,891,483	10,683,000
Coke	72,552	341,000
Briquettes	151,359	81,000

—(July 31.)

Sulphate of Ammonia (Export Regulations)

Viscount Wolmer, in a written answer to Mr. Shinwell, said that the official control of the export of sulphate of ammonia, instituted during the war, was now at an end, and the export was, accordingly, subject only to the ordinary customs regulations which he had no reason to think were not being observed.—(Aug. 1.)

Lead Poisoning in Electric Accumulator Works

Replying to Lord H. Cavendish-Bentinck, Mr. Bridgeman said he was aware of the number of cases of lead poisoning in electric accumulator works which were reported by the Factory Department. The matter had been taken up strongly with the firms, which were re-organising the departments affected. The cases mostly occurred amongst workers newly engaged, and were not serious. The Factory Department had for some time been dissatisfied with the results obtained under existing Regulations and a special inquiry was commenced some time ago to see in what respects the Regulations could be strengthened. This inquiry had now been completed and further action would be considered in the light of its results. The Chief Inspector was satisfied that the increase of lead poisoning cases in the works in question was not attributable in any way to any lack of inspection.—(Aug. 2.)

REPORTS

Report on the Industrial, Commercial, and Economic Situation in Poland. Dated February, 1923. *By* R. E. Kimens, *H.M. Commercial Secretary, Warsaw. Pp.* 48. *Department of Overseas Trade. H.M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

The events of most importance in the economic life of Poland during 1922 were the incorporation of a portion of Upper Silesia and the deterioration of the financial situation due to depreciation of the currency. Nevertheless, most industries were prosperous, and with the large industrial resources of the newly acquired territory, all the necessary assets for recovery from the present financial situation are at hand. The Upper Silesian area contains most of the Silesian coal resources, as well as highly developed chemical, zinc, iron and steel industries.

In general, industries improved in 1922, though in Upper Silesia transport difficulties reduced output when the region was first taken over. The output of pig-iron reached 40 to 60 per cent. of the pre-war figure. The cement industry made satisfactory progress in spite of depression in the building trade, on account of increased application at home and also to the growing export trade. Poland is now an important mining country. The coal output in the first three quarters of 1922 exceeded that of 1921 by 26 per cent., but the production of lignite in these periods fell from 195,259 t. to 155,729 t. The output of zinc in 1922 was maintained at the 1921 level, ore being raised at the rate of about 60,000 t. per annum. Important potash resources are being developed, but the salt deposits of the country could be further exploited. The output of petroleum decreased from 586,257 t. in 1921 to 517,873 t. in 1922, largely owing to the disappointing results given by the new Horodyszeze and Mragnica fields. The output of alcohol increased from 15,838,000 gallons in 1921-2 to 31,676,000 galls. in 1922-3, largely owing to the abundant potato crop. An increase in the area under sugar-beet led to an output of 320,000 t. of sugar, compared with 225,000 t. in 1921. The crops in 1922 were very satisfactory and more than sufficient for home needs. It is considered that, notwithstanding the advantage held by countries with a low "valuta," it should be possible by means of suitable organisation for British merchants to compete in Polish markets.

Report on Economic Conditions in Rumania, March, 1923. *By* A. Adams, *H.M. Commercial Secretary, Bucarest. Department of Overseas Trade. Pp.* 62. *London: H.M. Stationery Office.* 1923. *Price* 2*s.*

The situation in Rumania is still unsatisfactory, though some efforts were made during the year under review to improve the financial condition of the country (*cf.* J., 1922, 335 R). Since the armistice Rumania has had an adverse trade balance, and there has been no encouragement to foreigners to invest capital in the country, as large sums are owing abroad by Rumanian traders.

The petroleum industry is of great importance, though at present labouring under some difficulties arising out of the war. In 19 the production of crude oil was 1,137,184 tons, against 1,168,414 t. in 1921. Drilling was handicapped by lack of electric power, shortage of labour, and bad weather, though more was done than in 1921. Up to September 30, 1922, 910,095 t. had been treated at the refineries, producing 214,538 t. of benzine, 159,234 t. of lamp oil, 82,493 t. of gas oils, etc., and 433,831 t. of residues. The internal consumption in the same period was 604,791 t., while 315,512 t. were exported. Statistics of the mining production of Rumania for 1922 are not yet available, but in 1921 there were obtained 1,594,719 t. of lignite, 209,968 t. of coal and anthracite, whilst iron, copper, lead, manganese, and antimony were also mined.

In 1922 the tendency to make quotations for international trade with Rumania in pounds sterling increased. To some extent a departure is being made from the credit system, importers paying in cash. No complete figures are available for imports or exports in 1922. Among the exports, however, cereals, petroleum products, and timber are most important.

A committee was appointed during the year to advise the Minister of Industry and Commerce as to the constitution of joint-stock companies and of branches of foreign trading companies. Owing to delay on the part of the committee in formulating a policy, hindrance has been caused to the foreign merchant in obtaining the necessary permission to trade.

REVIEW

A Treatise on Chemistry. *By* The Right Hon. Sir H. E. Roscoe, F.R.S., *and* C. Schorlemmer, F.R.S. *Vol. II.* The Metals. *Parts I & II. New edition, completely revised by* B. Mouat Jones *and others. London: Macmillan & Co., Ltd.,* 1923. *Price 50s., 25s. each volume.*

The position of Roscoe and Schorlemmer's monumental Treatise as a standard text-book on Inorganic Chemistry is now so well assured that no words of commendation are needed to extol its merits. It is without question the leading work in the language on the subject of which it treats. Its excellence is due, in the first place, to its plan and arrangement, to its comprehensiveness, wealth of detail and accuracy of statement, to its admirable illustrations, its attractiveness of style and the manner of its presentation in the matter of paper and printing. Originally published in 1878, no pains have been spared to keep it up to date and to maintain its reputation as a faithful reflex of contemporary knowledge. The books under review are now in their sixth edition, the last edition having appeared in 1913, when the late Sir Henry Roscoe, as the survivor of the original authors, superintended its preparation, in which he was assisted by Professor Philip, Mr. P. V. Barker, Dr. Makower, Messrs. Spencer and Baker, and Drs. Keane and Mollwo Perkin—all eminent authorities in the several departments of the science which they undertook to revise.

During the ten years which have elapsed since the publication of the fifth edition, many important changes have occurred, and considerable additions have been made to our knowledge of the chemistry of the metals and their compounds. Practically a new chemistry and a new physics have arisen in the interval. As Mr. Mouat Jones points out in the preface which accompanies the new edition, great advances have been made in our fundamental ideas of atomic and molecular structure, of valency, and of chemical affinity, and in the interpretation of the Periodic Law, largely as the result of the rapid development of the science of radioactivity, and of the introduction of new methods of investigation, notably of positive ray analysis and X-ray spectroscopy. No attempt is, however, made to give a complete account of the new theories in the present volumes, as these are held to be mainly devoted to a systematic account of the metals and their compounds. At the same time such matters as the classification of the elements, valency, atomic numbers, isotopes, atomic structure and spectrum analysis have received attention and have been revised by Mr. L. J. Hudleston. The section on crystallography has again been dealt with by Mr. Barker. Professor Bannister has also revised the metallurgical sections and Dr. Makower that on the radioactive elements. Special groups of the metals have been entrusted to Professor J. F. Spencer and Messrs. Eldridge, Bury and Howell.

Of the two volumes under review the first is concerned with the discussion of the general principles already referred to, such as the modes of determining the atomic weights of the metals, the fixation of their equivalents, the molecular weights of their compounds; atomic heat and molecular heats, isomorphism and its bearing on molecular weights; valency of the elements, their classification and natural arrangement; the periodic system, chemical properties, valency and physical properties in relation to the periodic system; atomic numbers, isotopes, structure of the atom; crystalline forms of the metals; colloidal solutions; alloys and amalgams; constitution of salts, acids and bases; metallic oxides, hydroxides and salts; solubility, fusibility and volatility of salts, generic properties of salts; chemical change and the law of mass action; the spectroscopy of the metals and their compounds. The section on crystallography deals with the symmetry of crystals, enantiomorphism, the optical, thermal and electrical properties of crystals, polymorphism, crystallochemical analysis, crystal structure, and chemical crystallography. A comparison of the present methods of dealing with these subjects with that employed in the earlier editions, and especially with that of the edition of 1878, reveals the extraordinary growth of knowledge which the last four decades has witnessed, not so much, perhaps, in minor details respecting the discovery of additional metallic compounds and the elucidation of their chemical and physical properties as in the establishment of the broad general principles which govern the mutual relations of the metallic elements. It is on questions relating to what may be termed the chemical philosophy of the metals that the most striking advances have been made. The remaining portion of Part I deals with the systematic description of the metals and their derivatives; of Group I (the alkali metals), Group II (the alkaline earth metals) and Group III (the aluminium group) of the periodic system. In the accounts of the several metals of these groups due attention is paid to their technical applications and that of their compounds, and we have accordingly adequate and up-to-date descriptions of alkali manufacture, the metallurgy of copper, silver and gold, the manufacture of glass, earthenware, pottery and porcelain, and the industrial applications of the compounds of the metals of the rare earths. As regards Group I, advantage has been taken of the analogies existing between ammonium compounds and those of the alkali metals properly so-called to include accounts of hydroxylamine and hydrazine salts which, although strictly speaking not metalline substances, have doubtless as much right to be so regarded as the derivatives of ammonia. To remove these substances from the section on organic chemistry is a new departure which can only be justified on the ground of its convenience. They at least serve to illustrate the essentially irrational nature of the sub-division of chemical compounds into organic and inorganic derivatives.

Part II of Volume II deals with Groups IV, V, VI, VII and VIII of the metals, and with the sub-groups into which these are divided. As in the previous volume the modes of extraction, metallurgy, and technical applications and methods of manufacture of industrially important derivatives are treated in adequate detail, and the various processes are illustrated when required by suitable diagrams and figures. Indeed, the wealth and character of the pictorial material in the volumes remains, as hitherto, one of the most commendable features of the work. As regards its technology it is evident that every effort has been made to bring it up to date. From the very outset of its existence the work was characterised by its judicious mixture of sound and accurate science with a keen appreciation of the material benefits of its practical application, and this characteristic, which was zealously preserved in the successive editions for which Sir Henry Roscoe was mainly responsible, has been maintained in the present issue.

It may be interesting to recall the circumstances which led to the inception and existence of this treatise as these are known to the writer of this notice. In a sense the work may be said to owe its origin to the famous report of the Duke of Devonshire's Commission on the teaching of science, and especially physical science, in our schools and colleges. At the date of the issue of the Commission the importance of science as an educational instrument was hardly recognised by those who directed and controlled our educational systems. Education in our public schools and Universities was largely under the influence of a medieval system which had suffered no material change since the revival of learning in the Middle Ages. Whilst classical learning and scholarship continued to be deservedly fostered, there had grown up a new knowledge based upon the systematic study of natural phenomena. This knowledge was found to be rich in its potentiality of material benefit to mankind. It was capable of adding enormously to the welfare of humanity. But strangely enough our educational system failed to recognise this fact fully. The public mind was gradually led to appreciate it by the lessons of successive international exhibitions beginning with the celebrated exhibition of 1851. A careful comparison of the progress made in the industrial applications of science, as shown in the various exhibitions which followed that of 1851, revealed that our commercial and industrial supremacy was seriously threatened in consequence of our apathy and by our continued neglect to realise the importance of physical science as a factor in national progress. The public mind was greatly perturbed. It was gradually recognised that the fault was mainly due to our educational system. It was on too restricted a scale and wholly failed to adapt itself to the changed conditions of modern life as shown in the application of the new knowledge which had been accumulated with marvellous results over a period of time, comparatively limited as history goes. The Royal Commission already alluded to was the outcome of the agitation of the public mind. The effect of the Commission's report was profound and immediate and led to what was practically a revolution in our schools and University systems. One result was the creation of a special class of school literature. It was the absence of books suitable for class instruction which was one of the causes of the neglect of science teaching in our schools and colleges. Enterprising publishers, like the eminent firm to whom we owe the issue of the volumes now noticed, recognising the trend of public sentiment, were quick to realise the importance of supplying a demand now regarded as inevitable, and under the able guidance of Huxley, Roscoe and Balfour Stewart as editors, books in almost every department of physical science which lent itself to class instruction in schools soon made their appearance. Roscoe's Lessons in Elementary Chemistry was phenomenally successful and rapidly ran through successive editions. It was widely adopted in each of our public schools, which in deference to public opinion, adopted what came to be known as a " modern side." The book was translated into practically every European language and into a number of the languages of the East, and in spite of the competition of a host of imitators it still remains a favourite text-book for class instruction.

The success of this venture induced Roscoe to attempt the compilation of a work more suitable for advanced instruction and for the needs of secondary schools and Universities. For this purpose he associated himself with his friend and colleague, Carl Schorlemmer, then lecturer and subsequently Professor of Organic Chemistry at Owens College, Manchester. No selection could be more happy. Schorlemmer was a remarkably well-read man with a profound and accurate knowledge of the literature of chemistry. He was an excellent and judicious critic who wrote our language with ease and precision. To him is mainly due the historical introduction largely based upon the classical history of Hermann Kopp, which constitutes the initial portion of the treatise, and he contributed extensively to the descriptive sections of the work.

The Treatise on Chemistry is, and will remain, the most enduring monument to the genius for organisation, capacity and industry of its projector. To him is mainly due not only its inception, but the details of its plan and arrangement. It was one of the earliest works of its kind to recognise the value of the Periodic Law as a system of classification, and the book is a striking exemplification of the value of Mendeleeff's great generalisation.

So long as the work continues to be revised and edited with the care and judgment displayed in the volumes before us, so long will its pre-eminence as a standard treatise be assured, and so long will Roscoe's memory as the prime mover in its creation be preserved and perpetuated.

T. E. Thorpe

Technical Methods of Ore Analysis. *By* Albert H. Low, Sc.D. *Ninth edition. Pp. xlix+348. London; Chapman and Hall, Ltd.*, 1922. *Price* 17*s.* 6*d.*

For the purpose of making this well-known book better adapted to the requirements of students, the author has devoted some 38 pages of the present edition to suggestions regarding the training of students in rapid technical analysis, to a specimen lecture and to methods for the determination of 16 elements, fully detailed and in the author's step demonstration method. This new matter is in the form of an introductory chapter, and the arrangement, as well as additional notes throughout the book of an explanatory nature, are introduced in such a way as not to be the least source of annoyance to the technical chemist. The present edition has been entirely rewritten and is a considerable improvement on the 8th (1919) edition. Much of the appendix in the latter has now been transferred to the text, and the miscellaneous determinations have now increased from 2 to 10 in number. The factors have been brought up to date and based on the International Atomic Weights for 1921. The book is well got up and contains remarkably few printers' errors. It can be confidently recommended to teachers as well as to the technical chemist, to whom it has been known, through past editions, as an authoritative and practical guide.

COTTON RESEARCH AND SOIL PROBLEMS

The Empire Cotton Growing Corporation has made a grant of £1000 for five years to the Rothamsted Experimental Station to investigate the fundamental physical properties of the soil and other problems likely to be of importance in connexion with cotton growing. The soil physics department at Rothamsted will undertake these investigations as part of its general research work on the fundamental properties of the soil, and the money will be used to increase the staff and equipment so that progress may be made more rapidly.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business in the home and export markets remains very restricted. Makers' prices are practically unchanged in spite of the unpromising nature of the outlook. The demand from the textile trades is particularly poor, and in general practically no interest is displayed in forward purchasing.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric ..	3s. 6d. - 5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw. ..	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d. - £8 per ton. Comparatively good demand.
Arsenic (White) ..	£72 - £73 per ton. Not much doing.
Bleaching Powder ..	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Quiet.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate ..	£27 per ton.
Potash Caustic	£30 - £33 per ton. Poor demand.
Potass Bichromate ..	5¾d.-6d. per lb. d/d.
Potass. Chlorate ..	3d. per lb. Very dull.
Salt Cake	£4 10s. - £5 per ton. Remains a very firm market.
Soda Caustic 76% ..	£19 - £21 10s. according to quality. Fair business.
Soda Crystals	£5 5s. - £5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24 per ton. Very scarce for spot delivery.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	2⅞d. - 3d. per lb. Very dull.
Sod. Nitrate refd. 96%..	£13 5s.-£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.

Sod. Sulphide conc. 60/65	About £15 per ton. Rather lower in value but very quiet.
Sod. Sulphite, Pea Cryst.	£16 10s.-£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.-1s. 3d. per lb.
Crimson	1s. 6d.-1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25-£29 per ton according to quantity.
Carbon Black	Cheaper at 10½d. - 1s. 1d. per lb. Ample supplies now available.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.-6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16-£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

In sympathy with most trades, this market is now a little easier.

Acetate of Lime—	
Brown	£11 5s. - £11 10s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8 - £10 15s. per ton d/d, according to locality of market and type of charcoal. Demand easier.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2s. per gall. 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P. Firm market as to price but demand quiet.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5-£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d. per lb. spot. 1s. 1½d. per lb. for forward delivery
Crude 60's	3s. - 3s. 6d. per gall. Market firmer for early delivery.
Acid Cresylic—97/99	2s.-2s. 5d. per gall. Steady demand.
Pale 95%	1s. 10d.-2s. 4d. per gall.
Dark	1s. 10d. - 2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d - 11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8¼d.-9d. per gall.
Benzole—	Market uncertain. Prices doubtful.
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall. Business slack, abundant supplies.
Pure	2s. 1d. - 2s. 2d. per gall.
Toluole—90%	1s. 8d.-2s. per gall. Not many inquiries.
Pure	2s.-2s. 4d. per gall. Not much inquiry.
Xylol	2s. 3d. - 3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d.-1s. per gall. Not much business.
Middle Oil	8½d. - 9d. per gall. Market steady. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.-9d. per gall.
Solvent 90/160	1s. 5d. - 1s. 7d. per gall. Quiet.
Solvent 90/190	1s. 4d. - 1s. 7d. per gall. Market quiet.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business passing.
Whizzed or hot pressed	£11 - £13 per ton. More inquiries.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton
Pitch, medium soft	140s.-150s. per ton. Autumn delivery. Market steady.
Pyridine—90/140	18s. per gall. Demand good.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Depression in the textile trade continues, but business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb.
Acid Sulphanilic	1s. 1½d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	5s. 3d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.-6½d. per lb. Quiet.
m-Cresol 98/100%	2s. 1d.-2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.-2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
d-Dichlorbenzol	£70 per ton.

Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.-9d. per lb. naked at works.
66/68	1s. 2d.-1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains exceptionally dull and orders continue to be very scarce.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. per lb. for cwt. lots. Market steady.
Acid, Benzoic	2s. 3d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 8d. per lb., less 5%. Demand improved.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.-2s. 3d. per lb. Limited demand.
Acid, Tannic	3s. 1d. per lb. would now be accepted.
Acid, Tartaric	1s. 3d.-1s. 3½d. per lb., less 5%. Demand below normal but improving. Stocks accumulated during the cold spring now being used up and a rise in price not improbable.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very weak.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.-3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	19s. per lb. now quoted with little inquiry.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31-£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source.
Calcium Lactate	2s. 6d. per lb. for best makes.
Chloral Hydrate	3s. 9d. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots. Very firm. Higher prices expected.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	£96 per ton. Quiet.
Guiacol Carbonate	8s. 6d. per lb. Spot supplies short.
Hexamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	70s.-80s. per cwt., according to quality and quantity.
Menthol	38s. per lb. spot, less 2½%. Slightly weaker.
Mercurials	Very much weaker.
Methyl Salicylate	2s. 3d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Morphine	Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d. Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb.
Phenacetin	6s. per lb. Lower in value.
Phenazone	7s. per lb. In better demand, especially for small quantities.
Phenolphthalein	6s. 9d. per lb. Firmer. Supplies short.
Potass. Bitartrate—99/100% (Cream of Tartar)	94s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.-3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d. - 2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 8d. per lb. Very quiet. Lower in value.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s. 3d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 6d. per lb., and Crystal at 2s. 7d. per lb. Market stagnant.
Sod. Sulphite, anhydrous	£27 10s.-£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.

Sulphonal	14s. per lb.	
Tartar Emetic	1s. 2d.-1s. 4d. per lb.	
Thymol	15s. 6d. per lb. for cwt. lots of natural recryst.	

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.	
Aubepine	14s. ,, ,,	
Amyl Acetate	3s. ,, ,,	
Amyl Butyrate	7s. 3d. ,, ,,	
Amyl Salicylate ..	3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,	
Benzyl Alcohol free from Chlorine	3s. ,, ,,	
Benzaldehyde free from Chlorine	2s. 9d. per lb.	
Benzyl Benzoate ..	3s. 3d. ,, ,,	
Cinnamic Aldehyde ..	18s. 6d. ,, ,,	Advanced.
Coumarin	18s. 6d. ,, ,,	
Citronellol	19s. 6d. ,, ,,	
Citral	9s. 6d. ,, ,,	
Ethyl Cinnamate ..	15s. ,, ,,	Cheaper.
Ethyl Phthalate ..	3s. 9d. ,, ,,	,,
Eugenol	11s. ,, ,,	
Geraniol (Palmarosa) ..	32s. 6d. ,, ,,	Advanced.
Geraniol	5s. 6d.-12s. 6d. per lb.	
Heliotropine	8s. per lb.	
Iso Eugenol	16s. 6d. per lb.	
Linalol ex Bois de Rose ..	21s. ,, ,,	
Linalyl Acetate	21s. ,, ,,	
Methyl Anthranilate ..	7s. ,, ,,	
Methyl Benzoate ..	8s. 6d. ,, ,,	
Musk Xylol	11s. ,, ,,	Dearer.
Phenyl Ethyl Acetate ..	10s. ,, ,,	
Phenyl Ethyl Alcohol ..	17s. 6d. ,, ,,	
Rhodinol	45s. ,, ,,	
Safrol	2s. 4d. ,, ,,	
Terpineol	3s. 1d. ,, ,,	
Vanillin	22s. 3d.-23s. 6d. per lb. Firm with steady demand.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	2s. ,, ,,	
Bergamot Oil	12s. 6d. ,, ,,	spot.
Bourbon Geranium Oil ..	29s. ,, ,,	
Cananga Oil, Java ..	9s. ,, ,,	
Cinnamon Oil, Leaf ..	4½d. per oz.	
Cassia Oil 80/85% ..	11s. 6d. per lb.	
Citronella Oil—		
Java 85/90% ..	4s. 2d. ,, ,,	
Ceylon	3s. 8d. ,, ,,	
Clove Oil	8s.-8s. 6d. per lb.	
Eucalyptus Oil 70/75%	1s. 10d. per lb.	
Lavender Oil, Mont Blanc 38/40% ..	13s. ,, ,,	
Lemon Oil	3s. 1d. ,, ,,	
Lemongrass Oil	2¾d. per oz.	
Orange Oil, Sweet ..	13s. 7d. per lb.	
Otto of Rose Oil—		
Anatolian	24s. per oz.	
Bulgarian	30s. per oz.	
Palma Rosa Oil ..	19s. per lb.	
Peppermint Oil—		
English	80s. ,, ,,	
Wayne County ..	13s. ,, ,,	
Japanese	7s. 1½d. ,, ,,	Advanced.
Petitgrain Oil	7s. 3d. ,, ,,	

TRADE NOTES

British Industries Fair, 1924

It is announced in the *Board of Trade Journal* of August 2 that the organising authorities for the London and Birmingham sections of the British Industries Fair have decided not to hold the Fair at the end of February, 1924, but to postpone its opening in London till April 28 (continuing until May 9), and to open the Birmingham section on the Monday following the closure of the Fair in London. It is considered that the holding of the British Empire Exhibition from April to October will materially affect the attendance of overseas buyers, and the change is made so that they can visit both Exhibition and Fair during a single visit. The schedules of trades for the two sections of the Fair are similar to those of last year, London covering mainly the lighter lines of goods, such as pottery, leather goods, stationery and chemicals, whereas the exhibits at Birmingham will include hardware, engineering, metals, power, building and mining implements.—(*Official.*)

Imports of Coal-tar Dyes into British Malaya

Statistics (furnished by the Malay States Information Agency) of the values of imports of coal-tar dyes into British Malaya, showing countries of origin, during 1921, 1922 and the first four months of 1923, are interesting. Although the market for coal-tar dyes in British Malaya is not an important one, the figures are noteworthy as showing from what sources such supplies as are required are forthcoming:—

Imported from:—	1921	1922	1923 (4 months)
	£	£	£
United Kingdom ..	398	454	243
British Possessions ..	770	697	6
Continent of Europe ..	7,771	4,597	6,044
U.S.A.	20	nil	nil
Japan	nil	9	nil
Other Countries ..	1,735	708	181
Total	£10,694	£6,465	£6,474

The value of coal-tar dyes imported from Germany in 1921 was £6195. Separate statistics for Continental countries in 1922 and 1923 are not yet available.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, AUGUST 17, 1923 No. 33

EDITORIAL

IN considering the problem of smoke abatement, it is often forgotten to ask whether a remedy for the evil—and no one will deny that it is an evil, even if sometimes unavoidable—is to be found in prevention of the emission of black smoke or in prevention of air pollution by noxious but invisible fumes. Attention has recently been called to this latter aspect of the question by Mr. C. E. Stromeyer, chief engineer to the Manchester Steam Users' Association, who, writing in the *Manchester Guardian*, pleads that the hydrocarbons and sulphuric acid in coal smoke are not injurious to health and lays all the blame on the content of sulphur dioxide. He further observes that the effect of replacing coal by coke as fuel would be to increase the amount of sulphur dioxide in the atmosphere, with the result that fogs would be "white," not black. The smoke could be washed, but this would be too costly to be economic and the substitution of coal-gas for coal would, he claims, mean doubling the boiler-plant capacity, owing to the loss on converting fuel into gas and the lower temperature of the gas flame compared with that of coal. Whether this aspersion on coal gas could be substantiated can be safely left to the gas industry. Mr. Stromeyer, however, concludes by asking for research on the removal of the sulphur-bearing minerals in coal. Sulphur is a strange element: it is a commercial product manufactured on a large scale, but it has an obnoxious habit of making its presence felt sorely when not wanted, whether in coal-gas, hydrocarbons or iron. Well did "rare" Ben Jonson ask, "What makes the devil so devilish . . . but his being perpetually about the fire, and boiling brimstone and arsenic ?" But sulphur is not the only constituent of coal which requires investigation, for, as Dr. Charles Carpenter insisted so eloquently in his address to the Society at Cambridge, we know a great deal about the products of coal, but have little insight into the constitution of the coal itself. Smoke abatement, considered from this aspect, would seem but one feature of the vast problem of the conservation of our coal resources. One can quote the names of many workers in the field, but the fundamental problems have received attention that seems very limited.

* * *

The conservation of coal constitutes but one aspect of the much greater problem, every day more urgent, of utilising *all* the many sources of energy that are supplied so generously by nature. Timber, petroleum, coal are "wasting assets" so we are told, and our methods of converting heat into energy are far from perfect, but yet only a fraction of the available water power has been harnessed, abundant stores of volcanic heat and energy remain untapped, and, not least, our knowledge of the wonderful mechanisms by which plants build up complex products so economically with the aid of a minimum of external energy is far from being complete, though researches such as those of Irvine and his school on the constitution of cellulose or of Baly on the photosynthesis of carbohydrates are helping to shed light in the prevailing darkness. Sir William Ramsay's suggestion to convert coal-mines into huge gas-retorts has never been tried (although a similar experiment with oil-shale is reported from Australia), but some beginnings have been made. Prince Ginori-Conti is utilising the natural jets of steam at Larderello, in Italy, for the production of both power and borax, and projects are being put forward to make use of natural sources of heat in other parts of the world. It has even been reported in the daily Press that the staff of the Engineering Department of one of the Japanese Universities is about to initiate experiments to test the commercial possibility of producing power from volcanic heat. . . . . We have wandered a long way from smoke abatement, but enough has been said to emphasise once more the need for regarding it as part only of the problem of fuel conservation.

CELTIUM OR HAFNIUM ?

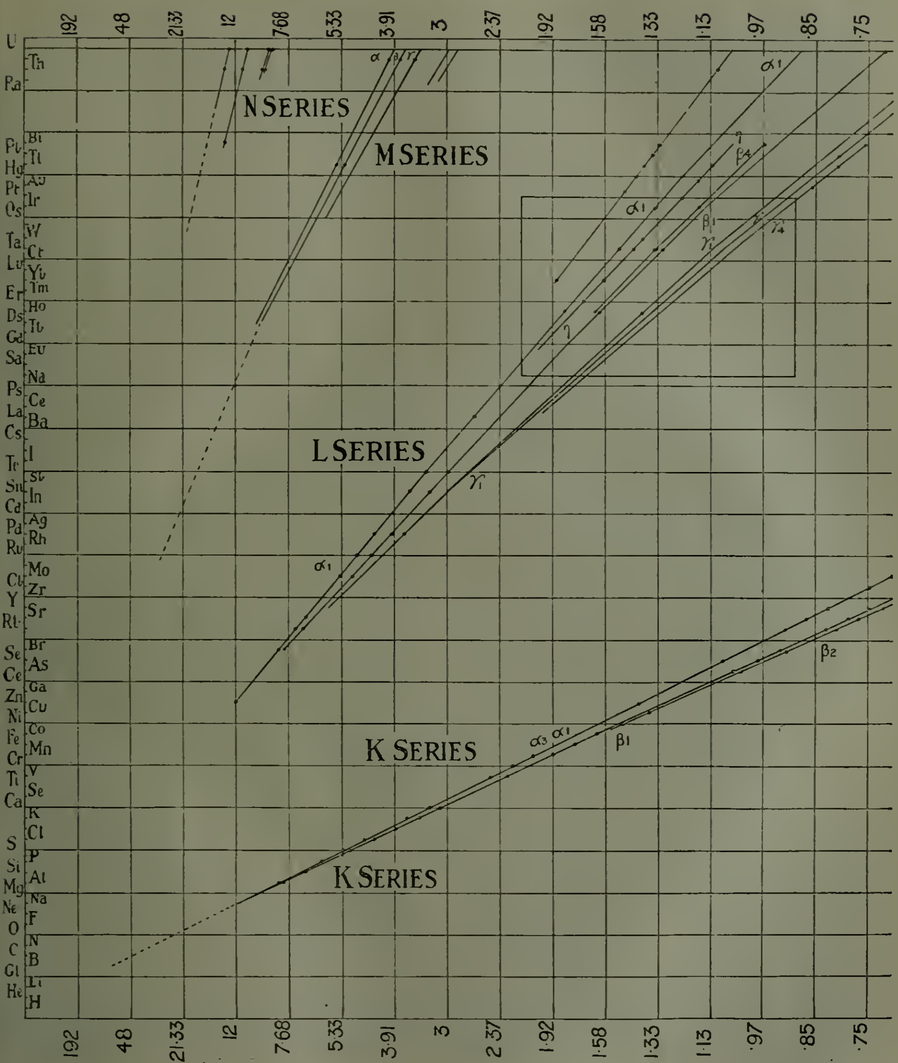
We have received a number of reprints of letters and articles by Profs. Coster and von Hevesy on their discovery of hafnium, an article by Prof. Urbain, the discoverer of celtium, which we published last week, and some other notes on these two names which we have not published. There seems to be some interest in the various claims to the right to christen the element whose atomic number is 72, and in order that our readers may have some of the essential data included in one article instead of scattered about in a variety of journals of different dates we present the following summary :—

In the year 1911, when Prof. Urbain first suggested the name celtium for an element which had prior to that time been neither described nor named, our knowledge of the elements of the rare earths group was less accurate than it is at the present time. It was well known that many elements, possessing obvious features of similarity, existed and that these formed an exceptional group lying between barium and tantalum in the periodic table, but it was not known how many such elements existed nor was it easy to be sure that all the then so-called elements really had elementary characters. In the years from 1896 to 1906 quite a number of new " elements " were suggested which afterwards turned out to be old elements or mixtures of old elements. Among such erroneous new " elements " we may mention lucium, kosmium, neokosium, glaukodymium, the elements Γ, Δ, Ω and Θ of Demarçay, and the incognitum and ionium of Crookes. In the years 1905, 1906 and 1907 two skilful students of this branch of chemistry, namely, Auer von Welsbach and George Urbain, independently investigated compounds of the element ytterbium which was discovered by Marignac in the year 1878 ; each showed that the " ytterbium " of Marignac was a mixture of two elements. Von Welsbach called the two new elements aldebaranium and cassiopeium ; Urbain called them neo-ytterbium and lutecium respectively. A few years afterwards (1911 or 1912) the International Committee for Atomic Weights decided that, notwithstanding some error in his description, Marignac had substantially discovered one of these elements which should retain his name of ytterbium and that the name suggested by Urbain for the other, lutecium, should be officially adopted.

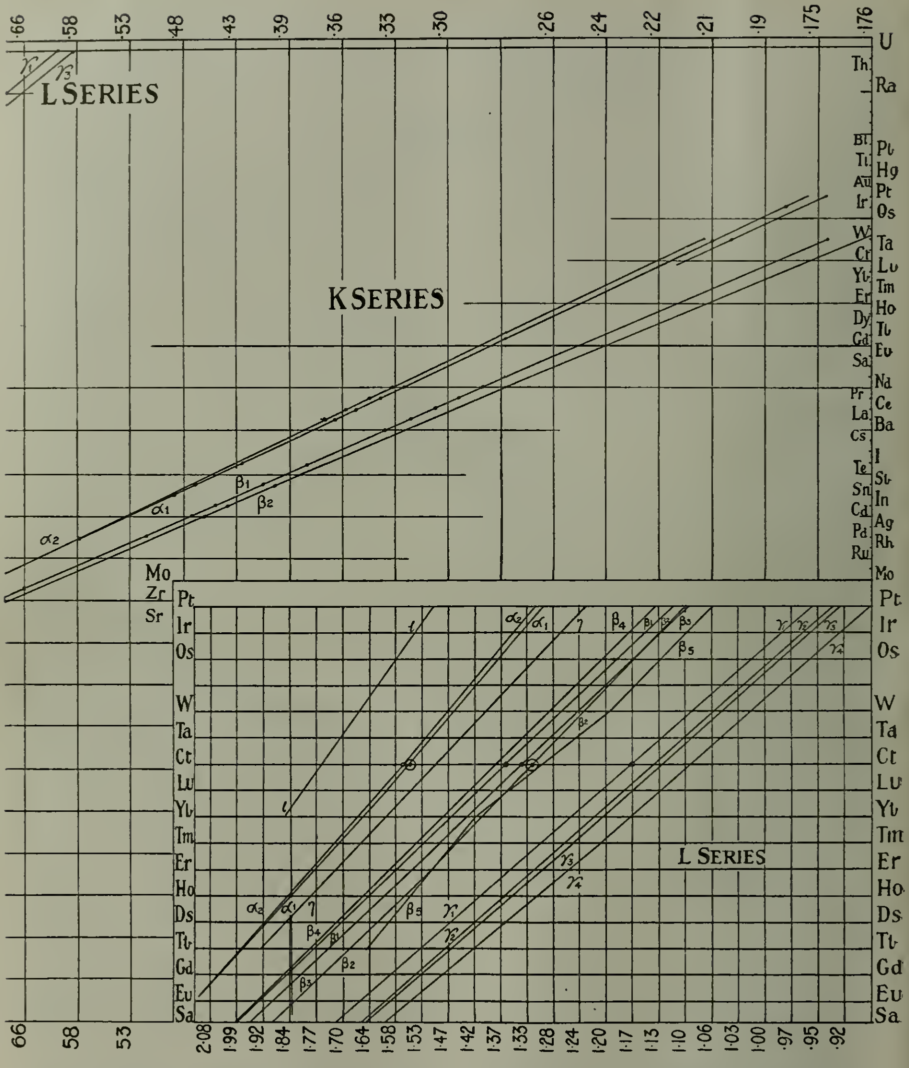
In 1911 Urbain announced that in the mother liquors left after crystallising certain rare earth salts he had found a new element which he called celtium. He described some of its chemical properties and its arc spectrum, giving measurements of some sixteen lines contained in it. As it was derived from a mixture of rare earths of the ytterbium group, he assumed the new element was analogous to lutecium, ytterbium and the other rare earth elements.

In the winter of 1913-14 and the spring of 1914, Moseley published his very remarkable and fundamental work on X-ray spectra of the elements. X-rays were discovered by Röntgen in 1895, and it was noted by Moseley in 1913 that each individual element had its own characteristic X-ray spectrum which could be obtained by allowing the cathode rays to strike solid compounds of the element. Moseley in 1913 proved that the square roots of the frequencies of the lines in these X-ray spectra were approximately proportional to the number of the place in the periodic table occupied by the element in question. From certain other physical considerations it had been suggested independently by Barkla and Van den Broek in 1911 that the elements could be arranged in a consecutive order of " atomic numbers " which would denote the true place of the element in their sequence ; the work of Moseley enabled these atomic numbers to be determined accurately. It was soon ascertained that the element erbium was No. 68 and that tantalum was No. 73, but the accurate measurement of the X-ray spectra of the intermediate elements took some time to effect. The elements supposed to fill these places were thulium, ytterbium, lutecium and the newly discovered element, celtium. At first different authors filled in these four spaces, either partially or wholly according to their individual tastes ; and as most of the rare earth elements are known to be tervalent and as tantalum is quinquevalent, the one, or perhaps more than one, element preceding tantalum must be quadrivalent. Rydberg and Brauner each had his own plan, and Benedicks, Meyer and others put forth various suggestions, but by the year 1917, at any rate, it seemed to several who had studied the subject that the four elements existing between erbium and tantalum were thulium, ytterbium, lutecium and celtium in the order given. If this idea were accepted, it followed that celtium must be quadrivalent as suggested by Rydberg, Brauner, Benedicks and others in what seem to us now rather confused and difficult terms.

The X-ray spectra of thulium, ytterbium and lutecium were all measured with considerable accuracy before the year 1922, and it must have been obvious to anyone who was familiar with Moseley's work that if celtium occupied the position No. 72 immediately preceding tantalum, it was a quadrivalent element. The chief point of doubt—say in 1920 or 1921—was whether the existence of celtium was proved or not ; when the X-ray spectra of thulium, ytterbium and lutecium became known, it was equally known that the element 72 was either celtium or an element so far not discovered and that it was a quadrivalent element. It is no easy matter to search through back numbers of the *Comptes*



Rendus and the *Philosophical Magazine* and keep in touch with the complex tables which replace the once simple diagrams which illustrate the law of Moseley. The large diagram given above shows the general law, the vertical distances showing the elements in due order. The horizontal distances are proportional to the squares of the frequencies, but have been marked out in wave-lengths for greater convenience in plotting. The small diagram shows on an enlarged scale a portion of the L-series of spectra of some of the rare earth and neighbouring elements; no attempt has been made to show all the lines. It is clear from these diagrams that for short lengths the various lines are so nearly straight that if the spectral lines of adjacent elements on each side are known the wave-lengths of the middle element



can be predicted with considerable accuracy and conversely, if new lines are found, the place of the element to which they belong can be predicted with equal accuracy. The publication in 1922 of de Broglie's book on X-rays provided in a convenient form a mass of information which was previously unobtainable otherwise than by long search by someone thoroughly familiar with the subject.

We will now consider the X-ray spectrum of celtium and see how this affects the problem. Urbain tells us that he preserved a small quantity of his original 1911 mother liquor and visited Moseley at Oxford in July, 1914. Moseley obtained an X-ray spectrum which showed only about 10 lines which were attributed to lutecium and ytterbium. Both Moseley and Urbain were in a short space of time mobilised. Moseley was, unhappily for science, killed in Gallipoli in 1916. Urbain fortunately is still able to pursue his favourite study. After the war Prof. Urbain visited de Broglie, taking with him the original 1911 material and asked for a new X-ray spectrum with all the refinements and additional accuracy which the improvements effected since 1914 had made possible. M. de Broglie persuaded his collaborator M. Dauvillier to make the experiment, and the spectrum so obtained shows two lines with wave-lengths 1319·4 and 1561·8. A reference to the smaller of the diagrams shows that the line 1561 might either be an α line of element 72, a β line of erbium or of holmium or even a γ line of europium. The line 1319 might be either a β line of element 72 or a γ line of erbium. If erbium were present the spectrum should show the most persistent of the α and β lines of erbium, which according to Dauvillier it did not. The same is true of holmium. M. Dauvillier therefore attributed these two lines to the element 72, and as Urbain said the sample contained celtium, the obvious and true inference was that celtium was element 72. An account of this work was published by Dauvillier in the *Comptes Rendus* of 1922 and summarised by de Broglie in his book on X-rays published the same year (pp. 110, 111). In January, 1923, Messrs. Coster and von Hevesy announced that they had discovered a new element called hafnium which occupied the 72nd place in the list of elements and had an X-ray spectrum containing lines α_1=1565, α_2=1576, β_1 1371, β_2 1323, β_3 1350 and γ_1=1177 X units. (See *Chem. and Ind.*, 1923, p. 67.) These lines are shown by a dot on the small diagram, those already detected by Dauvillier being marked by a small circle. These values differ by some few units from the earlier measurements by Dauvillier, and further experiments made by Urbain and Dauvillier this year yielded the presumably more accurate values, β_2 1322 and α_1 1564.

Now if Messrs. Coster and von Hevesy claim the right of naming element No. 72 by reason of priority it seems in the circumstances they ought to prove that Urbain's celtium does not exist, or does not occupy the place 72 in the periodic table. Instead of this, it seems to us they have proved (1) that the element No. 72 (whether called hafnium or celtium) is quadrivalent and not tervalent as originally supposed by Urbain and (2) that the optical spectrum originally attributed by Urbain to celtium really belongs to lutecium.

(1) Messrs. Coster and von Hevesy state in their letter of March 20, 1923, to *Nature*, that it was the theoretical conclusion of Bohr (see his *Theory of Spectra and Atomic Constitution*) which led to the anticipation that the element 72 should be a homologue of zirconium. Prof. Urbain thinks the credit for treating celtium as an analogue of zirconium is due to Bury or Perrin in 1921. But we are not sure, with great respect to Prof. Urbain, Coster and von Hevesy that this suggestion is not prior to Bohr, Bury and Perrin. Since the time of Mendeleef or possibly earlier it has been assumed, in accordance with a law to which there seems to be no exception, that the valency of an element is increased by one unit over the valency of the preceding element if there is any increase at all. So that if lutecium is tervalent and tantalum is quinquevalent it is reasonable to suppose the intermediate element is quadrivalent. What has been in doubt is not whether the element No. 72 is quadrivalent, but whether possibly elements 71 and 70 and some others also may be quadrivalent and this really is the problem discussed by Rydberg, Hicks, Brauner, Biltz, Meyer, Benedicks and others. Celtium had been provisionally assigned to the 72nd place in the list of elements at least as early as the year 1917 (at any rate) and we think that any one who in the years 1918, 1919, or 1920 tried to construct a periodic table, which included celtium in it, would have been obliged to take note of the law of Moseley and put celtium in the place immediately preceding tantalum, which means placing it in the same series as zirconium and thorium. In publications by Little in 1917, by Caven in 1917, by Darwin in 1920, by H. E. Armstrong in 1922, and doubtless many others during the few years prior to 1922, either celtium or the last of the rare earths was indicated, sometimes more or less provisionally, as occupying the place 72 in the list and forming part of the series which includes zirconium and thorium.

(2) Prof. Urbain agrees that the lines in the optical spectrum which he thought belonged to celtium really belong to lutecium. There is no dispute about this.

Now let us review the whole situation. In 1911, Urbain came to the conclusion that a certain substance contained a new element which he called celtium. His reasons were (1) faint chemical and magnetic observations which carry no conviction, (2) an optical spectrum containing a number of hitherto unknown lines.

In 1911, 1912, 1913, and 1914 the work of Barkla, Van den Broek, Moseley and others led to a list of atomic numbers, which show that an element of atomic number 72 must be added to the list of those which were already accepted; this element must come between lutecium and tantalum and unless it is quadrivalent it is the one exception to the law which has been noticed as to valency. A number of writers between 1914 and 1922 assume with very little proof that Urbain's "celtium" is the element in question, place it in the space No. 72 and either say nothing about its valency or put it in the list of the zirconium-thorium group, because space No. 72 comes there and nowhere else.

In 1922, Urbain has his original material more carefully examined both by X-rays and the ordinary spectroscope. The X-rays show that his material contains a proportion of element 72, the ordinary spectroscope shows that the unknown lines really belong to lutecium. Urbain and those who made these experiments retain the name "celtium" for the element. A few months later Messrs. Coster and von Hevesy, searching for the new element in a fresh direction, find it in considerable quantity and make a careful investigation of some of its properties by methods and to a degree hitherto believed to be impossible.

Any ordinary man would draw from these facts the following conclusions. Urbain stated that in 1911 a certain material contained a new element. He gave a number of reasons at that time in support of his statement. As time went on all his original reasons turned out to be mistaken or without foundation, but his statement was true nevertheless and before he had shown all his original evidence to be worthless he, with the assistance of M. de Broglie and M. Dauvillier, had obtained one important piece of new evidence, which proves the truth of his statement.

The fact that Urbain thought in 1911 the element celtium to be more allied to ytterbium than to zirconium seems to be of little importance. It was not until 1914 that one could say what places in the periodic table all new elements ought to occupy and not until the X-ray spectra of ytterbium and lutecium had been measured that the position of the element in question could be fixed with certainty.

The question of priority might have been much more difficult had some third party shown, say, in 1913 or 1914, that the new spectra found by Urbain really belonged to lutecium. Urbain would then very likely have acknowledged that his new element was as mythical as kosmium or incognitum and it would have been difficult for him to re-establish its genuineness. Fortunately for him, no one seems to have shaken the credit of his new element until it was too late and he was able to supply it with the necessary authenticity before he himself withdrew certain of his earlier reasons for believing in its existence. We are inclined to think that Prof. Urbain discovered celtium rather luckily in 1911, but that his claim to be discoverer would have been very unsubstantial had he not, with the assistance of Dauvillier, provided a firm foundation for it by identifying its X-ray spectrum in the spring of 1922. Both the work of Urbain on the rare earths and the work of Coster and von Hevesy are of first-rate importance and every student of accurate X-ray work knows how much we are indebted to Coster, Hjalmar, Dauvillier, de Broglie and the others who have placed this subject on the high level of accuracy it has now reached.

It is a little singular how highly specialised the study of the elements in this particular region of the periodic classification remained until the researches of Moseley, Rutherford, Bohr, Langmuir, Lewis, Dauvillier, Somerfeld, Kossel and some others showed how closely all the elements are related constitutionally. In pursuing the history of celtium we find that in pre-war days many of those who studied the rare earths had no particular interest in X-ray methods, whilst the men who studied X-rays had no time for ordinary spectroscopy or the electronic theory of valency. We cannot conceive any dispute as to the family of elements to which No. 43, No. 61, No. 75, No. 85, and No. 87 respectively belong, and we think no one who was acquainted with the great progress made in the years 1914, 1915, and 1916 could have really disputed the relationship of No. 72 at any time after, say, 1916 if he had for a moment stopped to consider the meaning of the work which had been published up to date. We do not know what decision the International Committee on the Elements will announce, but we think that Urbain and Dauvillier are quite justified in attaching the name "celtium" to No. 72 until reasons far more disingenuous than any yet adduced are advanced to prove that they did not discover the existence of this element.

HYDROGENATION FLAVOUR

By KAPIBRAM H. VAKIL, M.Sc.Tech., B.A.

Hydrogenation of oils and fats has assumed such considerable importance that there exists an ever-growing volume of literature on this branch of applied chemistry, covering almost every aspect of the process, but it seems that on one point, viz., "hydrogenation flavour," most of the observers are silent; though there are certain references on this subject in recent publications many of them are very vague.

The use of hydrogenated oils for edible purposes, specially in confectionery, in biscuit manufacture, and in the preparation of butter and ghee substitutes and other milk products[1] such as compound milk will depend largely on the removal of this process flavour from hydrogenated oils and fats. Though hydrogenated oils are largely used in the United States in the preparation of vegetable shortening and lard substitutes, the difficulty regarding the removal of the hydrogenated flavour does not seem to have been completely solved.

The development of hydrogenation flavour is not noticeable in small-scale laboratory experiments under varying conditions, and particularly when the gas is not returned to the autoclave or flask, the product obtained does not exhibit the characteristic hydrogenation flavour. But on the application of the process on a larger works scale, when for economical reasons the gas is used over again or totally absorbed, the resulting product is entirely different from that obtained in the laboratory and shows a marked characteristic odour which is not confined to any particular class of oil nor does it result from the very small quantity of impurities which is usually present in neutral refined oils. Even highly purified and deodorised oils give rise to this hydrogenation flavour.* A variation of the four important factors which control the process of hydrogenation, viz., time, temperature, pressure, and agitation, does not in any way materially lower the development of the process flavour, indicating that the flavour does not originate in any selective hydrogenation of the different glycerides.

The origin of the flavour must, therefore, be traced to the formation of certain volatile bodies during the process. These volatile substances in the laboratory experiments are removed with the gas as they are formed and have no chance of flavouring the final product, whereas in works practice, as the gas is used over again till completely absorbed, these volatile substances remain in the oil and give rise to the peculiar odour.

This particular feature of the process of hydrogenation does not seem to have been systematically dealt with by the observers, though Wilbuschewitsch[2] tries to overcome this inherent defect in the process by passing the circulating hydrogen through caustic soda solution. Fahrion[3] also suggests the use of alkaline solutions for the purification of the excess gas.

During hydrogenation on a large scale water is formed. Lush[4] regards this formation as due to the further reduction of nickel oxide or sub-oxide. This water is removed by cooling the circulating gases coming out of the converter and before they are sent back into the process. The condensates thus obtained are very strongly odoriferous, even though a considerable amount of the volatile odoriferous substances pass on uncondensed with the gas. To strip the hydrogen completely of these odoriferous substances effective scrubbing with caustic soda or similar substances is necessary. A solution of 10 per cent. ferrous sulphate was successfully used as a scrubbing agent in a centrifugal scrubber. The odour is not very apparent in a warm sample taken out from the filter press, but after cooling and standing, the flavour becomes distinctly pronounced. The use of a purified gas, therefore, does not give such a completely odourless substance as is obtained on a laboratory scale. For this reason a further treatment of the material after hydrogenation seems necessary.

It is now the general practice to remove this flavour by superheated steam, and in certain American plants provision for the steam deodorisation of hardened oil is a distinct feature of the lay-out. The use of superheated steam for deodorisation does not seem to have given completely satisfactory results, as is evidenced by the pronounced hydrogenation flavour in many of the American brands of vegetable shortening. Many of the workers had, therefore, to resort to a further treatment[5] with whole or skimmed milk, butter milk, or sour milk.

Scrubbing of gases in the process, vacuum steam deodorisation and a treatment with milk and similar substances have not yet satisfactorily solved the problem, as the hydrogenated product still requires various flavouring substances, such as cumarin, vanilla, orange or lemon oils, butyric acid or various esters of lower fatty acids. It is generally noted that however carefully a steam deodorised hydrogenated product is prepared and stocked the characteristic flavour reverts in a comparatively short time. Samples of American vegetable shortening and lard substitutes invariably develop in course of time the hydrogenation flavour. It is on this account that the use of hydrogenated oils is not preferred in biscuit manufacture. A well-known British firm of biscuit makers very nearly ruined its business on account of the development of hydrogenation flavour in its biscuits. An interesting feature is that the hydrogenation flavour does not easily blend with other flavouring substances and cannot therefore be completely masked by them.

Joslin[6] suggests the treatment of the hydrogenated oils with alcohol and a further purification by means of steam or an inert gas. It is found, however, that treatment with carbon dioxide or a mixture of carbon dioxide and nitrogen, between 145° and 150° C., under normal pressure for 45 to 50 minutes, completely removes the hydrogenated flavour. Samples treated by this method have on long standing shown no signs of reappearance of the odour as is noticeable in steam deodorisation.

It seems natural to conclude that the hydrogenation flavour originates in the formation of a volatile product. In the absence of any systematic research work on this subject it would be premature to hazard any opinion as regards the composition and properties of the odoriferous substance, though it is regarded by some authorities as of aldehydic or ketonic character. It may be due to polymerisation of the oil at high temperatures used in the process, and or to the breaking up of certain triglycerides into di- or mono-glycerides and their reduction into aldehydes or ketones. The fact that most carefully refined and deodorised neutral oils give rise to this hydrogenation flavour indicates that the origin of the flavour must be traced not to any foreign substances occurring as impurities in oils but to the formation of an intermediate product in the process itself.

---

* Fahrion[3] has described the hydrogenation flavour, "Härtungsgeruch," of different oils.

THE WORKS OF GEBER

By Prof. J. R. PARTINGTON, M.B.E., D.Sc.

A recent issue (1923, 42, 502) of this *Journal* gives an abstract of a reply by Prof. E. O. von Lippmann (*Chem. Z.*, 1923, 47, 321) to a letter of mine on the subject of Geber. Since no account of my original arguments, published in *Nature* (1923, **111**, 219), nor of my reply (*Chem. Z.*, 1923, 47, 429) to Prof. Lippmann's article, has appeared in this journal, it seems reasonable that I should have an opportunity of examining the observations of Prof. Lippmann to which attention was directed. In my first letter to *Nature* I gave (as far as I am aware for the first time) an analysis of the arguments used by Berthelot against the identity of the author of the Latin works attributed to Geber with the Arabic writer Jabir ibn Hayyan, to whom they were formerly attributed. I suggested that Berthelot's arguments were unsound, with one possible exception, viz., the alleged difference between the translation and one which could have been made from Arabic. Prof. E. Wiedemann, of Erlangen, has been good enough to express an opinion, in a letter to me, which appears to support this view. Because of this, and also of the contents of the translations of the Arabic writings of Jabir ibn Hayyan, to which I referred in the *Chemiker Zeitung*, I suggested that the original author of the Latin works *may* not have been Arabian. In a note at the end of my letter to the *Chemiker Zeitung* (p. 429) Prof. Lippmann again assumes the contrary, in spite of the definite statement in my letter, and he adds the following remark : " The question what views *Berthelot* has entertained is a matter of secondary importance and can lead *alone* to no decision. *My* position is based on the *whole* of the facts known to me, and cannot be designated as resting on prejudice." (Emphasis as in original.) In his first article he also stated that the account of the matter given in his " Alchemie " leads necessarily, step by step, to the conclusion first reached by Berthelot. It now seems necessary to examine Prof. Lippmann's account. In the first place, it is evident that he has made use of only a limited amount of the available information, as a glance at the literature quoted by Ferguson (" Bibliotheca chemica," vol. 1, pp. 302–4) will show. In the second place, even this limited field has not been very accurately covered.

The short section (pp. 485–488) devoted to the subject by Lippmann begins by quoting the opinion of Stahl (" Gedancken und Bedencken von dem so genannten Sulphure," Halle, 1718, p. 48 : quoted as " Vom Sulphure " by Lippmann), who merely remarks that Geber could hardly have been a " King of Arabia," since he would have had no subjects, but does not, as far as I can see, throw any doubt on the authenticity of the *writings* of Geber, as Lippmann says he does. The latter next quotes a statement of Reiske's, through the medium of a later work, *i.e.*, at third hand. In the original work of Reiske, a note in the edition of the " Annales moslemici " of Abulfeda, Copenhagen, 1790, vol. 2, p. 629, the editor quotes another " opinion, that the name may be fictitious, invented by the alchemists," and refers to d'Herbelot's " Bibliothèque orientale," Paris, 1697, p. 387, where Geber is said to have written a large number of works on the philosopher's stone. " Our chemists, who have never read these books, nevertheless make a great noise about them in their works." He is here referring, I imagine, to the works of Jabir ibn Hayyan, the authenticity of which is admitted. The remarks of Beckmann, to which Prof. Lippmann refers, are not concerned with the " Sum of Perfection " of Geber ; those of Sprengel are not supported by any reasoning. Davy is next said to have regarded the works of Geber as " compilations of the alchemists of the 15th and 16th centuries," but he is referring to the MSS. of these dates in the British Museum, which are late copies. In the " Geschichte der Botanik " of E. Meyer (vol. 3, p. 98, 1856), who relies on Reiske to some extent, it is said that it " is just possible that neither G'abir nor Chalid Ben Jazid ever lived or wrote " (the quotation given by Lippmann does not occur), but he is referring to Jabir ibn Hayyan. As to the opinion of Latz (in his confused and superstitious book, " Die Alchemie," Bonn, 1869, p. 438), it is sufficient to say that he refers to " Kallid," and that Prof. Lippmann has substituted " Geber " in the quotation which he gives in parentheses ! When it is added that Latz believed in alchemy and that he interpreted Genesis in an alchemical sense, his value as an historical authority may be questioned, and when he is misquoted it is still further diminished. We are next told by Prof. Lippmann that Steinschneider held Geber to be " an almost mythical person," and remarked that the knowledge referred to him does not occur in the works of Jabir. Steinschneider is referring to Jabir ibn Hayyan, and merely remarks that a book on poisons attributed to Jabir does not occur in Borel's "Bibliotheca chemica" ("Hamburg, 1656, 97"; in my edition, Paris, 1654, p. 102, the works of *Geber* are given). Steinschneider does not seem to have separated Geber and Jabir. Prof. Lippmann now states, as he has done on several occasions, that the remark of Steinschneider led Kopp to revise his views on Geber, that in doing so he practically arrived at the view expressed by Berthelot, and that the latter merely added the last link in the chain, "if, in view of the above statement, this was really necessary." Kopp's conclusion was that "with reserve I can still regard these works as Geber's and assume that they are translated from the Arabic" (Beiträge, vol. 3, p. 33). Kopp's investigation, although valuable, is based on three late printed texts of Geber and otherwise largely on library catalogues, not on manuscripts. They are summarised by Prof. Lippmann on p. 486 of his "Alchemie," and amount to the observation that the accounts of Geber (Jabir) given by Oriental writers are confused (as was pointed out at least as early as 1851 by Hammer-Purgstall, "Litteraturgeschichte der Araber," vol. 2, p. 185; vol. 3, 1852, p. 299), and that the style of the Latin works, which are not known or mentioned before 1300, is "scholastic." I have dealt with the last point; I cannot express an opinion on the Arabic accounts. Prof. Lippmann has not thought it necessary to do much more than refer to his "Alchemie" as a criticism of my arguments. I must again assert, and I hope the reason will now be quite clear, that I regard that account as untrustworthy, and that, as far as I can see, the views which I expressed as to the validity of the arguments based on the *internal* evidence of the Latin works have not yet been satisfactorily dealt with.

Since the above was written I have read the brief article of Prof. Darmstaedter, of Munich, in the *Chemiker Zeitung* of July 21, in which he refers to my previous letters—unfortunately only through the medium of Prof. Lippmann's article. For the latter reason, probably, Prof. Darmstaedter attributes to me opinions which I have not published. Prof. Darmstaedter's remarks are otherwise very interesting and instructive, and I can only hope that he will make himself acquainted with my original communications. I may add that I intend shortly to publish elsewhere some account of the Latin writings of Geber, since much confusion appears still to exist on the matter; some of the statements of Prof. Darmstaedter, for example, in the introduction to his recent book on the alchemy of Geber, are far from correct. Some of these he has himself corrected in the article to which reference has been made.

BRITISH CHEMICAL PLANT MANUFACTURERS' ASSOCIATION

The third annual general meeting was held on July 18, Mr. L. M. G. Fraser in the chair. The chairman, in moving the adoption of the annual report, said that the membership kept roughly constant and the financial position was increasingly sound; the Association started with a balance of £177 and the carry-forward to next year was £264. Mr. Fraser then discussed methods of improving the usefulness of the Association, and he suggested that members should be invited to participate in the work of theoretical and research bodies, on which their engineering knowledge would help. Referring to the work carried out on standardisation of jacketed pans and of filter presses, the chairman said that the Association had altered their patterns and incurred expenses for the ultimate advantage of chemical manufacturers, and they had hoped that their advances would have been better appreciated. The subject had again been brought to the notice of the Association of British Chemical Manufacturers. After referring to the favourable result of the collective exhibit at the British Industries Fair, 1923, it was stated that sufficient support could not be obtained to have a section at the British Empire Exhibition. The suggestion was made that the Association should be represented on the Cast Iron Research Association, and the importance of research on corrosion was emphasised. Other points dealt with were education, under which attention was called to the doubt as to the true meaning of the term "chemical engineer"; standardisation of chemical plant; and the reductions, etc., in rail rates. The report was unanimously adopted, and Mr. L. M. G. Fraser, Mr. F. R. Blizzard and Mr. E. A. Alliott were re-elected as chairman, vice-chairman and honorary treasurer for the forthcoming year, Messrs. H. Bush, J. H. Rawson, R. Seligman, E. C. Watkins and J. W. Wright being elected members of the executive committee. It was agreed that a scheme should be prepared for the issue of a calendar for the year 1924 to give information on plant produced by the members of the Association.

ACADÉMIE DES SCIENCES

During the meeting on August 6, Monsieur D. Berthelot communicated a note on the "Control of the Action of Fertilisers," by M. Blaringhem, who showed that more accurate results than those obtained by comparing the increase in weight of the crop on manured as against unmanured plots could be furnished by applying methods of experimental genetics to pure lines with constant somatic characters. Thus, using Howano flax, the leaf density of 11 for the controlled plots became uniformly 16 for plots manured with potash and 21 for those manured with nitrogen; similar results being also obtained with cereals. The method makes it possible to trace the influence of fertilisers at all periods of the life of the plant.

At a previous meeting, Prof. Moureu communicated a note by Professor H. E. Armstrong on "The Origin of Osmotic Effects: Hydronodynamic Transformations in Aqueous Solutions." Prof. Moureu also communicated a paper by MM. Helbronner and G. Bernstein, who showed that, in presence of a small amount of a reducing agent, rubber is protected from the action of oxygen both at ordinary temperatures and at the temperature of vulcanisation, the result recalling the work of MM. Moureu and Dufraisse on "Anti-oxygènes," a subject to which MM. A. Gillet and Fernand have devoted some attention in relation to the action of copper salts on dyestuffs. Prof. Perrin described the results obtained by M. Marcellin on the "Measurement of Variations of Surface Tension with the help of traces of Oleic Acid," and announced that M. Holweg had devised a new molecular pump.

CORRESPONDENCE

YOUR PENCIL UNMASKED

Sir,—Like many other old members of the Society, I have followed with interest your efforts to make our publications known to a wider circle of readers, and I now observe that you are striking a distinctly new note in publishing as an article in *Chemistry and Industry* a *resumé* of a paper which was published in the Transactions.

In November, 1919, my communication on "Pencil Pigments and their Examination in Writing" appeared in the Transactions, and in *Chemistry and Industry* for July 20 (p. 710) there is published an article with the title "Your Pencil Unmasked," by Mr. F. Colin Sutton, in which my original work has apparently been summarised, although the writer of the article has missed the opportunity of letting it be known that he was referring to an investigation already published by the Society, and has thus deprived another section of the journal of the publicity to which it is entitled.

Or have two chemists studied the characteristics of pencil writing and, by a curious coincidence, used for the purpose the same MSS. in the British Museum? If so, I should be glad to have the name of this anonymous authority, with whom I have so much in common.

If, however, it is my work only which has been adopted, without acknowledgment, for the purpose of this article, a story which is told of Virgil seems apposite. Virgil (if I am mistaken as to my poet your classical contributors will forgive me) had had some of his poems claimed by someone else. As a test he wrote some unfinished verses, and when the other man could not complete them, Virgil added the missing portions, and concluded with the words: "*Hos ego versiculos feci, tulit alter honores.*"

Possibly the exigencies of metre prevented the use of the word "honoraria" for "honores," or it may be that in those days poets, like the authors of scientific papers to-day, had to be content with the credit for the work—when they could get it.—I am, Sir, etc.,

C. Ainsworth Mitchell

CELTIUM

Sir,—In the article "Chemistry," in the current supplement of the *Encyclopædia Britannica*, published, I believe, early in the summer of last year, a table of the elements is given in which these are arranged in the order of the Moseley series numbers and also in homologous series. Celtium is placed at 72 in the zirconium and titanium column. I therefore am to be reckoned among those who placed Prof. Urbain's discovery properly in advance of Messrs. Coster and Hevesy. The article was sent to press about a year before it was published and I never saw a proof. I believe it was printed in America. I was only guided by what I had read and well recollect hesitating to assign an element found in rare earth material to another series—but there was no other place for 72 in my scheme, which I venture to think is the most rational periodic arrangement of the elements yet put forward.—I am, Sir, etc., Henry E. Armstrong

Granville Park,
Lewisham, S.E. 13

THE BRITISH PHOTOGRAPHIC RESEARCH ASSOCIATION

Sir,—You will be pleased to know that since my letter in your issue of July 13, the Department of Scientific and Industrial Research and the photographic manufacturers have been able to arrange a scheme by which the British Photographic Research Association is assured of a further existence of four years. It is also expected that as a further result of this it will be possible to place the Association on a practically permanent basis.—I am, Sir, etc.,

Ilford B. V. Storr
Aug. 13, 1923

PERSONALIA

The Master and Fellows of Gonville and Caius College have elected Mr. W. I. Jones, B.Sc., to a Rhondda Research Studentship for research in organic chemistry.

J. A. Gunton has accepted the professorship of chemistry in the University of Western Ontario.

The following awards for the year 1923-4 have been made by the Salters' Institute of Industrial Chemistry, and approved by the Court of the Company. Fellowships are awarded to Mr. T. B. Philip, B.Sc., Imperial College of Science and Technology, Mr. W. G. Sedgwick, M.Sc., Armstrong College, Newcastle-on-Tyne, Mr. D. T. A. Townend, B.Sc., Imperial College of Science and Technology. Fellowships are renewed to Mr. C. G. Harris, B.A., Jesus College, Oxford, and to Mr. J. H. Oliver, B.Sc., Imperial College of Science and Technology. Mr. W. Randerson, a Fellow for 1922-3, having been elected to an Albert Khan Travelling Fellowship for the year 1923-4 is made an Honorary Fellow for the year.

* * *

Dr. L. Bell, a pioneer in the field of illuminating engineering and power transmission, and the author of numerous articles on photometry, electric motors, etc., died recently in the United States at the age of fifty-nine.

From France the death is announced of Monsieur L. Wolf, vice-president of the Cie des Produits Chimiques et Electro-métallurgiques d'Alais et de la Camarque.

NEWS AND NOTES

UNITED STATES

Chromite in 1921

The U.S. Geological Survey reports that the total sale of domestic ore in 1921 was 282 long tons, equivalent to 245 long t. of 50 per cent. ore. Although this quantity is trifling as compared with that sold during the war, it is close to the average annual production from 1900 to 1913, inclusive, which was 232 tons. Of the quantity sold in 1921 68 long t. came from California and 214 long t. from Oregon. In spite of the large imports in 1920 and the large reserve accumulated, imports in 1921 were remarkably high, amounting to 81,836 long. t., the result doubtless of the low prices, the average price, $8, being even less than the average of $9·56 in 1913. It is thought that a large reserve supply is available, perhaps enough for more than a year's consumption. The imports were derived chiefly from British South Africa, 23,318 t.; Canada, 7554 t.; French Oceania, 35,108 t.; Greece, 8104 t.; and Turkey in Asia, 5822 t. The imports of chromium compounds were small as compared with the consumption. The apparent consumption of chromite during 1921 was 82,118 long t., which compares with 152,777 long t. in 1920. Sales of ferrochrome in 1919 and 1920, the only years for which figures are available, were estimated at 15,763 long t. in 1919 and 16,606 long t. in 1920. The quantity of 50 per cent. chromite required to yield this amount of ferrochrome, on the arbitrary assumption of no loss of chromium in slag, would be 31,700 long t. for 1919 and 33,400 long t. for 1920. The world's output of chromite in 1920 is estimated to have been 190,000 m.t.

FRANCE

Petroleum Exploration

The geological section of the Scientific Petroleum Commission has been requested to draw up a programme of exploration for France and the Colonies. The main outlines of this programme are as follows:—

Prof. Glangeaud will select sites for new borings in Auvergne; apparently in Limagne (where results have already been obtained), the work will be given to the Société Pechelbronn and carried out immediately. A commission, consisting of MM. Viennot-Barabé and Dubar will examine the geology of the Pyrenees, Landes and Gers to determine suitable spots for borings, and another commission will examine the district of Gard and Hérault. In addition, a geological and economic commission will investigate the petroleum deposits in Madagascar, where there are signs of the existence of important deposits of petroleum: the work will be carried out over an area of 1400 to 1500 hectares in the Manche and Cabrados regions.

The Gas Industry

By the Law of July 22, 1923, gas undertakings in France are permitted to supply gas of a lower calorific value than heretofore, so that they can recover valuable by-products such as benzol, a practice hitherto illegal. According to the Law, the minimum calorific value cannot exceed 4500 calories per cubic metre of dry gas, measured at 0° C. and a pressure of 760 mm., nor be less than 3500 calories. However, under certain circumstances, such as the nature of existing plant or the neighbourhood of coke ovens, the calorific value can be varied between 3000 and 4000 calories. A novel feature of the Law is that by joint decree of the Ministers of Commerce and of War any manufacturer supplying gas to the public under permission accorded by the Minister of the Interior can be compelled to extract from the gas the various chemicals or fuels contained in it and necessary to industry or to manufactures of importance to national defence.

Metallurgical Coke

Owing to the importance of the coke problem to France, much interest is being shown in experiments in the manufacture of metallurgical coke from Sarre coal mixed with French lean coal or coal that has been partly distilled or treated in various ways. Important results have already been obtained by the admixture of Sarre dust and lean Auzin coals, as much as 80 and 85 per cent. of Sarre coal being used. The distance of the Sarre basin from sources of lean coal and the fear of interruption in supplies, however, have led to attempts to use native fat coal that has been partially distilled, but so far it has not proved possible to produce semi-distilled coal of sufficiently uniform composition. Further attention has been paid to the system of "progressive carbonisation" introduced by Monsieur Serpy, and designed to distribute the heat as uniformly as possible throughout the coal so as to avoid the excessive cracking that takes place when Sarre coals are heated rapidly. Most of the tests have been carried out at Heinitz, using coke ovens that differ from the usual type only in their relatively small width and in the means for controlling the heat supplied. The oven, at about 600° C., is first charged with a damp "cake" that fills only half the space and cools the walls sufficiently to prevent too rapid heating. After 30 hours the "cake" is pushed back into the oven and replaced by a further half charge. Afterwards coking and degasification take place at the usual temperature. A battery of three ovens of this type has been worked in the Sarre for six months and has yielded coke of satisfactory quality. The by-products obtained are different from those usually obtained; less gas is produced and instead of benzol, an equivalent quantity of a lighter product, resembling petrol, is obtained; there is a higher yield of tar, containing less pitch but more heavy oils.

OFFICIAL TRADE INTELLIGENCE

(From the Board of Trade Journal for Aug. 17)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
British West Indies	Glassware, tinware	165
" "	Window and plate glass	166
Chile	Porcelain, earthenware	182
Far East	Tinware, enamel ware	181
Netherlands	Iron and steel tubes	170
Norway	Wrought iron tubes and fittings	171
"	Leather goods	173
"	Galvanised iron plates, corrugated iron	176
South Africa	Leather goods	11755 /E.D./M.C./2
Spain	Rubber goods	179

TARIFF CUSTOMS EXCISE

Federated Malay States.—Government Notification No. 3591, which is published in the Supplement to the Government Gazette of June 15, 1923, states that the Export of Rubber Restriction Enactment, 1923, shall come into force as from June 25, 1923.

Italy.—The *Gazzetta Ufficiale* (Rome) for July 26, contains a Royal Decree-Law, which provides for certain modifications of the Italian customs tariff that was enforced by the Decree of June 9, 1921. Amongst the goods upon which such reductions of duty apply are iron and steel and manufactures thereof, and these reductions are to be applied, until the termination of the respective Conventions, to goods the produce of, and imported into Italy from, countries enjoying most-favoured-nation-treatment in Italy. They are, therefore, applicable to goods manufactured in the United Kingdom and exported thence to Italy.

Poland.—The excise duty on acetic acid has been increased from 3000 to 6000 Polish marks per kg.

ERRATA.—In the issue dated August 10, on p. 773, col. 2 under "France," line 8, for 6,800 tons read 68,000 t., and on p. 776, col. 2, under "Rumania," second paragraph, line 3, for 19, read 1922.

REPORTS

Report on the Economic and Financial Conditions in Switzerland, December, 1922.

By E. C. D. Rawlins, *H.M. Commercial Secretary, Berne. Department of Overseas Trade. Pp.* 75. *H. M. Stationery Office*, 1923. *Price* 2*s.* 6*d.*

The outlook in Switzerland, though still somewhat disturbed, showed in 1922 more promise of return to a normal state than could be seen in 1921 (*cf. J.*, 1922, 573 R). Depreciated currencies in many countries handicap trade with Switzerland, though this point does not affect Great Britain. Amongst other factors, however, which disturbed the financial equilibrium was the referendum on the capital levy, which, although the proposal was defeated, led temporarily to something of a financial panic.

In 1922 commercial treaties were entered into with Spain, Rumania, and Poland. The system of import restrictions due to expire in September, 1922, was extended to June, 1923, but this had very little effect on British imports. Imports into the country in the first nine months of 1922 amounted to 1356 million francs (the Swiss franc rose fairly steadily during the year from 21·70 to 24·48 to the pound sterling) compared with 2296 mill. fr. during the whole of 1921, whilst exports during the period January to September, 1922, amounted to 1250 mill. fr. (1843 mill. fr. in the whole of 1921). An increase was noted in 1922 in the imports of textiles from the United Kingdom. Imports of coal during the first nine months of the year increased from 801,261 tons in 1921 to 887,530 t. in 1922, and of coke from 167,394 t. to 305,728 t. Imports of metals increased largely: iron and manufactures of, from 150,502 t. to 193,373 t.; lead and manufactures of, from 3581 t. to 5868 t.; zinc and manufactures of, from 1388 t. to 2590 t. Imports of nickel and aluminium decreased, especially of the latter. An increase generally in the imports of chemicals and dyes is to be noted: of pharmaceutical and druggists' wares from 2159 t. to 2846 t., chemicals 64,446 t. to 85,112 t., dyes 7089 t. to 7917 t., technical oils and fats 25,769 t. to 34,702 t. Out of a total of 134 t. of dyestuffs imported in the first nine months of the year, Germany supplied 66 t. and Great Britain 52 t. Petroleum imports increased from 9768 t. in 1921 to 14,271 t. in 1922. Exports of minerals and metals show a general increase, as do also chemicals and dyestuffs. The British Empire heads the list of buyers of Swiss goods, but is fourth as a source of imports.

Most of the Swiss industries continued to suffer from acute depression in 1922. The crisis which began in 1920 in the chemical and dye industry has not abated, in fact is somewhat more severe. Many countries have imposed import restrictions to protect home industries which would in any case prove strong competitors to Swiss goods. German competition is also an important factor.

Report on the Economic, Financial and Industrial Conditions of the Netherlands to February, 1923.

By R. V. Laming, *H.M. Commercial Secretary, The Hague. Department of Overseas Trade. Pp.* 68. *H. M. Stationery Office*, 1923. *Price* 2*s.*

In the year under review the position of agriculture, the chief natural resource of the Netherlands (*cf. J.*, 1922, 297 R), was far from flourishing, and the future is not very hopeful. Several beet-sugar factories were closed owing to the grouping of the principal sugar producers in the Central Sugar Co., which has a working agreement with the Co-operative Beet Producers' sugar factories. From January to November, 1922, 174,888 tons of raw sugar was produced, and this year an output of 275,000 t. of sugar is anticipated. Coal was produced in 1922 to the extent of 4,574,000 t., and several new seams were discovered; the output of lignite for the year was 27,000 t. The Boekels mine yielded 27,507 t. of refined salt.

Industry passed through an anxious time, largely owing to competition from countries with depreciated currencies, but there is opposition to the introduction of protection. Imports in 1922 were valued at 2,026,000,000 fl. (the florin varied during the year between 11·28¾ and 11·70¼ to the pound sterling; par=12·10) and exports at 1,221,000,000 fl., Great Britain supplying 323 million fl. of the imports and taking 302 mill. fl. of the exports. The items include minerals and metals and manufactures thereof—imports 362 mill. fl., exports 95 mill. fl.; chemical products, medicines, paints, and colouring materials—imports 49 mill. fl., exports 39 mill. fl.; oils, resin, wax, pitch, tar and by-products and manufactures—imports 90 mill. fl., exports 118 mill. fl.; glass—imports 13 mill. fl., exports 6 mill. fl.; paper—imports 31 mill. fl., exports 34 mill. fl. Great Britain is the chief source of coal, of which there was a total import of 6,216,000 t. in 1922.

It is becoming more apparent that there is a growing tendency for the Dutch to buy in British markets. The reasons are several, but the falling prices of British goods, the steadiness of British deliveries, and a simultaneous upward tendency in quotations from countries with depreciated currencies are chiefly responsible.

Dr. W. v. Oechelhäuser, whose death was announced some time ago, had played a notable part in developing the gas industry, especially in the introduction of vertical retorts. He also developed the first gas engine to utilise blast-furnace gas directly as fuel.

REVIEWS

Supplementary Notes on Gravimetric Analysis for Beginners. *By* W. Lowson. *Pp.* vi+54. *London: Longmans, Green & Co.,* 1923. *Price* 2*s.* 6*d.*

This little book is packed with that wisdom which the student can only acquire, as a rule, from a sympathetic demonstrator or from tedious experience. There is advice on apparatus and methods in general, and in the notes on typical estimations the reasons for various procedures are clearly stated, in refreshing contrast to the rather haughty directions of some of the standard treatises. A section is devoted to occlusion of dissolved substances by precipitates and the avoidance of errors caused by this common phenomenon. It is noticeable that the author, whilst recommending a double dehydration of silica with intervening filtration, instructs the student to dehydrate only by heating on the waterbath—it is generally accepted that a somewhat higher temperature is necessary to render the silica insoluble. Methods of calibrating volumetric apparatus are briefly described (in defiance of the title!) and a table of solubilities of salts, a table of logarithms and a blank page on which the student is expected to record analytical factors calculated by himself round off a book whose value is greater than the price suggests.

P. C. L. Thorne

The Wet Collodion Process. *By* Arthur Payne. *Second edition. Pp.* 128. *Newcastle-upon-Tyne: Mawson and Swan, Ltd.,* 1923. *Price* 3*s.*

The generality of photographers look upon the wet collodion process as appertaining to a bygone day. From 1855 to about 1881 it was almost the only process used either for landscape work or portraiture; the negatives it produced still arouse the wonder and admiration of the present generation of photographers. But the wet collodion process by no means died on the introduction of the modern dry plate; on the contrary, it took on a new lease of life and to-day holds premier place in process work for the production of line and half-tone negatives.

The book under review, the first edition of which was published in 1907, is looked upon by process workers as a standard instruction book. It is practical, written by a practical man. The description of the apparatus used, the preparation of the plates, the sensitising and the general manipulation leave little to be desired, and with a little care and amplification there is no doubt but that the author could make very much more of it than he has done. It is unfortunate that the issue of a second edition was not made the occasion of a thorough revision and amplification, especially on what the author would probably call the theoretical side. Had this been done, there is no reason why the book should not have become not merely a practical instruction book but a thoroughly sound text book.

Chapter 2 on "Elementary Theory" contains no word of theory and is purely descriptive; it might well contain an account of the theoretical basis of the wet collodion process and should certainly give some account of chemical and physical development and their essential difference. It is true that, on page 106, the author says, "The difference between a physical and a chemical developed plate has already been fully explained," and presumably the author believes that explanation to be in the book, but so far the reviewer has failed to find it.

Chapter 5 on "Chemicals and Materials" would have greater value if a little more detail were attempted and some of the descriptive matter deleted. It is difficult to see just what value there is in the information "potassium chromate occurs in the form of yellow crystals, which are stable." Surely a brief indication of the use of the particular substances, their commoner impurities and their solubility would have real practical value.

Chapter 12, on "Colour Sensitive Collodion Plates," is far from being an adequate account of what to-day is an important subject.

The printing of the book is excellent, the illustrations good and clear, and a full index is given, and one feels that if only the practical side were reasonably reinforced by a simple but adequate theoretical treatment, the book would supply that which we at present lack, namely, a really good text book on the wet collodion process. H. W. Greenwood

Shale Oils and Tars and their Products. *By* Dr. W. Scheithauer. *Second edition, revised and enlarged by* H. B. Stocks. *Pp.* vii+283. *London: Scott, Greenwood and Son,* 1923. *Price* 12*s.* 6*d.*

The publication of a second and revised edition of Mr. H. B. Stocks' translation of Dr. Scheithauer's interesting work on Shale Oils, etc., is in itself evidence of the welcome given to the first edition, and in the absence of any other English book dealing with the German shale products there is no doubt that this book fills a gap in our technical literature that has too long been left empty.

It, however, seems a very great pity that a book which should be of value to so many people—especially to-day when the interest in shale and its products is again very much to the fore—should have much of its value detracted from by what can only be a too hasty passage through the press.

It may perhaps serve a useful purpose to refer to and quote some of the passages which should receive attention when another edition is required.

On p. 12 in the table the ash content of Bovey Tracey lignite is stated to be 10·80 per cent. in the material "as mined" and only 6·85 per cent. in "air dried." There is evidently some confusion here, as the figures cannot refer to the same material or they are not given correctly.

On p. 63, Fig. 4, illustrating the Rolle retort, is printed upside down, and as the description is on the next page one has not only to turn back to see to what part of the figure the reference letters apply but has the further bother of reversing the top and bottom of the book.

It is not conducive to pleasant reading to find carbon bi-sulphide and di-sulphide used practically on the same page, and such expressions as "water of decomposition," "conchoid fracture," "centrifugalised" sound harsh to English ears.

The use of the word "aspirators" on page 165, where vacuum filters is evidently meant will not render the book easier for students.

One is also compelled to ask what is meant by the statement on p. 129: "By the aid of pressure distillation, Engler demonstrated the animal origin of petroleum, a perfect lamp oil having been produced from low grade waste materials, such as stearine pitch and *petroleum* residues."

The description of Krämer and Sarnow's melting point method, on p. 249, is not very lucid when one is directed to put 5 grammes of mercury into a glass tube and *then* to seal one end with "gondron" when the authors prescribe exactly the reverse procedure.

It would have also been much more useful if the figures for costs of production and statistics had been brought nearer to the present time. Costs of working over 25 years old have only an historical value. It also seems strange to find no reference made to the amalgamation of the various Scottish shale companies under the title of "Scottish Oils, Ltd."

One trusts that the reviewer will be forgiven for the perhaps rather severe criticism of those points which seem to him to require a little more care, especially as the expert knowledge and wide experience of both author and translator should, with a very slight extra expenditure of time, have enabled them to produce a book free from the defects alluded to, and one which with all these minor errors remains a remarkably useful and generally reliable epitome of a subject on which there is so little published.

W. H. Coleman

Messieurs F. Roy, industrialist, and L. Lindet, member of the "Institut," have been nominated vice-presidents of the Consultative Committee for Arts and Manufactures.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business in the home and export markets remains very restricted. Makers' prices are practically unchanged in spite of the unpromising nature of the outlook. The demand from the textile trades is particularly poor, and in general practically no interest is displayed in forward purchasing.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d.—5s. per carboy d/d. Quiet.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d. - £8 per ton. Comparatively good demand.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Quiet.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d. per lb. Very dull.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 per ton. Remains a very firm market.
Soda Caustic 76%	£19—£21 10s. according to quality. Fair business.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton. Very scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19-£20 10s. per ton according to quantity, f.o.b London, 1-cwt iron drums included.
Sod. Chlorate	2⅞d.—3d. per lb. Very dull.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Rather lower in value but very quiet.

Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.—1s. 3d. per lb.
Crimson	1s. 6d.—1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Cheaper at 10½d.—1s. 1d. per lb. Ample supplies now available.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.—6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

In sympathy with most trades, this market is now a little easier.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8—£10 15s. per ton d/d, according to locality of market and type of charcoal. Demand easier.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2s. per gall. 24° Tw.
Red Liquor	1s 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P. Firm market as to price but demand quiet.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5–£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d. per lb. spot. 1s. 1½d. per lb. for forward delivery
Crude 60's	3s.—3s. 6d. per gall. Market firmer for early delivery.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 10d.—2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d.—11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8½d.—9d. per gall.
Benzole—	Market uncertain. Prices doubtful.
Crude 65's	1s. 1d.—1s. 1½d. per gall.
Standard Motor	1s. 4d.—1s. 6½d. per gall. Business slack, abundant supplies.
Pure	1s. 9d.—1s. 11d. per gall.
Toluole—90%	1s. 8d.—1s. 10d. per gall. Not many enquiries. Easier.
Pure	2s. per gall. Not much inquiry.
Xylol	2s. 3d.—3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	11d. per gall. Not much business.
Middle Oil	8½d.—10d. per gall. Market uncertain.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—9d. per gall.
Solvent 90/160	1s. 5d.—1s. 7d. per gall. Quiet.
Solvent 90/190	1s. 4d.—1s. 7d. per gall. Market quiet.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business passing.
Whizzed or hot pressed	£11—£13 per ton. More inquiries.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton
Pitch, medium soft	140s.–150s. per ton. Autumn delivery. No buyers at present.
Pyridine—90/140	18s.—20s. per gall. Demand good.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb.
Acid Sulphanilic	1s. 1½d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb.
Benzidine Base	5s. 2d. per lb. 100% basis d/d.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Quiet.
m-Cresol 98/100%	2s 1d.—2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
d-Dichlorbenzol	£70 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£65 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.

m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains exceptionally dull and orders continue to be very scarce owing to holidays and disturbed shipping conditions.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	2s. 11d.—3s. 1d. per lb. for cwt. lots. Market much weaker.
Acid, Benzoic	2s. 3d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 5½d.—1s. 8d. per lb., less 5%. Market weaker.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.—2s. 3d. per lb. Limited demand.
Acid, Tannic	3s. 1d. per lb. would now be accepted.
Acid, Tartaric	1s. 3d.—1s. 3½d. per lb., less 5%. Demand below normal but improving. Stocks accumulated during the cold spring now being used up and a rise in price not improbable.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very weak.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	19s. per lb. now quoted with little inquiry.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31—£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source.
Calcium Lactate	2s. 6d. per lb. for best makes. Better inquiry.
Chloral Hydrate	3s. 9d. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots. Very firm. Higher prices expected.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	The Referee has decided that it must in future be excluded from the list of dutiable articles under the Safeguarding of Industries Act.
Guiacol Carbonate	8s. 3d. per lb. Spot supplies short.
Hexamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—Light Commercial	£37 per ton net.
Magnesium Oxide—Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality and quantity.
Menthol	38s. per lb. spot, less 2½%. Slightly weaker.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 12s. per bottle.
Methyl Salicylate	2s. 3d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine	Alkaloid—Cryst. 10s. 11d., Precip. 10s. 8d., Acetate 8s. 6d., Hydrochlor. 8s. 6d. Sulphate 8s. 6d. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb.
Phenacetin	6s. per lb. Lower in value.
Phenazone	7s. per lb. In better demand, especially for small quantities.
Phenolphthalein	6s. 9d. per lb. Supplies still short.
Potass. Bitartrate—99/100% (Cream of Tartar)	94s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.—3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	10½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 8d. per lb. Very quiet. Lower in value.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s. 3d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 6d. per lb., and Crystal at 2s. 7d. per lb. Market still very quiet.
Sod. Sulphite, anhydrous	£27 10s.—£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.

Thymol	15s. per lb. for cwt. lots of natural recryst.

TRADE NOTES

French Company News

It is reported from France that the Cie des Produits Chimiques et Electrometallurgiques d'Alais et de la Camargue has made an agreement with English and American producers of aluminium for the joint control of the Société Norvégienne des Nitrures.

The Société Industrielle du Celluloid has the extension of the productive capacity of its factories under consideration and is reported to be discussing amalgamation with an important competitor, the Société Génerale pour la Fabrication des Matières Plastiques.

Chlorobenzene for the manufacture of sulphur black is now being produced by the Société d'Electrochimie, d'Electrométallurgie et des Aciéries Electriques d'Ugine. During 1922 this company sold 15,000 t. of cyanamide in France, as well as quantities of carbide, aluminium and ferro-alloys.

The output of dyes by the Cie Nationale des Matières Colorantes et des Produits Chimiques increased by 125 per cent. during 1922. The company has recently greatly increased its research department.

The Société Chimique Usines du Rhône, which, with the Comptoir des Textiles Artificiels, has established a company for the manufacture of *Rhodiaseta* cellulose acetate silk, has now begun to market this silk. The Société has purchased the sequestrated factory of the A.-G. für Anilin Fabrikation at Fons to provide room for development and has extended its power station at Roussillon by oved 400 kw.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications made in July for licences under the Dyestuffs (Import Regulation) Act, 1920, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 371, of which 264 were from merchants and dealers. To these should be added 24 applications outstanding on July 1, making a total for the month of 395. These were dealt with as follows:—

Granted, 246 (of which 227 were dealt with within 7 days of receipt).

Referred to British makers of similar products, 70 (of which 66 were dealt with within 7 days of receipt).

Referred to Reparation supplies available, 50 (all dealt with within 2 days of receipt).

Outstanding on July 31, 29.

Of the total of 395 applications received, 336, or 85 per cent., were dealt with within 4 days of receipt.

EDITORIAL

AN interesting, but by no means novel point has been raised by a letter from an anonymous correspondent which we print in another column. He writes: "To science the importance lies in the facts, the honour of priority being quite subsidiary." It would be hard to find anyone to dispute the importance of "facts," but we are certain that the more human side is not quite so subsidiary as our correspondent thinks. The reference in this case is to the question whether the element of atomic number 72 shall be called celtium or hafnium. Two names cannot be used, so the facts relating to the question have been published so that those who run may read. This is only just, and is, moreover, necessary. It is possible, however, that, a few centuries hence, it may not matter who first discovered this or that element. But unless human nature undergoes a sea change, there will assuredly be no lack of learned men who will toil to rediscover the names of the original discoverers if they have been forgotten. At one time history consisted largely of the study of the battles and doings of kings, and although the economic side is now no longer neglected, names such as those of Paston or Pepys merely replace those of dignitaries of the court. The personal element still remains. Archimedes, it is said, regarded his mechanical discoveries as beneath the dignity of "pure science," and attached most importance to his treatises; but every one, except a few specialists, at once thinks of his water-screw when his name is mentioned. What must our correspondent think of Prof. J. R. Partington and Mr. E. J. Holmyard (a letter from whom is also printed in this issue) and some others for trying to ascertain the identity of Geber and even thinking that his identification is one of the most important problems in the history of chemistry? It is no new thing for scientists to be told that they must be content—anonymously—with the beauty and delight of their discoveries for reward. Yet what interest is aroused when the authorship of a work of art is questioned! One can readily imagine the eagerness to know whether it was genuine or not. No one will, we think, deny artistic merit to great scientific discoveries, and it is not stretching the point to claim that the intuition necessary to the scientific investigator is not unrelated to the inspiration of the artist. And as there is no reason to claim that Clio or Urania were in any way inferior to their sister muses, so we cannot justly demand from science an abnegation which besides being unnecessary and unnatural, is not requested from other departments of human activity.

* * *

Of interest in this connexion is a recent announcement in *The Times* to the effect that the Intellectual Co-operation Commission of the League of Nations has decided to submit to the Council and Assembly of the League a draft convention "to establish for scientific discoveries a copyright similar to that granted for literary and artistic work." We must confess that the precise meaning of the proposal is not very clear, as under English copyright law, at least, the scientist is reasonably well protected. Many scientific ideas, however, are not suitable subject matter for a patent, but if the proposal, as it would seem, leads to the general enforcement of the principle that credit is to be given where credit is due, it will be welcomed. As our contemporary, *Nature*, remarks, "even if the proposal should be found to concern itself only with the literary expression of a discovery, it may yet serve a useful purpose, since it may result in directing public attention once more to the callous neglect of the interests of those to whom the world in the past has been so vastly indebted." Evidently there is a dislike of anonymity amongst scientific men, but even if their wishes are abundantly realised it is most devoutly to be hoped that there will be no extension of the increasing custom of labelling reactions or theoretical deductions with the names of their authors.

DENATURED ALCOHOL IN CANADA*

By ROSS E. GILMORE†

Denatured alcohol, according to the definition of the Canadian Inland Revenue, means "alcohol in suitable admixture with such denaturants as to render it . . . . non-potable and to prevent recovery of the ethyl alcohol." The object of denaturing is to permit, free from duty, the use of ethyl alcohol for purposes other than drinking, *i.e.*, for use in the arts and industries and for fuel, light and power. Denatured alcohol may also be termed industrial alcohol. It is, however, mainly that part of the total non-potable industrial alcohol which is tax free that is known as denatured alcohol. A full discussion of the manufacture, etc., of industrial alcohol is beyond the scope of this paper, and apart from reference to special regulations for using commercially pure, taxable ethyl alcohol in bond for certain industrial purposes the following will deal with "denatured alcohol" rather than "industrial alcohol" in general.

Completely and Specially Denatured Grades

The definition for "denatured alcohol" given above is to be found in Article 368, Part X, Chapter 52, Inland Revenue Act, Canada. According to the same article, "specially denatured" means "alcohol in suitable admixture with such special denaturants as have been approved by the Minister." According to Article 371, "denatured alcohol is sold without restriction while specially denatured alcohol is sold only to licensed dealers to be used in the arts and industries in cases where denatured alcohol would be unsuitable, and under such conditions as the Minister may by regulations prescribe"; in other words its sale is restricted. In the United States the terms "completely denatured," "specially denatured" and "formula" are used. The completely denatured formulæ are those which have been denatured in accordance with fixed formulæ, for sale to the general public with very little supervision, and the specially denatured formulæ are those, not so completely denatured and not for sale to the general public, that can be obtained only under a heavy bond. For the purpose of this paper the word "unrestricted" will apply either to the Canadian "denatured alcohols" or to the U.S. denatured alcohols and "restricted" will apply to the specially denatured grades or formulæ.

The use of commercially pure ethyl alcohol not denatured is authorised in Canada to be used in bond and under varying rates of excise duties as follows:—

I. For the manufacture of crude fulminate of mercury, pure ethyl alcohol is allowed free. The various regulations controlling use in bond must, however, be strictly adhered to.

II. Hospitals and universities may obtain pure ethyl alcohol on payment of the regular excise duty ($9.00 per proof gallon) with the provision that 99 per cent. of the duty is refundable. Besides the undenatured industrial alcohol obtainable practically tax-free in this way there are two restricted grades of denatured alcohol; No. 1 special and No. 1 F for use in hospitals and universities.

III. Manufacturers of various chemical products may obtain ethyl alcohol or domestic spirits as it is called by the payment of an excise duty ranging from 15 cts. to $2.43 per proof gall. Under the 15 ct. rate come:—Collodion, ethyl bromide, ethyl chloride, chloroform, sulphuric ether, soap, etc., as well as sensitised photographic emulsions in the manufacture of which phenol and methyl alcohol are required to be added to the ethyl alcohol before use. Vinegar comes under the 27 ct. per proof gall. excise and perfume spirits under the 75 ct. rate. Proprietary medicines, pharmaceutical preparations, extracts and essences are the uses listed under the $2.40 to $2.43 rates of excise.

Table I gives a list of the ten grades of denatured alcohol authorised in Canada. It will be noticed that the three unrestricted sale grades, viz., No. 2 Standard, No. 2 Benzol and No. 2 Pyridine, represent roughly 42 per cent. of the total consumption. Grade No. 1 Benzine representing 37 per cent. of the total consumption is a restricted sale grade. No. 1 Standard for the same use as No. 1 Benzine represents an average of about 6 per cent. of the consumption, leaving only 15 per cent. of the total consumption for the remaining five grades of specially denatured alcohol for specially authorised uses.

Denaturants and their Comparative Importance

In the manufacture of denatured alcohol the denaturant must comply with the Government specifications and regulations and then in order to be in demand commercially, it must have the properties peculiar to the use to which it is to be applied.

The Government specifications require that the denaturant when mixed with grain alcohol should (a) render the mixture non-potable and (b) should make the recovery of the separate ingredients, especially the ethyl alcohol, as difficult as possible. Persons "who attempt to reclaim the ethyl alcohol or other ingredients of a denatured alcohol are liable to a heavy penalty." From the health standpoint it would seem a good denaturant is one which when taken internally either purposely or by accident would cause sickness but not death. The relation of toxicity of the denaturant to the non-potability will be referred to later. For industrial use denatured alcohol must be miscible with 95 per cent. grain alcohol, and must have the same general solvent properties as the ethyl alcohol product to which it is added. A special requirement of good denaturants is that they be miscible in practically all proportions with water.

---

* Paper read at the March meeting of the Ottawa Section of the Society of Chemical Industry.

† Formerly Chief Chemist, Standard Chemical Co., Montreal.

The original and most usual denaturant is wood alcohol, of which methyl alcohol is the main ingredient. The term "wood alcohol" is, however, not allowed in commerce. In Canada the official nomenclature is "methyl hydrate" and in the United States "methanol." As a denaturant the term wood alcohol is more to the point rather than the term methyl alcohol, as "wood alcohol" in industry is an impure product and "pure methyl alcohol" is a highly refined grade. According to the specifications, "methylating spirits," as the denaturant grade of methyl hydrate is called, must contain certain impurities which give the grain alcohol to which it is added a disagreeable odour and other repugnant characters. These impurities are certain ketone and higher alcohols which are necessarily left in the methyl hydrate in order that it may conform to the acetone-content specification on one hand, and the bromine absorption specification on the other hand. Methyl hydrate used for methylating purposes is known by the trade as "Government grade," and is different from other grades of methyl hydrate, the Government grade being the poorest. Columbian spirits and pure methyl alcohol are the best, and their use is permitted in specially denatured alcohol in the United States, but not in the ordinary completely denatured alcohol grades.

Owing to its importance as a denaturant for grain alcohol the question of wood alcohol deserves special attention. Its merits appear to more than balance its more or less objectionable characteristics, and it should be pointed out that most of its disagreeable properties are there because the relevant laws and specifications require them to be present to make it an effective denaturant. The Canadian Government specifications for methyl hydrate (wood alcohol) used for denaturing purposes may be summarised as follows:—*Specific Gravity* at 60° F—not less than 0·815, *i.e.*, not weaker than 95·2 per cent. vol. (Thorpe's tables), which is equivalent to approximately 67 over proof. *Colour*—colourless to pale straw colour. *Volatility*—must be completely volatile on a steam bath at 100° C. *Miscibility*—must give a clear or only faintly opalescent solution on diluting with twice its volume of water. *Acetone content*—not less than 5 g. and not more than 15 g. per 100 c.c. *Bromine Absorption.*—It must contain a sufficient quantity of (pyroligneous and allied) impurities so that not more than 25 c.c. or less than 15 c.c. shall be required to decolorise a standard solution containing 0·5 g. of bromine. *Other requirements.*—It shall be of such a character as to render ethyl alcohol when diluted with water unfit for use as a beverage when methyl hydrate is present in the proportion of one part of ten parts of ethyl alcohol.

The bromine absorption specification may be considered the most important in that it is meant to ensure that the alcohol contains sufficient impurities to render the ethyl alcohol with which it is mixed non-potable. The bromine number is an indication of the purity or refinement of the methyl hydrate used. The higher the bromine number the purer the grade and vice versa; a pure grade ranges over 1000 in bromine number, whereas the most impure grades have bromine numbers as low as 3 to 5. Therefore a methyl hydrate with a bromine number ranging between 15 to 25 cannot be considered other than a poor, impure grade. The impurities present to give this low bromine number range are mostly unsaturated ketones other than acetone, unsaturated alcohols with boiling point ranges above that of methyl alcohol, as well as varying amounts, usually small, of aldehydes and amines. The bromine absorption specification is effective in that it gives the alcohol mixture an objectionable odour and thus helps to render the resultant denatured alcohol non-potable. The impurities necessary, according to the bromine number specifications, also make the resultant methylated spirits less valuable as a solvent for certain specific purposes, and, of course, the larger the percentage of wood alcohol present the more objectionable it is in this respect and vice versa. But to do away with, or even to raise the bromine number specifications more than slightly would be defeating the original and still valid purposes of using wood alcohol as a denaturant.

DENATURANTS OTHER THAN METHYL HYDRATE

In denatured alcohol grades where the percentage of wood alcohol is allowed to be low, other denaturants such as pyridine bases and benzine (kerosene) are present. In Canada these two are the only ingredients used with methyl hydrate. Benzine used as a denaturant in Grade No. 1 Benzine is derived from petroleum. It must be of such a character as to impart a decided odour to ethyl alcohol when mixed in proportion of 0·5 per cent. by volume. The merits of benzine as a denaturant seem to lie solely in its property of giving grain alcohol with which it is mixed an offensive odour and taste. Although the alcohol denatured with benzine finds extensive use as a solvent, the presence of benzine makes the grade unsatisfactory as a solvent in the manufacture of certain soaps, drugs and chemicals. When present in a denatured alcohol in conjunction with wood alcohol it helps to make the ethyl alcohol difficult to refine, which, of course, is one of the main purposes of a denaturant.

Pyridine bases as used as a denaturant in grade No. 2 Pyridine must conform to specifications of colour, reaction with cadmium chloride, behaviour with Nessler's reagent, boiling point, miscibility with water, content of water, and alkalinity. The presence of the pyridine bases is quite effective in giving the ethyl alcohol to which it is added a disagreeable odour. Denatured alcohol containing pyridine bases should find more general use as a solvent but for certain purposes it is quite unsuitable. The alkaline nature of the pyridine bases, which can be neutralised by acids to form salts, and their high boiling points—50 per cent. distillable at 140° C. and 90 per cent. at 160° C.—are not in respect to rendering recovery of ethyl alcohol favourable. When used in conjunction with wood alcohol, however, this defect is somewhat remedied.

Among the denaturants used not in conjunction with wood alcohol are benzol, pine oil and nitrobenzol. These three ingredients are used together in what is known as grade No. 2 Benzol. The benzol is subject to certain specifications in respect to insolubility in water and boiling point range, whereas the pine oil and nitrobenzol used in conjunction with benzol as denaturants must meet specifications mainly in respect to specific gravity. The purpose of these last two substances is to mask the odour of and to impart a burning taste to the alcohol. In this respect a combination of these three ingredients makes an effective denaturant mixture. Alcohol denatured with benzol is used principally for burning and anti-freeze purposes, and although it is used to a certain extent as a solvent, its use for that purpose seems to be limited.

The denaturants hitherto discussed are used in the "denatured alcohols" for unrestricted sale. For the specially denatured grades special denaturants are allowed. Those authorised in Canada are :—Iodine, potassium iodide, ether, cadmium chloride, ammonium iodide, nicotine compounds, brucine sulphate and diethylphthalate. Practically all these special denaturants are effective in making the alcohol poisonous, but they are not nearly as effective in imparting an offensive odour as are the several denaturants previously discussed. Practically all these special denaturants are open to the criticism that they are more or less easy to recover, a defect which is somewhat remedied by the regulations ensuring that their sale and use are under permit and heavy bond.

Recoverability and Toxicity

It is quite possible to recover the different denaturants by special laboratory rectification methods ; some are easy to recover and some are quite difficult. Ease of recovery of the denaturants does not necessarily mean ease of recovery of the ethyl alcohol, but indications are that the more easily the denaturants are removed, the easier it is to recover the ethyl alcohol in a more or less pure state ; and as a general rule rectification on the commercial scale is more efficient than in the laboratory. It is more difficult to separate by rectification, into their component parts, two liquids which are similar in composition and which are both miscible in all proportions in water than two liquids of dissimilar molecular formulæ and of different chemical properties. For this reason it is difficult to separate wood alcohol from grain alcohol. The immiscibility in water of the denaturants tends to make their recovery easier, and the large difference between the boiling point of the denaturants and that of the ethyl alcohol is also an important factor in the ease of recovery of the components. Oils not miscible with water, such as benzol and benzine, and oils or solids with high boiling points such as pyridine bases, iodides and brucine sulphate, are therefore not of high efficiency in making the recovery of ethyl alcohol difficult by ordinary dilution and rectification methods.

The question of toxicity of denaturants is important. All denaturants used in the manufacture of denatured alcohol have toxic properties which make grain alcohol poisonous to drink, the degree of toxicity of the denatured alcohol depending not only on the poisonous properties and quantity of the denaturant ingredient, but also on the amount of denatured alcohol taken internally. Most of the denaturants used give warning by causing characteristic sickness of a more or less violent nature from which recovery is possible, providing too much has not been imbibed. Some maintain that this is the main purpose of a denaturant, in respect to rendering the ethyl alcohol non-potable, but this viewpoint seems to be midway between two extremes, viz., (a) that the denatured alcohol should have such an offensive odour and disagreeable taste that it cannot get past the nose or tongue, and (b) that the main purpose of denaturing alcohol is to make the alcohol extremely dangerous when taken internally. Very few exact data are available, especially on the toxic effect of the different denaturants and of their individual ingredients. If the middle viewpoint is favoured, viz., that a denatured alcohol should not kill but should cause pain and sickness, this would be an argument for reducing the quantity of denaturant to the minimum for this effect when ordinary quantities are taken. All this has a bearing on the analytical work required of the chemist, and until some upper or lower limits of the ratio of toxicity of the denaturant to the quantity present in the final denatured alcohol are agreed on, a great deal of misunderstanding is likely to prevail. For example, why is it necessary, other than for scientific purposes, to use both qualitative and quantitative methods for the determination of methyl alcohol in quantities below, say, 1 per cent. (let alone 0·1 per cent.) unless it is known

TABLE I

DENATURED ALCOHOLS AUTHORIZED IN CANADA

Grade	Composition	General (approved) uses	Conditions of sale	% of total consumption (1922) %
No. 2 standard	70 parts ethyl alcohol 30 ,, methyl hydrate (not more than 50% ,,)	Burning and antifreeze ; paint and varnish industry	Unrestricted	7
No. 2 benzol	100 parts ethyl alcohol 2·5 ,, benzol 0·5 ,, nitrobenzol 0·2 parts pine oil	Burning and antifreeze ; paint and varnish industry	Unrestricted	5
No. 2 pyridine	100 parts ethyl alcohol 2 ,, methyl hydrate 1 ,, pyridine bases	Burning and antifreeze ; paint and varnish industry	Unrestricted	30
No. 1 benzine	90 parts ethyl alcohol 9 ,, methyl hydrate 1 ,, benzine (kerosene)	Manufacture of paint, varnish and shellac	Restricted	37
No. 1 standard	80 parts ethyl alcohol 20 ,, methyl hydrate (not more than 25% ,, ,,)	Same as for No. 1 benzine	Restricted	6
No. 1 special	90 parts ethyl alcohol 10 ,, methyl hydrate	Hospitals only	Restricted	1
No. 1 D (iodine)	100 parts ethyl alcohol 2·5 ,, iodine 1·5 ,, potassium iodide	Tincture of iodine B.P.	Restricted	9
No. 1 A	100 gall. ethyl alcohol 65 lbs. sulphuric ether 3 ,, cadmium iodide 3 ,, ammonium iodide	Collodion ; photographic prints, engravings, enlargements, etc.	Restricted	¼
No. 1 C	100 gall. ethyl alcohol 5 ,, 40% nicotine soln. (plus yellow and blue dyes)	Deodorant solutions for cigars, cigarettes, smoking and chewing tobacco	Restricted	¾
No. 1 F	1 gal. ethyl alcohol 2·5% diethylphthalate 5 grains brucine sulphate	Rubbing alcohol compound	Restricted	4

definitely just how much ethyl alcohol with this percentage can be taken internally without permanent injury ? By qualitative methods dilutions lower than one part of methyl alcohol in 10,000 parts of solution can be detected and the lower limit of 0·1 per cent. appears quite determinable by quantitative methods. It is well known that the impure grades of wood alcohol are poisonous when taken internally, but very little seems to be known of the comparative toxicity of the different ingredients that make up the complex organic mixture known as methyl hydrate (wood alcohol). If it is true that pure methyl alcohol is far less toxic than the higher alcohols, ketone, aldehyde and other impurities, why should the analytical chemist have to prove or disprove the presence of small quantities or traces of methyl alcohol ? The poisonous qualities of a denatured alcohol, in which, say, the presence of methylated spirits is suspected, may be due to impurities normal to grain alcohol, *e.g.*, fusel oils, etc., to a greater extent than to traces of methyl alcohol or other denaturants.

DENATURED ALCOHOLS AUTHORISED IN GREAT BRITAIN

According to the information at hand apparently only three different grades of denatured alcohol are admitted to the tax free list in Great Britain. These are set out in Table II. All three grades contain wood

TABLE II

DENATURED ALCOHOLS AUTHORISED IN GREAT BRITAIN

Name	Composition	General uses	Conditions of Sale
(Grade 1) Industrial methylated spirits	95 parts ethyl alcohol 5 ,, wood naptha	Special manufactures such as artificial leather, varnishes and polishes, soaps, drugs, and fine chemicals, gas mantles, etc.	Restricted
(Grade 2) Mineralised methylated spirits	89⅝ parts ethyl alcohol 10 ,, wood naptha ⅜ ,, petroleum	General industrial purposes, chemical and oil products	Restricted
(Grade 3) Power methylated spirits	92 parts ethyl alcohol 5·0 ,, benzol 2·5 ,, wood naptha 0·5 ,, crude pyridine (plus yellow and red dye)	Motor fuel preparations	Restricted

alcohol, and all come under the class of restricted denatured alcohols, and in this respect they are all to be considered specially denatured alcohols as compared with those of Canada and the United States. The third grade, viz., power methylated spirits is a new grade, authorised since August 18, 1921 (Statutory Rules and Orders, 1921, No. 1318). No considerable quantity of this grade appears to have been consumed and the percentage of total consumption for grade 1 and 2 is given as roughly 70 per cent. and 30 per cent. respectively. British grades 1 and 2 are quite similar to the United States specially denatured formula No. 1 and the Canadian grade No. 1 Benzine.

DENATURED ALCOHOLS IN THE UNITED STATES

As mentioned above the denatured alcohols authorised in the United States are divided into two main classes, viz., completely denatured and specially denatured. There are six different grades of completely denatured alcohol for sale to the general public with very little restriction or supervision. The six U.S.A. completely denatured formulæ are as follows:—

Formula No. 1	100	gall.	ethyl alcohol
	10	,,	approved wood alcohol
	½	,,	approved benzine (kerosene)
Formula No. 2	100	parts	ethyl alcohol
	2	,,	approved wood alcohol
	½	,,	approved pyridine bases
Formula No. 3	100	parts	ethyl alcohol
	5	,,	sulphuric ether
	2	,,	benzene
	1	,,	pyridine
Formula No. 4	100	parts	ethyl alcohol
	2·5	,,	approved benzol
	0·5	,,	nitrobenzol
	0·2	,,	pine oil
Formula No. 5	100	parts	ethyl alcohol
	2	,,	approved wood alcohol
	¼	,,	pyridine bases
	½	,,	benzine (kerosene)
Formula No. 6	100	parts	ethyl alcohol
	2	,,	approved benzol
	½	,,	approved pyridine bases
	½	,,	approved benzine (kerosene)

The following comparison is to be noted:— U.S.A. formulæ No. 1, 2 and 4 are similar to Canadian Grades No. 1 Benzine, No. 2 Pyridine, and No. 2 Benzol respectively.

SPECIALLY DENATURED ALCOHOLS IN THE UNITED STATES

Up to the end of 1922, seventy-five different formulæ of specially denatured alcohols obtainable only under heavy bond for use in manufacturing processes were authorised in the United States. These formulæ range in number from 1 to 47 inclusive, and as high as five different formulæ, all for the same general use, follow the original numbers, *e.g.*, 38, 38A, 38B, 38C, 38D and 38E. Before a manufacturer can obtain supplies, a permit must be obtained and a heavy bond executed in duplicate. The details of these different formulæ can be found in Appendix to Regulations 61, dated Sept., 1922 (Treasury Department, United States Internal Revenue).

The composition of formula No. 1, specially denatured alcohol, is as follows:—100 galls. of pure ethyl alcohol and 5 galls. of approved wood alcohol. This formulæ is authorised for over 225 uses, and is apparently intended to allow the use of tax-free alcohol for articles of commerce in the manufacture of which none of the six completely denatured alcohols is found to be suitable. In Canada there is as yet no grade authorised similar to this U.S.A. specially denatured formulæ No. 1. In Great Britain, however, Grade No. 1—industrial methylated spirits—is practically the same as formula No. 1.

Formula No. 4, of which the denaturing ingredients are nicotine solution, yellow dye and brilliant blue dyes, is somewhat similar to the Canadian grade No. C. It is used for tobacco deodorant solutions. Formula No. 5, containing sulphuric ether, cadmium iodide and ammonium iodide as denaturants, is similar to the Canadian grade No. 1A, and is used for photographic purposes. Formula No. 25, containing iodine and potassium iodide, is similar to the Canadian grade No. 1 Iodine and is used for tincture of iodine. Formula No. 46 containing phenol and methyl salicylate (oil of wintergreen) is the antiseptic and bathing alcohol preparation corresponding to the Canadian grade No. 1F, containing brucine sulphate and diethylphthalate.

A partial list of the denaturants of the other formulæ for the U.S.A. specially denatured alcohols is given below:—

Formula	Denaturants	Uses (list not complete)
2	Camphor and commercially pure methyl alcohol	Celluloid products
3	Castor oil, caustic soda, lye and pure methyl alcohol	Transparent soap and shampoo preparations
13A	Sulphuric ether	Anæsthetic ether, dry food products, extracts, neosalvarsan, etc.
18	Vinegar (9% acetic acid)	Vinegar, acetone, etc.
23 and 23A	Acetone and benzol or acetone alone	Liniments and lotions for external use only
28 and 28A	Benzol or gasoline	Motor fuel
31	Soap and glycerin	Tooth paste
34	Tetrachlorethane	Artificial silk
38 and 38D	Methyl salicylate and zinc chloride or menthol and formaldehyde	Mouth washes and dentifrices
40	Brucine sulphate and acetone	Perfumes and toilet preparations
44	Normal butyl alcohol	Varnishes, varnish removers, etc.
45	Refined shellac	Candy glaze

The denaturants used in these U.S.A. specially denatured alcohols are open to somewhat the same criticism as the denaturants used for the Canadian restricted specially denatured grades in that (a) very few of them impart to the ethyl alcohol with which they are mixed an offensive odour and (b) for very few can the claim be made that it is quite difficult to recover either or both the denaturant and original ethyl alcohol. Practically all, however, render the ethyl alcohol with which they are mixed poisonous when taken internally in quantities other than small doses. Objections both to the lack of offensive odour, to the non-potability and to the comparative ease of recovery of the ingredients of the specially denatured alcohols are, however, met by the permit and bond laws and regulations governing their use.

The denatured alcohols authorised in Great Britain, Canada and United States can be compared as follows :—

	Great Britain		Canada		U.S.A.
Total number of (tax free) grades authorised ..	3	..	10	..	81 (*a*)
(*b*) Number of completely denatured (tax free) grades (sale unrestricted) ..	0	..	4	..	6
Number of specially denatured (tax free) grades (sale restricted by permit and bond) ..	3	..	7	..	75
Number of grades using wood alcohol :					
As sole denaturant..	1	..	3	..	1
As part denaturant..	2	..	2	..	13 (*c*)
Number of grades not using wood alcohol ..	0	..	5	..	67

NOTES

(*a*) One of these, viz., formula No. 7, is reported as revoked and formula No. 1 substituted.

(*b*) Only the unrestricted grades are, for the purpose of this table, considered as completely denatured.

(*c*) The wood alcohol used in 13 part denaturant and 1 sole denaturant formulæ is comprised of both the regular approved quality and the commercial pure methyl alcohol. Out of the total of fourteen, 8 contain wood alcohol as in (approved) specifications and 6 pure methyl alcohol as part denaturant.

INDUSTRIAL ALCOHOL FOR MOTOR FUEL

A grain alcohol product to be used as motor fuel is logically a denatured alcohol. As yet no special grade is authorised in Canada for use as motor fuel, but there is apparently little reason other than price why for example unrestricted Grade No. 2 Pyridine should not be considered for that purpose. In the United States at present, two formulæ, viz., 28 and 28A containing 10 per cent. benzol and 1 per cent. gasoline, respectively, as denaturants, have been authorised as specially denatured grades for use in the manufacture of motor fuels. They are not used alone but are apparently blended before being offered for sale.

The grain alcohol in these denatured alcohols used for motor fuel is 190 proof U.S.A. and not less than 166 proof British (*i.e.*, 95·0 and 94·4 per cent. vol., respectively). A great deal of research work is being done on the use of 95 per cent. ethyl alcohol, benzol, etc., in internal-combustion engines. This work seems to show that the use of ethyl alcohol and benzol, either separately or mixed, allows the development of high compression engines, whereas development appears restricted when using petroleum products and especially when it is desired to utilise more of the kerosene fractions along with the gasoline. Results reported by Ricardo (*The Automobile Engineer*, August, 1921) show that the efficiencies for gasoline, benzol and ethyl alcohol do not vary much when used in an engine of comparatively low compression such as the automobile engines of to-day. On attaining the "highest useful compression," however, the increase of efficiency with 95 per cent. ethyl alcohol is as high as 25 per cent., compared with 17 per cent. with benzol and less than 9 per cent. with gasoline. These results would indicate that while at present ethyl alcohol and benzol are not more valuable per gall. for power purposes than gasoline, they may in the future.

DATES OF AUTHORISATION OF THE DIFFERENT CANADIAN GRADES

Up to 1882 the denaturing of grain alcohol was in the hands of individual licensees. From that date up to 1920 the denaturation and sale of denatured alcohol was carried out at Ottawa by the Inland Revenue Department. During the early part of this period four grades, viz., No. 1 and 2 Standard, No. 1 Benzine and No. 1 Special were authorised, one unrestricted and three for restricted sale under bond. Up to this time all grades were known as methylated spirits. On August 23, 1920, authorisation was given for the manufacture of denatured alcohol by licensed distillers in lieu of the Department.

COMPARATIVE SELLING PRICE AND COST FIGURES

In the following table the comparative prices of two grades of denatured alcohol in Canada, United States and England are given :—

	Quotations per imperial gall., December, 1922					
	Canadian		United States			English
			U.S. gall.	Imperial gall.		(Exchange $4.75)
Completely denatured alcohol—						
10% wood alcohol 0·5 to 1% benzine }	$1.00	..	($0.40)	$0.48	..	2s. 7d. ($0.62)
Specially denatured alcohol—						
Containing as denaturant 5% wood alcohol..	No grade	..	($0.43)	$0.52)	..	3s. 6d. ($0.83)

The quotation for Canada it is to be noticed, is about double that in the United States, while the selling price in England is about six-tenths of that in Canada. Canadian quotations for industrial alcohol used for the manufacture of vinegar are about 80 per cent. of that for the lower priced denatured alcohols. The price per gall. of the wood alcohol used as a denaturant is as a rule higher than the grain alcohol with which it is mixed, and the fact that the specially denatured grade containing less wood alcohol is quoted (both in England and the United States) at a higher price, raises the question as to whether the quality of the ethyl alcohol product used is better.

The chief facters that make the cost of denatured alcohol so much higher in Canada than in the United States may be summed up as follows :—(1) Higher raw material cost; higher freight and duty rates. (2) Higher handling, sales, and distribution costs. (3) Higher overhead costs—mainly higher capitalisation per unit output. The last named factor, viz., higher overhead charges coupled with the necessity of distribution over a large, sparsely populated area, is worthy of note.

QUALITY AND PRICE

In refining industrial grain alcohol from the mash "heads" and "tails" are produced, as well as high grade ethyl alcohol. The "heads" contain the lower boiling-point organic impurities associated with ethyl alcohol produced by fermentation, whilst the "tails" contain the higher boiling alcohols such as fusel oil. A certain amount of the poor grade heads and tails is not marketable, but there is no apparent reason why those higher grades possessing good solvent, antifreeze and other properties should not be used in manufacturing denatured alcohol. The purest grade of ethyl alcohol is apparently used for making products as absolute alcohol and Cologne spirits; and the alcohol to be denatured is known as "commercial grade." This latter grade will contain the heads and tails and the amount used and purity of these will in turn determine the quality of the ethyl alcohol product going to make up the different grades of denatured alcohol.

Although the comparative demand for, first non-potable industrial alcohol (both undenatured and denatured) and second, the different grades of denatured alcohol, will doubtless control the amount of more or less chemically impure heads and tails used, it would seem that if more than one quality of commercial ethyl alcohol were possible, the less pure alcohol should be assigned to the general burning and antifreeze unrestricted grades and the best quality to the specially denatured alcohols to be used for special solvent and other manufacturing purposes.

Specially denatured alcohol U.S.A. Formula No. 1 calls for "pure ethyl alcohol." In England the quality of the ethyl alcohol used in their grades No. 1 Methylated spirits is regulated apparently only by the special demands of the buyers in respect of quality. Therefore the general usefulness of this grain of denatured alcohol depends on the quality of the grain alcohol used, as well as on the quantity and quality of the denaturant. This should be borne in mind when studying and comparing the industrial merits of any denatured alcohol. In Canada commercially pure ethyl alcohol is obtainable at excise duties ranging from 15 cts. to $2.43 per proof gall., *i.e.*, from 25 cts. to $4.00 per gall. of 95 per cent. (vol.) alcohol. These rates, however, apply only for purposes specifically authorised and the undenatured alcohol is obtainable only by special permit and under bond according to rules and regulations of the Inland Revenue Department.

ETHYL ALCOHOL DISTILLATION INDUSTRY IN CANADA

Total alcohol produced in Canada	Proof gall.	Selling value $
1918 (Whiskies and other spirits)	3,702,000	2,782,000
1919 (Potable and non-potable alcohol)	2,057,000	1,250,000
1920 (,, ,, ,, ,,)	3,308,000	2,802,000
1921 (,, ,, ,, ,,)	4,026,000	—

Total industrial (non-potable) alcohol produced in Canada	Proof gall.	Percentage of total potable and non-potable alcohol produced
1919	1,777,000	86
1920	2,223,000	67
1921	1,347,000	33

Estimate for the year 1922	Estimated percentage of total industrial non-potable alcohol produced	Estimated percentage of total potable and non-potable alcohol produced (1921 figures)
Industrial alcohol (taxable)	60	20
Denatured alcohol (tax free)	40	13
	100	33

Note—The proof gallon and selling value figures in the above table are from the Dominion Bureau of Statistics reports on the Liquor Distillation Industry in Canada for the years 1918 to 1921.

The above table indicates what percentage of the total ethyl alcohol produced in Canada is marketed as denatured alcohol. Of the total (non-potable) industrial alcohol produced, it is estimated that 60 per cent. is used in the commercially pure state and is taxable, whereas 40 per cent. is denatured and tax free. These estimates are for the year 1922 and applying them to the 1921 production figures, it appears that the total denatured alcohol sold in Canada represents approximately only 13 per cent. of the total ethyl alcohol produced.

CRYSTALLINE LIQUIDS

PROF. SIR WM. J. POPE, K.B.E., F.R.S.

Experimental Lecture before the Science Masters' Association at Cambridge, January 3, 1923

Everyone is acquainted with what is understood by a solid crystalline material. A crystal is defined as an arrangement of matter in which every point is repeated with a similar environment throughout the structure; this definition furnishes the basis for investigating the number of different types of arrangement of points in space which may be expected to occur amongst crystalline structures.

The investigation of the geometrical possibilities has shown that 230 such types of arrangement exist; these are termed the homogeneous point systems, and may be classified according to their symmetry in the thirty-two known crystal classes, which in turn are distributed among the seven great crystal systems.

The correspondence between the results of the theoretical investigation of the possibilities and of the experimental study of solid crystalline material is so complete that this purely formal side of crystallography is now a completely worked-out branch of science. We are as yet, however, merely on the threshold of that subject for investigation which consists in determining the relation between crystalline structure and chemical constitution, and in this is, of course, included the study of the relation between the physical properties of such structures. More has been accomplished in this connexion during the last twenty years than throughout the whole previous history of science: at the same time, we have even yet but roughly sketched out the outline of the whole great subject which awaits investigation.

In commencing this lecture I should show you one or two of the phenomena met with in the investigation of solid crystalline substances. On allowing a melted chemical substance to cool it generally crystallises and, provided it crystallises in another than the cubic system, the crystals are doubly-refracting and can hence be distinguished by the interference colours which they present between crossed Nicol prisms. (Bromohydroxyhydrindene). It is often observed that one substance affects two crystalline forms each of which is stable throughout a certain range of temperature; cases of this kind are described as instances of dimorphism. Thus, mercuric iodide presents itself at ordinary temperatures as a scarlet substance crystallising in the tetragonal system, which changes suddenly into a bright yellow orthorhombic modification on heating; the conversion from the red to the yellow form occurs abruptly at 126°, the so-called transition temperature, whilst on cooling the reverse change takes place, although not with the same sharpness. [Shown with mercuric iodide.] Many substances undergo several such changes in crystalline form as the temperature is raised; a good example of this so-called "polymorphism" is provided by ammonium nitrate, which exists in five distinct forms, each stable throughout a definite range of temperature. The transition temperatures are 16°, 32°, 84° and 125°, and the form stable at the highest temperature is a cubic modification which melts at 170°. [Shown with ammonium nitrate]. The several polymorphous forms of any particular substance in general differ markedly in ordinary physical properties, such as solubility; thus, when a hot concentrated solution of sodium naphthionate is allowed to cool, the salt crystallises in broad feebly doubly-refracting sheets, which give place at ordinary temperatures to a strongly doubly-refracting form, crystallising in stout rhombs. The latter modification is much less soluble in water than the former, and it will be seen that each small rhomb becomes the centre of a pool of liquid bounded by the more soluble form; the pool and the central rhomb each become rapidly larger as the salt is dissolved away from the sides and is deposited on the rhomb of the more sparingly soluble substance. [Shown with sodium naphthionate].

These few examples have shown some of the characteristic differences between a crystalline solid and a liquid substance. The former possesses a geometrically homogeneous structure as revealed by the regular outline and the double refraction; the latter is amorphous and entirely lacking in regularity of structure, in accordance with the single refraction of the liquid. A large number of substances are known, however, which on melting yield a liquid showing one of the characteristic properties of solid crystalline substances, that, namely, of double refraction. Thus, crystalline *p*-azoxyanisol melts at 116° to an opalescent liquid which is strongly doubly-refracting, the double refraction being about twice as strong as that of calcite; this, as the temperature rises, shows a second transition point at 134°, the liquid becoming transparent and singly-refracting. The process is reversed on cooling and the opalescent doubly-refracting liquid stable between 116° and 134° is less viscid than either water or the clear singly-refracting liquid into which it is converted at 134°. [Shown with *p*-azoxyanisol]. The interference colours of the doubly-refracting liquid *p*-azoxyanisol between crossed Nicol prisms show that, as melted upon a glass microscope slide under a cover slip, no fixed orientation of the principal topical directions is established; on melting the substance in a cleavage cleft produced in a sheet of mica it is seen, however, that the crystalline structure of the latter gives direction to the optical properties of the doubly-refracting liquid. This is analogous to the regular manner in which crystals deposited from solution often arrange themselves upon a plate of crystalline material. [Shown with *p*-azoxyanisol in a mica cleft]. Other substances chemically related to *p*-azoxyanisol show very similar behaviour; thus, the homologue, *p*-azoxyphenetol, melts at 134° to a doubly-refracting liquid, which becomes transparent and singly-refracting at 168°. [Shown with *p*-azoxyphenetol].

Certain of these doubly-refracting liquids retain some element of the homogeneity of crystal structure possessed by the crystalline solid from which they are produced. Thus, crystalline ethyl *p*-azoxybenzoate melts to an agglomerate of double-refracting liquid sheets, and this, when cooled, gives a mass of doubly-refracting crystals each individual in which has approximately the original orientation; the trace of the solid crystal structure is thus conserved during melting and reappears on cooling. It is seen, in fact, that the liquid patches exhibit roughly the outline, between crossed Nicol prisms, of the original solid crystals. [Shown with ethyl *p*-azoxybenzoate.]

When a doubly-refracting liquid is kept suspended in a singly-refracting liquid in which it is partly soluble, it may be made to dissolve or to separate from solution by a change of temperature; in certain cases the doubly-refracting liquid can be caused to separate in globules which, from their interference bands, appear to be rotating rapidly. [Shown with mixtures of *p*-azoxyanisol, *p*-azoxyphenetol, resin and a trace of oleic acid].

Cholesterol and its esters give on melting doubly-refracting liquid phases which exhibit distinct granularity suggesting a certain regularity of structure. [Shown with cholesteryl chloride, acetate and benzoate]. With some of these the change of interference colour with change of temperature indicates a rapid variation of the degree of intensity of the double refraction with change of temperature. [Shown with cholesteryl cinnamate].

It has been seen that a marked analogy exists between the behaviour of solid crystalline substances and of these doubly-refracting liquids; it is interesting to discuss the reason for the similarity in behaviour. Three views have been put forward, and each strongly supported, in explanation of the existence of doubly-refracting liquids. The first suggests that the doubly-refracting liquid phase, which has temperature limits of stability between those of the singly-refracting liquid and the crystalline solid, represents a state of matter in which the kinetic forces, which are so completely subjugated in the solid crystalline state as to lead to the establishment of equilibrium of the particles of the material in one of the 230 point systems, have by the lowering of the temperature become partly subjugated in the doubly-refracting liquid and so give rise to patches of doubly-refracting liquid which have a transient homogeneous arrangement closely imitating the solid crystalline structure. The second view is to the effect that a sort of arrangement of molecules is set up in the doubly-refracting liquid which is not homogeneous in the sense of the definition, but consists in the establishment of a roughly parallel shaking together of long molecular complexes of definite shape. The first view is that the doubly refracting liquid has a homogeneous structure corresponding to a homogeneous point-system as is the case with solid crystals; the second is the basis of the so-called "swarm" theory of Bose, according to which the molecules lie merely banded together in roughly congruent positions. The third view, that of Tamman, is to the effect that the doubly-refracting liquids are two-phase systems somewhat of the nature of emulsions; it has been urged against this view that the supposed emulsions cannot be resolved by electrostatic forces or by centrifuging and that the limits of stability are defined by well-marked transition temperatures.

The recent physical work of Langmuir, Hardy, Adam and others has confirmed the conclusion long since drawn by organic chemists, that the chemical molecule is not spherical, but has different dimensions in different directions. Practically all substances which yield doubly-refracting liquids are of very complex composition and possess molecular constitutions in which the component atoms and radicles are arranged in a long chain, Thus, *p*-methoxycinnamaldazine,

$$p\text{-CH}_3\text{O·C}_6\text{H}_4\text{·CH : CH·CH : N·N : CH·CH·CH· : C}_6\text{H}_4\text{·OCH}_3,$$

and all the derivatives of cholesterol, $C_{27}H_{44}$, which latter almost certainly contains one normal chain of seventeen carbon atoms, form doubly-refracting liquids. [Shown with *p*-methoxycinnamaldazine.] If the molecules are ellipsoidal in shape it is legitimate to imagine that they are distributed without definite arrangement in the singly-refracting liquid phase, much as when a lot of sticks of firewood are thrown together. As the kinetic energy of such a heterogeneous mass of molecules diminishes by a fall in temperature. it is natural to imagine that swarms of molecules in parallel arrangement may be formed and constitute the doubly-refracting liquid. Bose has thrown quite a remarkable light on this question by careful determinations of the heats of transition and the viscosity of anisaldazine.

The change, solid anisaldazine to doubly-refracting liquid, absorbs about 20 calories, which is a quite ordinary magnitude, but the change, doubly- to singly-refracting liquid, absorbs less than one calorie, a minute amount when compared with ordinary heats of liquefaction. The viscosity of the singly-refracting liquid increases normally as the temperature falls to the limit when turbidity sets in, and then diminishes very sharply to a minimum about two degrees below; as the temperature still falls the normal increase of viscosity is again established, but the viscosity never attains anything like the magnitude of that of the singly-refracting liquid. This peculiar behaviour constitutes the so-called "viscosity anomaly" and has been treated kinetically by Bose. If the anisaldazine molecule has the shape of an ellipsoid of rotation, Bose shows that the viscosity ratio of doubly- and singly-refracting liquid can theoretically be as low as 0·67; if the molecule has the shape of a triaxial ellipsoid this ratio may fall even lower. The observed ratio is 0·65 for anisaldazine, and in further support of the swarm theory is the fact that the change, singly- to doubly-refracting liquid, is accompanied by a notable increase in density.

Each swarm of parallel-placed molecules should exhibit the symmetry of a figure of rotation; the wave surface of light in the swarm should be the double ellipsoid of rotation and sphere characteristic of all uniaxial substances. In accordance with this, all doubly-refracting liquids are uniaxial. So long as the dimensions of the swarm are greater than the wave-length of light, the mass should appear turbid; as the swarms diminish in size with rise in temperature, they would become of less magnitude than the wave-length as the liquid becomes singly-refracting. The swarm itself should, of course, be clear and show no turbidity; Bose showed that a layer of doubly-refracting liquid anisaldazine 4 m.m. thick is cleared by the application of a magnetic field of a few thousand Gauss units when viewed along the direction of the lines of force. With most doubly-refracting liquids the optic axis lies normal to the face of the miscroscope slide, but on setting up a transverse magnetic field the optic axis is deflected slowly towards the direction parallel to the lines of force.

One observation appears to be in disaccord with the swarm theory. More than one doubly-refracting liquid phase sometimes exists; thus, cholesteryl caprinate forms three doubly-refracting liquid phases. [Shown with cholesteryl caprinate.]

THE FRENCH METALLURGICAL INDUSTRY

The number of blast furnaces alight has risen from 88 in May to 99 on June 1, whilst 74 are ready to be lit, and 46 are being built or repaired. This greater activity corresponds with the increase in the output of pig-iron from 350,485 metric tons in April to 393,428 t. in May and of steel from 365,791 t. to 399,249 t. during the same period.

It is reported that one difficulty hindering the application of the Basset process for the production of steel directly from the ore has been solved. This difficulty was presented by the lining of the furnace, but it now appears that the use of the rotary furnace has been abandoned, a fixed furnace of the Martin type being used instead.

RECENT RESEARCHES ON THE CAUSATION OF RICKETS

By PROF. J. C. DRUMMOND, D.Sc.

Some few years ago the Medical Research Council, then the Medical Research Committee, decided to initiate an exhaustive investigation into the etiology of rickets, in view of the fact that this previously much neglected disease is responsible for untold damage and loss of child life, particularly in our large cities. At the outset of the series of investigations made with their assistance there were very many theories of the origin of the disease, but, broadly speaking, they could be grouped into three classes, according to whether the causative factor was held to be an infection, unsatisfactory hygienic environment, or some defective dietary condition.

The pioneer researches of Mellanby (Medical Research Council, Special Report No. 61, 1921) demonstrated that a condition closely resembling infantile rickets could be produced experimentally in young dogs by feeding them on ill-balanced diets, in which there was a deficiency of an organic substance showing similar properties and distribution in foodstuffs to the so-called vitamin A. or fat soluble A. His experiments appeared to be well controlled, but his conclusions were vigorously attacked by Findlay, Noël Paton and other workers of the Glasgow School, who strongly supported the view that defective hygienic surroundings, lack of sunlight and exercise, with perhaps an associated specific infection, were responsible for the disease (Findlay and Ferguson, M.R.C., Special Report No. 20, 1918, and later publications). For a time it was difficult to reconcile the statements of the experimentalists of the two schools, but with the discovery by Huldschinsky (*Deut. Med. Woch.*, 1919, **45**, 712) that the short wave length radiations of the mercury vapour lamp would cure bone lesions in rickets in children, and more particularly with the observations of Hess and Unger (*Proc. Soc. Exper. Biol. Med.*, 1921, **18**, 298) that cures of experimental rickets could be similarly brought about by sunlight, it was possible to foresee how the two lines of thought might converge.

Meanwhile, two further important studies of rickets were published under the auspices of the Medical Research Council. One by Korenchevsky (M.R.C., Special Report No. 71, 1922) gave, in addition to an excellent review of previous studies, the results of his own experimental work, mainly on rats, whilst the second, by Mann, (M.R.C., Special Report, No. 68, 1922) was a report of close clinical observation of a large number of cases of rickets in London. Both investigators were led by their observations to support the dietetic theory, and Korenchevsky, in particular, held that the most important factor in the causation of the disease was a deficient supply of an as yet unidentified organic factor present in cod-liver and certain other oils.

Quite recently there has been published a further report which constitutes a most striking contribution to our knowledge of rickets. This is the report by Miss Chick and her colleagues from the Lister Institute, who were sent under the auspices of that Institution and the Medical Research Council to Vienna in 1920, in order to make a close study of rickets, which at that time was ravaging the infant population of Central Europe. (Medical Research Council, Special Report, No. 77, 1923. H.M. Stationery Office. 7s. 6d.). One of the most striking features of this report is the preface written by Professor Clemens Pirquet, Director of the Kinderklinik of the University of Vienna, who provided the facilities for the work and gave valuable assistance. Two quotations from his remarks are given below.

"The results of the first two years' work of our British colleagues showed me no reason for changing my opinion (*i.e.*, that rickets was an infectious disease, to which children were prone as the result of defective hygiene, defective food, etc.). The minute and conscientious observations carried out by them on a large number of individual cases led to no clear conclusion, but the third year of their work shed new light upon the subject."

After reviewing briefly the nature of the crucial experiments made and their results he adds :—

"With this the chain of evidence appears to me to be complete that animal experiments upon rickets are applicable also to man, that rickets is a disease of nutrition, and that deficiency of fat-soluble vitamins in diet is an essential cause of the disease."

Miss Chick and her co-workers have found that the action of sunlight, or other source of short wave length radiation, is apparently not to replace the vitamins, but to enable the animal organisms to economise its supply of that substance. In other words, an animal will require a greater amount of the organic factor or factors present in cod-liver oil to protect it against the onset of rickets if it is maintained under conditions of bad lighting. It is now possible, therefore, to see a reconciliation between the two schools of thought. There can be no doubt that the chief causative factor of rickets is a deficient supply of the vitamins associated with certain oils, but primarily found in most green vegetables. If the supply of these accessory food factors is not optional then the unhygienic surroundings and bad lighting of slum dwellings may operate as a secondary factor just to turn the scale so that the disease appears.

Part 4, sections 3 and 4 of this last report contain an account of some very striking experiments by two of the Lister Institute team, Miss E. M. Hume and Dr. H. Henderson Smith. In attempting to solve the effect which short wave length radiations have in economising or activating the vitamin A, they found that exposure of the animal to the rays was not necessary, but that placing them in jars containing air which had been previously irradiated had the same effect. Apparently the active agent in the irradiated air is not ozone, for exposure to this gas had no beneficial action.

Possibly the authors will turn their attention to certain oxides of nitrogen, which are produced under these conditions, and which Prof. B. Moore held to be the beneficial agents of seaside air so frequently termed "ozone."

All will await with the greatest interest the discovery of the nature of the two chemical substances which play such important parts in the normal calcification of bone ; on the one hand the organic vitamin in cod-liver oil, and on the other the presumably inorganic factor present in irradiated air.

The series of reports outlined in this short review have thrown a clear light on the etiology of that dread disease rickets, and it may well be a source of pride that British workers have played so great a part in solving the problem and rendering it possible for the scourge of the "Englische Krankheit" to be wiped out.

SAFEGUARDING OF INDUSTRIES ACT

FORMALDEHYDE

The following is the decision recently issued by the Referee on the complaint made by the Chemical Merchants' and Users' National Vigilance Committee and opposed by the Board of Trade, May and Baker, Ltd., and Howard and Sons, Ltd. :—

The question in this reference is whether formaldehyde is properly included in the list of articles dutiable under the Act. The case has troubled me a good deal because it raised three distinct questions as to every one of which I was asked to depart from principles I had already laid down for my guidance. I do not say that I regard myself as bound by what I have said before. If I am satisfied in the light of further evidence that what I have said should be modified. I will be quite ready to act on that conviction. But unless and until I am satisfied that the evidence given and accepted by me in earlier cases was wrong, or that I misunderstood it, I propose to adhere to the lines I have laid down.

It is said by the Board of Trade that the inclusion in the list of formaldehyde is justified—1. Because it is an analytical reagent. 2. Because it is a synthetic organic chemical. 3. Because it is a fine chemical.

(1) It is very difficult to say when a chemical which has a use as an analytical reagent is within the Act, but of this I have no doubt,

that unless a chemical compound has a real and substantial use as distinct from a nominal or occasional use as an analytical reagent it ought not to be included as such in the list. I am satisfied that the use of formaldehyde as an analytical reagent is too trifling to justify its inclusion in the list as an analytical reagent.

(2) I think that a good deal of confusion may arise unless one bears in mind that neither chemists nor books speak of synthetic chemicals. The expressions "synthetic perfumes" and "synthetic dyestuff intermediates" are doubtless in common use, but I think that the word "synthetic" is used quite loosely in the former case, and I am told by Sir Arthur Colefax and Mr. Parry that the expression "synthetic intermediates" has a special meaning referring to bodies from which synthetic dyestuffs can be obtained. The use of the word in this connexion, therefore, throws but little light upon its meaning in the Act.

Various writers have defined the word "synthesis." The word describes certain methods of production of chemical compounds. I am asked by the opponents to say that if a chemical can be produced synthetically, that chemical is a synthetic chemical without regard to the question whether in any particular case the substance has been, in fact, so produced. In my opinion, that is not the meaning of the Act. I think that the expression "synthetic organic chemical" means such chemicals as have in fact been produced synthetically. The results of the contrary view, if logically worked out, are so startling that I shrink from its adoption.

In my opinion the question to be determined in each particular case resolves itself into this: Has the substance on the importation of which it is claimed that duty is payable, in fact, been produced synthetically?

It is, of course, common ground that the synthesis of an organic chemical includes its building up (to use Thorpe's expression) or its formation (to use Richter's expression) from its elements. It is equally clear that synthesis includes the "building up" or "the formation" from such carbon derivatives as can be obtained from the elements. But if the carbon derivative actually employed in the latter case as the raw material is one which, although it could be, has not, in fact, been produced synthetically, it is contended, at least, I understand that it is contended, that the resulting compound is synthetically produced without regard to the nature or character of the further building up or formation from that raw material.

I am assisted in the decision of this point by the fact that there is no evidence to support the contention.

Dr. Ormandy and Mr. Parry are at one on the point. To quote the former, "the raw material must be one which could in case of necessity be produced through all the steps from its elements, and the further step must itself be synthetic." I accept that view.

There then remains to be decided the question whether the step taken, *namely*, the oxidation of methyl alcohol in the presence of a catalyst is truly described as synthesis. By this oxidation the methyl alcohol loses two atoms of hydrogen. Does this step partake of the nature of synthesis?

In two earlier cases great stress has been made upon the contention that the essence of synthesis was a building up, or at any rate, a bringing or placing together. The truth of that contention was one of the main issues in the camphor case. I quote the following passage from the opening remarks of Sir Arthur Colefax; "The Board of Trade are actually driven to this incredible position. Synthesis I have always until now understood merely as a matter of definition involving, adding something to or putting something together. But they are driven by the logic of their argument to this truly remarkable position, that synthesis is no longer to be putting two things together, but it is to be actually applied to a case where you take something away. It is a most remarkable use of the word synthesis, and certainly I should have thought that nobody has ever held it." And, later, he put to his main witness the question, "mere oxidation would never be talked of as building up." He also asked the question in argument, "Where is the case that they can point to in which you can find general acceptance of the term "synthesis" where the change does not involve an addition of a carbon atom?" I quote these passages to show how clearly the contention was raised on the one side in that case. On the other side, the Board of Trade submitted that the meaning of a "synthetic organic chemical" was "a chemical produced by controlled processes resulting in molecular changes of any kind." Dr. Forster, called for the Board of Trade, objected to the expression "building up," and argued that the true meaning was "placing together." He agreed that the generally understood meaning of synthesis was the bringing together of the component elements. He agreed that by the vast number of chemists to-day the bringing together of elements or radicles to form a more complicated body was their understanding of the term. On the evidence given in that case and on the arguments of Sir Arthur Colefax I accepted the view that synthesis, as generally understood, involved the bringing together of elements or radicles to form a more complicated body. I definitely rejected the contention that synthesis, as generally understood, included any molecular change so long as it was produced by controlled processes. I thought, and still think, that it is my duty to give to the words their commonly accepted meaning. Doubtless many chemists hold a different view. It is obvious that I cannot decide that the steps necessary for the formation of formaldehyde from methyl alcohol are synthetic without ignoring or reversing the view I took in the camphor case. It is to be noticed that no evidence was called by the Board of Trade or those supporting their view as to the meaning of " synthetic " or as to whether formaldehyde was or was not a synthetic chemical. Dr. Ormandy dealt with it only in cross-examination. He did not take quite the same view as Dr. Forster. He expressed the opinion that an operation was synthetic if it was a controlled reaction and if it gave proper yields—an entirely new suggestion. It is sufficient to say that no evidence has been given which satisfies me that the view I took in the camphor case was wrong. Incidentally, that view is entirely consistent with the evidence given in the calcium-carbide case.

(3) I frankly admit that I should like to be able to decide that formaldehyde is a fine chemical. My difficulty is that I cannot find any ground upon which I can do so consistently with what I believe to be the true principles applicable.

It is quite clear on the evidence that this substance has not been commonly regarded as a fine chemical.

The *Chemist and Druggist* definitely treated it as heavy; it appeared as heavy in Haywith and Hart's advertisements. Several lists were put in, in which formaldehyde was classified as " technical " or " general " as opposed to " fine." This may not amount to very much, but, on the other hand, not a single instance could be given of formaldehyde being called a fine chemical, or being classified as such before the Act of Parliament. An American paper, of 1923, was produced in which it was classified as " fine," and the list of fine British chemicals published in 1922 includes it. Dr. Ormandy was not asked about it. Mr. Allen, called by the opponents, could only say that he did not regard it as a heavy chemical, and that he did not understand the meaning of " fine."

No one was called from any of the big fine-chemical manufacturers. Two or three gentlemen were called who expressed the opinion that it was a fine chemical, but there was not any evidence at all that when this Act was passed formaldehyde had been regarded as a fine chemical in any branch of the trade.

According to my decision in the tartaric-acid case, this finding ought to settle the case; but I think that one is driven to the same conclusion by a consideration of the other circumstances said to be relevant.

This chemical is not a pharmaceutical chemical. The opponents disclaimed any intention of putting it forward as such. It is an industrial chemical produced on a fairly large scale—a scale very large for a fine chemical.

There is no doubt that most of the witnesses that have given evidence before me regard an industrial chemical used on a substantial scale as something very different from a fine chemical. Even representatives of May and Baker and Howards, manufacturers of fine chemicals on a very large scale, take the same view.

A special plant is necessary for its production. It is handled in quantities somewhat big for a fine chemical.

On the other hand, it is said that the formaldehyde on the market is of great purity, and that its manufacture involves continuous scientific control. One has only to re-read the evidence in the earlier cases to see (1) that the degree of purity does not help very much, and (2) that the scientific control there described as necessary to stamp the product as a fine chemical was a control of highly trained chemists as opposed to the skilled control of persons trained *ad hoc*, with the result that the cost of that control was high relatively to the total cost.

I am not at all satisfied that the skill required to produce formaldehyde is anything more than the skill of men taught and trained for the particular purpose, and Mr. Romanes said in his evidence that if you worked out the cost per ton of the scientific supervision you would find it very small.

I do not think that the description of the fine-chemical group, group 6 of the (Association of) British Chemical Manufacturers, covers this substance.

The case is one of those border-line cases upon which opinion will necessarily differ, but dealing with it as best I can in the evidence given, I find that the complainants have made out their case and that I must award that formaldehyde be excluded from the list.

ROCHELLE SALT

The Referee's award (dated August 16) on the complaint relating to Rochelle salt runs as follows :—

In my opinion no case has been made out for taking Rochelle salt out of the list.

The Rochelle salt of commerce is a pharmaceutical chemical. It has also a well-recognised use as an analytical reagent. It has practically no industrial use.

I am inclined to think that the use as an analytical reagent in itself justifies the inclusion of Rochelle salt in the list, but I do not decide the case on that ground. Mr. Kenneth Swan's contentions may possibly require very careful consideration in some future case.

I decide this case on the ground that there is no evidence to justify me in saying that the Board of Trade was wrong in including Rochelle salt in the list as a fine chemical.

The fact that the chemical is used only in pharmacy and as a reagent raises a strong presumption that the trade would regard it as a fine chemical. Mr. Howard said that it was known in the trade as a fine chemical. Mr. Blenkinsop and others gave similar evidence. There was no trade evidence to the contrary.

In my opinion there is no evidence that Rochelle salt is wrongly included in the list, and I award that the complaint fails.

FORTHCOMING EVENTS

Sept. 10–13. The Institute of Metals. Annual Meeting at Manchester. *Second Annual Autumn Lecture.* "The Use of Non-Ferrous Metals in Engineering," by Lieut.-Col. Sir Henry Fowler, K.B.E., at 8 p.m., Sept. 10. "The Cause of Red Stains on Sheet Brass," by E. A. Bolton. "Note on 'Brinell Hardness Numbers,'" by H. W. Brownsdon. "The Behaviour of Metals under Compressive Stresses," by H. I. Coe. "On the Measurement of the Change of Volume in Metals during Solidification," by Hikozo Endo. "The Electrochemical Character of Corrosion," by U. R. Evans. "The Constitution and Age-Hardening of the Quarternary Alloys of Aluminium, Copper, Magnesium and Magnesium Silicide," by Marie Gayler. "Investigation of the Effects of Impurities on Copper (Part I—The Effect of Oxygen on Copper)," by D. Hanson, C. Maryatt, and G. W. Ford. "Experiments with some Copper Wire; Cohesion a Function of both Temperature and Cold-work," by D. H. Ingall. "The Effect of Small Quantities of Nickel upon High-grade Bearing Metal," by A. H. Mundey and C. C. Bissett. "Stereotyping," by A. H. Mundey and J. Cartland. "Hardness Tests on Crystals of Aluminium," by H. M. O'Neill. "A Dilatometric Study of the Transformations and Thermal Treatment of Light Alloys of Aluminium," by A. M. Portevin and P. Chevenard. "Effects of Rate of Cooling on the Density and Composition of Metals and Alloys," by R. C. Reader. "Crystallisation Effect on Galvanised Iron Sheets," by E. L. Rhead and J. D. Hannah. "Equilibrium in the System Gold-Zinc (based on Investigations of Electrical Conductivity at High Temperatures)," by Prof. P. Soldau.

Sept. 12–19. The British Association for the Advancement of Science. Ninety-first Annual Meeting, to be held at Liverpool. The President, Sir E. Rutherford, F.R.S., in his inaugural address, will deal with "The Electrical Structure of Matter."

Sept. 17–18. The Iron and Steel Institute. Autumn Meeting, to be held at Milan, in the Chamber of Commerce, commencing each day at 9.30 a.m. At the conclusion of the meeting visits have been arranged to Florence. Rome. Piombino, Leghorn, Genoa, and Turin.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

MANCHESTER SECTION

The programme of the Manchester Section for next Session is almost complete and commences on October 5 with an address from the new chairman of the Section, Dr. H. Levinstein, entitled "Recent Progress in Chemistry"; the meeting on November 2 is the usual joint meeting with the Local Sections of the Institute of Chemistry, Society of Dyers and Colourists and with the Manchester Literary and Philosophical Society. This year it is the turn of the Society of Dyers and Colourists to choose a lecturer, and they have invited Prof. W. D. Treadwell, professor of analytical chemistry at the Eidgenössische Technische Hochschule, Zurich, who will give a paper on "Electrometric Methods in Analytical Chemistry." On December 7, Dr. T. Callan and N. Strafford will read a paper on "The Analysis of Rubber Vulcanising Accelerators", to be followed on the same evening, it is hoped, by a paper from a member of the Institution of Rubber Industry. The January meeting will be held on Friday, the 11th, and two papers will be presented—viz., "Fullers Earth," by A. Brittain, and "Fractional Distillation," by C. Elliott. The fifth meeting on February 1, will be addressed by Dr. Ernest F. Ehrhardt, who has chosen for his subject, "Reminiscences of Dr. Caro." Prof. F. Gowland-Hopkins, F.R.S., of Cambridge, has promised to give an address on

March 7, the provisional title being "Some Chemical Qualities of the Living Cell" (it is possible that this and, indeed, any of the above titles may be changed). The meeting of April 4 will include a paper by Prof. F. L. Pyman, F.R.S., on the "Tautomerism of Amidines." Other papers are promised, and the Session will probably require further dates. There is a likelihood of another joint meeting with the Liverpool Section at a date to be announced and members are asked to book the date, November 23, for the Annual Dinner of the Section, which will be held at the Queen's Hotel, Manchester. L. Guy Radcliffe

BRITISH ENGINEERING STANDARDS ASSOCIATION

The fifth annual meeting was held on July 12 at the Institution of Mechanical Engineers. The Chairman, Sir A. Denny, in reviewing the year's work, stated that the Association was faced with a deficit of some £1700 and hoped that both the Government and Industry would help to put the finances of the Association on a more stable basis. The national character of the work of the Association, devoted to simplification and the promotion of economy in our engineering and allied industries, was too well known to need comment. The Association was not a profit-making body; and it had nothing to gain from, but much to give to, industry. The continually increasing volume of work which the Association had to deal with necessitated more generous financial support than was now given. Neither the Government nor industry as a whole appeared fully to appreciate the value of the work done voluntarily by the 2000 engineers constituting the Association.

On July 3–6, a second unofficial conference of secretaries of the various standardising bodies was held in Zurich, thirteen different countries being represented—viz: Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Norway, Sweden, Switzerland and United States. When the first conference was held in London in 1921, the secretaries of seven standardising organisations were present. Reports were presented on the progress of the standardisation movement in various countries and a general discussion took place on organisation, methods of working, the practical application of the standards, the extent to which international collaboration is now taking place and the possibilities of making it more effective. Considerable progress appears to have been made during the past two years towards closer international collaboration and a number of questions of importance to various branches of industry were discussed. The recommendations made by the conference will be placed before the national organisations.

CORRESPONDENCE

A SUGGESTION

Sir,—Two considerations incite me to send this letter—one is the fear that we may one day have a fearful accident on a tube railway, and another is anxiety about the coming winter, when many more people are likely to lack work. The fear about the tube railways is that in case of fire in a tube there is every condition for a really serious accident, as nearly all the fittings above the frames of the cars consist of inflammable material in a state of dryness calculated to spread fire very rapidly. Then nearly all the woods and many other materials employed in the construction of these carriages are imported, some more or less ready for use.

I should like to suggest that nearly all the parts and fittings of railway carriages (walls, partitions, roof, flooring, seats, doors) might be made of metal. In conjunction with steel this would be a good opportunity to use aluminium and its alloys, rustless iron alloys, etc.

The objection that metals are noisy can easily be overcome. For example, doors, partitions and the like can be constructed with double walls of thin metal and the space between filled with material such as slag wool or asbestos, which are most excellent sound deadeners as well as being non-inflammable and bad conductors of heat. All the materials I have mentioned are produced in this country. Their application in the direction I have roughly indicated would give employment to many artisans, not merely those who only "fetch and carry" or wield the crowbar. I see no reason why the stuffy, microbe-colonised seats in public conveyances should not be replaced by metal wire-gauze arrangements which might, if necessary, be covered with one of the usual covering materials. It needs but little imagination to apply steel where some strength is needed, and aluminium, or the like, in places where no great strain comes. All these metals can be painted or enamelled as cunningly and æsthetically as carriages usually are. Doors can be constructed of a steel frame with aluminium and glass fillings and deadened against the classic bang of the railway official, as well or better than the expensive timber construction now used.

All this would be safe against fire, and *home made*. Some part of what I have said about "carriages" applies to doors, window panes and other fittings in houses. A considerable amount of fitted woodwork is imported ready made from abroad. I see no reason why a house door should not consist of a steel frame with light-metal panels padded or lined or filled, as the case may be, with some substance for the purpose before mentioned. Metal window frames would give us a chance to return to the more sanitary, so-called Tudor windows, which open outwards like a door and let air into the house.—I am, Sir, etc., W. R. Hodgkinson

Eastbourne, August 19, 1923

THE LATIN WORKS OF GEBER

Sir,—I think it will be admitted that Prof. J. R. Partington has adequately proved his point, and that he has shown that the spectre which Prof. Lippmann challenged him to produce has a distinctly material existence. Prof. Partington's promised article on the Latin works of Geber will be awaited with interest, for, as he has already remarked, the identity of Geber is one of the most important problems in the history of chemistry.

As I am responsible for suggesting that the old identification of Geber with Jabir ibn Hayyan has a good deal to be said for it, perhaps I may be allowed to make one or two observations. In the first place, I believe that the Latin works of Geber show unmistakable signs of an Arabic origin, though they may not be literal translations. This view I have expressed previously (*Nature*, February 10, 1923). It was therefore with considerable pleasure that I noted that Prof. Julius Ruska, in a review of Darmstaedter's *Die Alchemie des Geber*, which is to appear in the next number of *Isis* (and of which Dr. Sarton, editor of *Isis*, was good enough to send me an advance proof), expressed the opinion that, whilst the Latin works are not translations from the Arabic, the author "muss arabische Quellen gekannt und direkt oder indirekt benützt haben. Dies erhallt nicht nur aus dem Gesamtinhalt, sondern auch aus der Disposition der Schriften und aus einzelnen Wendungen und Fachausdrücken." One may also note in this connexion that Prof. H. E. Stapleton (Mem. Asiat. Soc. Bengal, 1905) concluded that "the contents of the Summa were derived from previously existing Arabic works on Alchemy."

As to E. Meyer's statement (quoted by Prof. Partington) that "it is just possible that neither Gabir nor Chalid ben Jazid ever lived or wrote," one may remark that all the Arabic authorities agree in assigning Jabir to the eighth century A.D., that Al-Nadim (10th century) used Jabir's own catalogue of his writings in the preparation of his encyclopædia, that some 80 books ascribed to Jabir (most of them mentioned by Al-Nadim) are still extant, and finally that in the *Kitab al-Aghani*, the "Register of the Arabs," compiled by Abu'l-Faraj of Ispahan (died 967 A.D.), five or six pages are devoted to the life of Khalid ibn Yazid, casual mention being made of the fact that "he busied himself with the search for Al-Kimia" (*i.e.*, the philosophers' stone).

The recent discussions have at least conclusively proved that, so far from "Geber's" writings representing European advances in chemistry made in the twelfth or thirteenth centuries, they were merely the means of introducing to many European chemists the chief knowledge of the chemists of Islam. Prof. Ruska himself says: "Man wird erstaunt sein, wie viel von technischen Einrichtungen, die der lateinische Geber beschreibt, schon dort und bei andern im Orient lebenden Vertretern der 'grossen Kunst' vorhanden war."

The whole problem is gradually resolving itself, and in the light of information gained by attacks from both the Latin and Arabic sides we may reasonably hope that a satisfactory solution will be found at no very distant date.—I am, Sir, etc., E. J. Holmyard

Clifton College
August 20, 1923

HAFNIUM OR CELTIUM?

Sir,—I have read Prof. Urbain's article in the current number on the above subject with considerable interest, and mingled feelings of disgust and amusement. Surely to Science the importance lies in the facts, the honour of priority being quite subsidiary. Contemporaries never get their due, and posterity will do as Prof. Urbain recalls was done in the Crookes-Lamy controversy. Perhaps it does not strike the authors that to the public such polemics are childish and hardly likely to increase the appeal now so widely being made. After all, the History of Science is strewn with instances and a hundred, two hundred . . . . years hence what matter whose name is linked with milligrams of material, so long as that is identified correctly?

It can only be regretted that the attitude is foreign to no branch of Science: Mr. Johnstone's plea for a sense of humour in the same number of *Chemistry and Industry* might well be emphasised.—I am, Sir, etc.,

A Hundred-Thousandth of the
Chemical Brigade

August 14, 1923

* * *

In our issue of July 27 we published a review of a book entitled, "Textile Chemistry," by F. J. Cooper, of the Blackburn Technical College, in which Mr. Cooper considers that it is implied that the author had attributed to Mercer the discovery of the lustring of cotton and that he was ignorant of the fact that this was a later development of the process. This implication is untrue. In fact, the author stated as follows:—

"Unfortunately mercerized cotton was not a commercial success in Mercer's lifetime, and in fact made very little progress until another property regarding it was discovered some 30 years later. Since then it has increased enormously in popularity.

"This important characteristic is produced by stretching the cotton during or after immersion in the alkali and keeping it so during the washing process. The fibre is thus prevented from contracting, with the result that an external lustre is produced."

If such an implication as mentioned above was made we regret it and we offer to Mr. Cooper our sincere apologies for its publication.

B

PERSONALIA

Mr. J. A. S. Ritson, senior inspector of mines in the Cardiff district, has been appointed to succeed Prof. Granville Poole (who has accepted a chair at Armstrong College, Newcastle-on-Tyne) as professor of mining in the University of Leeds.

Prof. E. Anderson, of the University, Nebraska, has become head of the chemistry department at the University of Arizona, and J. H. Schmidt has resigned his instructorship in organic chemistry at the University of Wisconsin to become research chemist to the Redmanol Chemical Products Co., Chicago.

Monsieur Binder, vice-president of the Société de Chimie Industrielle, has been appointed Chevalier of the Legion of Honour.

Prof. The Svedberg, who has been lecturing and directing research work on colloid chemistry during the summer session at the University of Wisconsin, has been awarded the degree of D.Sc. *honoris causa* by that University.

Dr. W. Schumann, Director of the Institute for Technical Physics of the University of Jena, has been appointed professor of electrotechnology in the Technical *Hochschule* of Munich.

* * *

From Paris the death is announced of Monsieur E. Agache Kuhlmann, president of the Etablissements Kuhlmann. M. Kuhlmann was responsible not only for the expansion of the firm of chemical manufacturers that bears his name, but also for the development of the textile factories of Agache Fils.

NEWS AND NOTES

SOUTH AFRICA

Reported Discovery of Platinum in the Transvaal

A correspondent writing in *The Times*, of August 16, announces that the discovery of platinum is reported from the Waterberg district of the Transvaal. A reef has been traced for 30 miles, and samples have been obtained which are said to show 46 per cent. of platinum and payable gold.

The Portland Cement Industry

The four portland cement factories in South Africa have a capacity of 4,250,000 bags (1 bag=188 lb.) or 2,125,000 casks per annum, but production during the past year has been reduced by one-half, owing to the poor demand. The industry is stated to be suffering from foreign competition, as ocean freights are low compared with the heavy rail rates in South Africa. Prices of South African cement, however, have been reduced appreciably during the past year, and compare favourably with prevailing foreign rates on a f.o.b. works basis. In 1922 the import of cement was 248,376 casks, chiefly from Great Britain, Belgium, Norway and Denmark.—(*U.S. Com. Rep., June* 25, 1923.)

FRANCE

Société de Chimie Industrielle

The Annual Meeting of the French Society will be held in Paris from October 21 to 27, when papers covering the various fields of applied chemistry will be read and visits paid to various factories, etc. It will be remembered that during the Annual Meeting of the British Society in Cambridge, an invitation was extended by Monsieur Paul Kestner to British delegates to attend the congress in Paris.

AUSTRALIA

Eucalyptus Oil as a Motor Fuel

According to the *Oil and Colour Trades Journal* (August 18), Capt. C. M. Dyer claims that eucalyptus oil can be used as a fuel for petrol engines. Mileage tests gave the following results :—gasoline, 24 miles per gallon ; gasoline 50 per cent., eucalyptus 50 per cent., 28 miles per gall. ; eucalyptus oil alone, 28 miles per gall. It is claimed that the oil acts as a decarbonising agent, but priming is necessary, as a start from cold cannot be obtained. It is reported that the Australian Government may take up the question. Distillation of eucalyptus oil is very simple, the main difficulty being to find labour for picking the leaves. The yield varies up to 35 lb. of oil per 1000 lb. of leaf.

GENERAL

Donation of £15,000 to the Imperial College of Science

The Clothworkers' Company of the City of London has offered an annual contribution of £3000 for the period 1923-27 to the Imperial College of Science and Technology, South Kensington, to be applied towards the maintenance and development of the City and Guilds (Engineering) College, one of the three constituents of the Imperial College of Science. This gift is supplemental to the £85,000 voted some years ago by the Goldsmiths' Company to enable the College to extend its buildings, and is distinct from the annual vote of £5000 from the City and Guilds of London Institute which has been paid to the Imperial College since the Charter was granted some 15 years ago, and applied to the City and Guilds (Engineering) College. The gift is a pleasing indication of the value attached to research and teaching in science as related to industry.

Chilean Nitrate Industry

The Chilean nitrate industry has almost completely recovered from the slump of 1921, for sales effected during the 9 months ending March 31 totalled 2,185,108 metric tons or only 15 per cent. less than the quantity sold in the same period of prosperous war years. The number of plants working increased from 59 in March to 62 in April. Stocks are being steadily reduced throughout the world, and exports from Chile have increased greatly, approximately 50 per cent. of recent shipments going to the United States.—(*U.S. Com. Rep., June* 18 *and* 25, 1923.)

REVIEWS

Industrial Hygiene and Medicine. *By* E. W. Hope, O.B.E., M.D., D.Sc., *in collaboration with* W. Hanna, M.A., M.D., D.P.H. *and* C. O. Stallybrass, M.D., D.P.H. *Pp.* viii+766. *London: Baillière, Tindall and Cox*, 1923. *Price* 25*s.*

The appearance of a volume dealing with the whole scope of industrial hygiene is such a rare event in this country, that not a little interest is aroused by the publication of this volume of over 750 pages under the joint authorship of Dr. E. W. Hope and two of his colleagues on the public health staff of the City and Port of Liverpool. The aim which the authors had in view is stated in the preface, " that British and Colonial, American and Continental experience and progress should again be presented and summarised for the student in a single volume. The book is primarily intended for the medical profession, but it is hoped that others engaged in the various aspects of industrial hygiene and welfare will find it of value."

The book is arranged in eleven chapters, the first three being devoted to general aspects of the history of legislation in industry, vital statistics and the application of the principles of environmental and community hygiene.

Under " Vital Statistics of Occupation " a collection of data is given with the general effect of showing the fallacies in present statistical methods when applied to industrial conditions. The need for definite lines of study and tabulation is indicated, but no very practical suggestions are put forward.

Under industrial poisonings, amongst others, the important subject of lead poisoning is discussed in its various sources and manifestations. The reviewer does not agree that " of all the individual precautions to be adopted, those relating to personal hygiene are by far the most important. Very little trouble is required and the dangers to health and life can easily be avoided." On the contrary, constant vigilance on the part of the employer as to the efficiency of the plant and unremitting care on the part of the worker regarding cleanliness and the avoidance of dust and fume inhalation are necessary to achieve this end. The danger of poisoning from lead fume in oxy-acetylene burning in ship-breaking is important and difficult to deal with, though here it is referred to only in a footnote.

" Dust as a cause of disease " receives extensive treatment in a chapter of 80 pages. The methods of investigating the dust content of air, and the character of the particles in animal, vegetable and mineral dusts are described and an outline of the physiological defences and pathological effects of various kinds of dust is given. The dusts arising in different industrial processes and the appliances devised to remove them are described. No mention is made of Owens' dust-counter amongst the methods of dust collecting; it certainly does not come within the somewhat sweeping statement, applied to the impaction method, that it " apparently fails to catch most of the very fine particles which are especially dangerous." The disease known as " silicosis," has given to it the alternative name, " dust phthisis "—a term which has no specific meaning and certainly does not mean " silicosis." The opening sentence in the paragraph :—" The development of a fibrosis of the lung is due to mineral dust containing silica," requires modification, as fibrosis may be produced by dusts other than silica, and even independently of dust. Speaking of grinding of metal articles, " The use of ' wet methods,' where possible, is advocated "; some of the worst processes to-day are " wet methods." The term " phthisis " is used freely in this chapter and coming from Medical Officers of Health this is to be regretted, as it may stay the abolition of a term which has played havoc with health statistics in the past.

In the chapter on industrial infections a full description is given of the Government Disinfecting Station at Liverpool, as well as a useful description of anthrax as it occurs in industry and extracts from existing Regulations under the Factory and Workshop Acts relating to its occurrence in industry. Other infections are also dealt with, including tuberculosis, other respiratory diseases and some of the less common microbic and parasitic disorders. The importance of the inhalation of silica dust as a predisposing cause of tuberculosis is pointed out in various sections of the book, and attention is rightly called to the possible danger of stone dusting in coal mines in this connexion. The case of the tuberculous worker, handicapped, but able and willing for partial employment is set out in a convincing manner in this chapter.

In the chapter on diseases of the skin, a classification is made on the basis of the agents causing the injury, physical, chemical, irritant or poisonous. The ulcers caused by various chemical agents are described. The most important of these is the chrome ulcer produced by the chromates in the course of manufacture or in their use in the industries; reference is also made to the perforation of the nasal septum commonly seen in workers exposed to dust of chromates. The bichromates are also usually held responsible for skin affections in the dye industry, in French polishing, photo-engraving, etc. The effects on the skin of shale oil, coal tar, coal oils, pitch and soot are described and the serious epitheliomatous, or cancerous, ulceration is fully dealt with. A special section in this chapter deals with cancer and occupation, and data are set out which appear to indicate that arsenic plays an important part as a causative agent. In a table which shows the trades grouped according to the average comparative mortality figures for the two pericensual triennia 1890-1892 and 1900-1902, chimney sweeps reveal the highest mortality figure, 158, followed by gasworks service with 68·5, chemical trades with 68·0, and all occupied males 53·0.

The later portions of the book are devoted to discussions of industrial fatigue and allied conditions; industrial welfare, medical examinations and first-aid provisions in industry; the incidence, causation and prevention of accidents, and the provisions for workmen's compensation.

In three appendices are given references to British legislation affecting industrial hygiene, duties of local authorities under the Factory and Workshop Acts and duties of certifying factory surgeons.

The subject matter of the book is largely a compilation from many sources and a comprehensive bibliography is provided at the end of each chapter, which those desirous of following any of the subjects farther will find useful. It is here, indeed, that we think the chief merit of the work lies, in bringing within the compass of a single volume salient facts and references to authentic literature on a subject which has become so diverse in its application that specialisation is unavoidable where exhaustive treatment of any phase of it is aimed at. The book will fulfil a useful purpose as a work of reference and it is particularly well adapted for the use of Medical Officers of Health, from whose point of view the subject has been treated.

E. L. Middleton

Die Neueren Chemotherapeutischen Präparate aus der Chininreihe (Optochin, im besonderen Eukupin und Vuzin) und aus der Akridinreihe (Trypaflavin, Rivanol). *By* E. Laqueur, *assisted by* A. Grevenstuk, A. Sluyters *and* L. K. Wolff. *Pp.* 90. *Berlin: Julius Springer*, 1923. *Price, paper*, 3*s*.

The author has undertaken the praiseworthy task of sifting critically the mass of publications from pharmacologists and clinicians on the therapeutic value of the substances enumerated in the title. In all, five drugs are dealt with—namely, the quinine derivatives, optochin, eucupin and vuzin (respectively ethyl-, isoamyl-, and isooctyhydrocupreine), and the substituted acridines, flavine (trypaflavin) and rivanol (2 ethoxy-6.9-diaminoacridine). Though writing as a pharmacologist, he has set himself the task, outlined in the preface, of answering in regard to each of these preparations the simple but pertinent therapeutic questions: (1) Does it do the patient any good? (2) If so, what harm does it do him at the same time?

The author and his collaborators are of the opinion that "the opponents of chemotherapeutic research are unfortunately justified in complaining that excessive advertisement and personal enthusiasm ("einseitiger Enthusiasmus") make it very difficult for the most impartial observer to form an unbiassed judgment," and they wish to help those who desire to do so. In this undertaking they will surely earn the gratitude of the less "specialised" medical man, as well as that of the technical chemist or manufacturer who may be hesitating to put a new drug on the market, and to recommend it to the medical profession for use.

It has been frequently pointed out that in Germany the introduction of a new drug is greatly facilitated by the close collaboration of chemists, pharmacologists and clinicians, and that the appearance of a new chemical derivative in the laboratory, possessing potential therapeutic possibilities, is at once followed by a superabundance of pharmacological and clinical research. That this method rapidly brings to light useful drugs is undeniable, but it also leads to great confusion, due largely to the "personal enthusiasm" above referred to. This is by no means necessarily commercial in its origin.

The pamphlet is divided into three parts; in the first and second the quinine and acridine derivatives are respectively dealt with; the third section is devoted to a brief discussion of the question whether and in what degree experiments on antisepsis *in vitro* and *in vivo* can serve as a basis for therapeutics. The references to literature are (as the author admits) by no means complete, but the attempt has evidently been made to collect evidence calculated to throw light on the subject from all sides. For example, a considerable amount of space is given to the discussion of the English publications on Flavine, in particular to the work of Browning and collaborators, and the most interesting part of the book is decidedly that devoted to a critical survey of the practical antiseptic value in surgery of eucupin, vuzin and flavine on the basis of the publications reviewed. In the case of eucupin and vuzin, these are, unfortunately, nearly all German, but they are none the less highly controversial.

The author is loth to pronounce judgment of his own, and with the sole exception of optochin, the value of which as a local pneumococcicide and (if carefully administered) in pneumonia he regards as definitely established, the only result arrived at is "that the substance named can produce good results" if used in the right way.

It is evident, therefore, that the author does not belong to the "enthusiasts." Nevertheless, the conclusions are not discouraging to the chemo-therapeutical research worker, and it would seem that a critical work of this kind may also prove useful to him as a survey of the ground on which he stands, and from which a new line of exploration is to be mapped out.

J. W. Blagden

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Aug.* 16)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Algeria	Building materials, iron and steel sheets, galvanised sheets	205
,,	Sugar, petrol	206
,,	Copper sulphate, sulphur, fertilisers	207
British West Indies	Leather goods	D.O.T. 4254/ E.D. M.C.
do. (Trinidad)	Cement, galvanised iron	183
Bulgaria	Oil, varnish, lead, zinc	191
New Zealand	Cable wire	185
Norway	Pig iron, electrode scrap, paper	195
South Africa	White lead, oils, paints, varnishes	120
United States	Pig iron	213
Switzerland	Metals, machinery	202

TARIFF CUSTOMS EXCISE

Egypt.—Revised valuations have been issued for use in assessing import duties on various classes of iron and steel goods, with effect from November 15, 1923, or until denunciation.

France.—Waste of galvanised iron may be exported, until further notice, without previous authorisation.

Greece.—A decree, dated July 13, modifies the import duties on various goods. The modifications came into effect on July 15, and affect, *inter alia*, asphalt, iron and steel naphthalene, sulphide, sulphate, hyposulphite and hypochloride of soda, chloride of lime, chloride of manganese, celluloid, tinplate, aluminium, zinc, etc.

Italy.—Recent modifications in the "general" customs tariff affect sugar, oilseeds, artificial silk, iron and steel, various metals and their alloys, scientific instruments, ceramic products, glassware, mineral, resinous and tar oils, various chemicals and fertilisers.

SAFEGUARDING OF INDUSTRIES ACT, PART I

The Referee has decided that formaldehyde be excluded from the lists of articles dutiable under Part I of the Act, and the withdrawal will take place from August 20.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There is not much improvement in the market for chemical products and no great change for the better in the home trade can be anticipated until the holiday season is over. Export inquiries are comparatively good when the state of Europe and the world generally is taken into account. The most important change in price to be reported is a reduction of £2 per ton in manufacturers' prices for caustic soda.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d.—5s. per carboy d/d. Quiet in textile circles.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 7s. 6d. d/d.; Contract £10 7s. 6d. d/d. Quiet.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.–£5 per ton. Export demand continues good and manufacturers are in many cases fully sold for some time ahead.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.

Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	7½d.—1s. 3d. per lb.
Crimson	1s. 6d.—1s. 8½d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Cheaper at 10½d.—1s. 1d. per lb. Ample supplies now available.
Chromium Oxide	1s. 3d. per lb.
India Rubber Substitutes, White and Dark	5½d.—6¾d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

In sympathy with most trades, this market is now a little easier.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d.
Grey	£22 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8—£10 15s. per ton d/d, according to locality of market and type of charcoal. Demand easier.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2s. per gall. 24° Tw.
Red Liquor	1s 3d. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. „ „ 60% O.P Firm market as to price but demand quiet.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5–£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d. per lb. spot. 1s. 1½d. per lb. for forward delivery
Crude 60's	3s.—3s. 6d. per gall. Market firmer for early delivery.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 10d.—2s. 0d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price, no business.
Anthracene Oil—	
Strained	8¾d —11d. per gall. Supply short. Plenty of inquiries.
Unstrained	8½d.–10d. per gall. Market short.
Benzole—	Market uncertain. Prices doubtful.
Crude 65's	1s. 1d.—1s. 1½d. per gall.
Standard Motor	1s. 4d.—1s. 6½d. per gall. Business slack, abundant supplies.
Pure	1s. 9d.—1s. 11d. per gall.
Toluole—90%	1s. 8d.—1s. 10d. per gall. Not many inquiries. Easier.
Pure	2s. per gall. Not much inquiry.
Xylol	2s. 3d.—3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8d.—9d. per gall. Market steady.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—9d. per gall.
Solvent 90/160	1s. 5d. per gall. Quiet.
Solvent 90/190	1s. 4d.—1s. 7d. per gall. Market quiet.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business passing.
Whizzed or hot pressed	£11—£13 per ton. Quiet.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton.
Pitch, medium soft	135s.–145s. per ton. Autumn delivery. No buyers at present.
Pyridine—90/140	18s.—20s. per gall. Demand good.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 2d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Quiet.
m-Cresol 98/100%	2s 1d.—2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.

Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains exceptionally dull and orders continue to be very scarce owing to holidays and disturbed labour conditions.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	2s. 11d.—3s. per lb. for cwt. lots.
Acid, Benzoic	2s. 3d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 5½d.—1s. 6d. per lb., less 5%. Market weaker.
Acid, Gallic	3s. per lb. Down to 2s. 11d. for large quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d. per lb. Limited demand.
Acid, Tannic	3s. per lb. would now be accepted.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market weaker.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very weak.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	18s. per lb. now quoted. Prices for forward delivery considerably easier.
Benzonaphthol	4s. per lb.
Bismuth Salts	Good inquiry being met with. Prices unchanged.
Borax B.P.	£31—£33 per ton, carriage paid buyer's station.
Bromides	Position unchanged. Prices vary according to quantity and source.
Calcium Lactate	2s. 6d. per lb. for best makes. Better inquiry.
Chloral Hydrate	3s. 9d. per lb., duty paid.
Chloroform	2s. 2d. per lb. for cwt. lots. Very firm. Higher prices expected.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	Can now be imported free from duty. Spot supplies very scarce and prices erratic from £100—£110 per ton. Lower prices for forward delivery.
Guiacol Carbonate	8s. 6d. per lb. Spot supplies short.
Hexamine	3s. 9d. per lb. In fair supply on a quiet market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality and quantity.
Menthol	38s. per lb. spot, less 2½%. Slightly weaker.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 3d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid: Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9s., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 5d. per lb. Very slow.
Phenacetin	6s. per lb. Weaker tendency.
Phenazone	7s. per lb. In better demand, especially for small quantities.
Phenolphthalein	6s. 6d. per lb. Supplies still short.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 3d.—3s. 9d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	9½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 8d. per lb. Very quiet. Lower in value.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s. 3d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.

Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 6d. per lb., and Crystal at 2s. 7d. per lb. Market still very quiet.
Sod. Sulphite, anhydrous	£27 10s.—£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	15s. per lb. for cwt. lots of natural recryst.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. 9d. ,, ,,
Amyl Butyrate	7s. 6d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	2s. 9d. per lb.

Japanese	7s. 3d. ,, ,,
Petitgrain Oil	7s. 3d. ,, ,,

TRADE NOTES

Trade Information

Where to Buy Everything Chemical.—This useful guide to the principal sources of general and fine chemicals and plant, the July number of which has just been issued (London: S. Davis and Co. Price 2s.) continues to increase in size and scope. An interesting feature is that the entries under the various classified headings are not restricted to firms who advertise in the guide. Sections that have been especially enlarged are those relating to "Colours" and "Dyestuffs," under which many more firms are not listed. The guide should be very useful to all those who utilise chemicals or chemical plant.

Fireclay Goods.—The almost unlimited range of uses of fireclay goods is well illustrated by the productions of the Glenboig Union Fire Clay Co., Ltd., of Glasgow, a firm whose manufactures include firebricks, special bricks for various forms of metallurgical furnaces, gas retorts, sewage pipes, tiles, and many other essential industrial supplies. Chemical analyses of fireclay are liable to be misleading, but this company supplements the physical and chemical tests on its raw materials and products carried out in a well-equipped laboratory by experience gained in manufacturing fireclay goods for nearly ninety years.

Market Notes from France

Turpentine is still quoted at 500—505 fr., and although this price means a loss to most manufacturers, many are compelled to dispose of their output owing to the fairly good demand. *Clear rosins* are quoted at 82—83 fr., and it appears that the demand will continue for lower grades, as colophony is priced at only 83 fr.

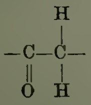
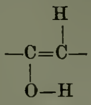
Vol. 42 NEW SERIES LONDON, AUGUST 31, 1923 No. 35

EDITORIAL

IT is nearly forty years since van Laar introduced into chemistry the conception of tautomerism, an example of which is the reversible change which takes place in certain ketonic esters where the group (*a*) easily changes into the group (*b*) and vice versa.



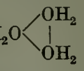
(*a*)



(*b*)

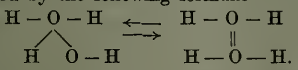
This sort of change is more intelligible since the introduction of the modern conception of molecules, consisting of various positive atomic nuclei held together by a variety of electrically negative electrons. Very slight changes of the conditions lead to a rearrangement of the electrical attractions, and even without a change in the positions of the atoms or nuclei a different method of binding them together may result, forming a distinct chemical compound. Prof. H. E. Armstrong has applied this sort of conception to water, which according to him consists of a mixture of polymers of the type

$H_2O{=}OH_2$ and



$$H_2O<\begin{matrix}OH_2\\ |\\ OH_2\end{matrix}$$

which may readily undergo change of the kind indicated by the following formulæ



With any given degree of purity, temperature and other relevant factors, an equilibrium is set up so far as these polymers are concerned, but in addition the liquid dissolves a quantity of gaseous H — O — H which he calls hydrone. The addition of hydrochloric acid to water forms a much more complicated system, but this will still contain a variety of readily interchangeable compounds which under given conditions will attain a constant relation to each other. Mendeleef, Pickering, Bousfield, Lowry and others gave consideration to this kind of problem in days gone by, but without —so far as we remember—considering in detail the various possibilities of complexity which Armstrong has indicated in a recent note contributed to the *Comptes Rendus.* It is interesting to learn, also from the *Comptes Rendus*, that M. Camille Gillet and Messrs. Kling and Lassieur have independently come to somewhat similar conclusions. That so common a substance as water and so frequent an experiment as the solution of an acid or salt in water should be so complicated is not an occasion for any surprise. Of the metals we are accustomed to, iron and steel are perhaps the most common, and how complex these are! How little is known of the structure of coal which has been chemically treated by an infinite number of methods! Mr. R. H. Atkinson writes to *Nature* to explain how to separate heavy lead from lighter lead by ordinary fractional crystallisation, and yet this process had been practised on the large scale for scores of years before its significance was observed. It is less than thirty years ago that a whole family of gases was detected in the air. Chemists need not be afraid that opportunities of research are getting limited or that they must seek for obscure essential oils extracted from a plant which flourishes where the balmy breezes blow soft o'er Ceylon's isle or for some rare mineral from Patagonia or Spitzbergen. The chemistry of air, water, iron, silica, lead, carbon and plenty of other substances is not yet exhausted. Not that the collection of rare minerals from high altitudes is to be despised; a few days spent at Bode or in the Lyngenfiord reflecting on the vanity of this world and the deceitfulness of chemists is an agreeable preliminary to an essay on a distant prospect of tautomerism. We have not heard that Armstrong has isolated the compound OH_3Cl but we have a vague and perhaps erroneous impression that $OH_2.CH_3.Cl$ and $OH(CH_3)_2Cl$ were prepared some years ago.

THE FOURTH INTERNATIONAL CHEMICAL CONFERENCE

As the official report of the Fourth International Chemical Conference held at Cambridge from June 17 to 20 under the presidency of Sir William J. Pope (*cf. Chem. and Ind.*, p. 612, 1923) has now come to hand, we publish the following extract of portions of interest to our readers :—

The Council agreed unanimously to the admission of Brazil to the Union, and it was announced that the International Research Council no longer allows international unions depending on it to admit new countries to its membership unless they belong to the International Research Council. Countries wishing to join must apply to the International Research Council, and state that they desire to adhere to the International Union of Pure and Applied Chemistry.

The Commission on Inorganic Chemical Nomenclature proposed that in future the work be confided to the editors of the *Journal* of the Chemical Society, of *Chemical Abstracts*, of the *Gazzetta Chimica Italiana*, of the *Helvetica Chimica Acta*, of the *Recueil des Travaux Chimiques des Pays-Bas* and of the *Bulletin de la Société Chimique de France*. Each country will communicate suggestions to these publications, so as to lead to the necessary discussion, and when general agreement appears to have been reached, the suggestions should be carried into effect. The Commission does not wish to decide finally what symbols should be used for Glucinium (Gl) or Beryllium (Be), and Niobium (Nb) or Columbium (Cb), and considers that a decision should be arrived at next year after the different countries have been consulted. The Commission is of the opinion that the formulæ of acids, salts and bases can be written so as to conform to the ordinary pronunciation of the respective names in each country, that is to say in Anglo-Saxon languages HCl, H_2SO_4, $BaCl_2$, etc., will be written, whilst in Latin languages ClH, SO_4H_2, SO_4Na_2, Cl_2Ba, will be written ; in the same language only one form will be adopted, *i.e.*, either $ClNa$ or $NaCl$, but not both. The word hydrate will be reserved for compounds containing H_2O, *e.g.*, Cl_2,nH_2O ; $Na_2SO_4, 10\,H_2O$. The word hydroxide will be reserved for compounds containing OH, *e.g.*, $Al(OH)_3$.

The names of the acids listed in the French Report which agree with those in the list in the Danish and American reports are to be adopted and the following acids are added :— Chromic, molybdic, tungstic, manganic and permanganic acids. Names not found in these lists will be subject to further decisions, *i.e.*, hyposulphite or hydrosulphite, pyrosulphuric acid, heptamolybdic acid, etc. Condensed acids such as pyrosulphuric and heptamolybdic acids will be considered later, but the Spanish suggestion might be adopted to designate such acids by the prefix "anhydro" accompanied by a number and followed by the specific name of the acid preceded also by the proper number, *e.g.*, chromic acid H_2CrO_4 ; potassium dianhydro-trichromate, $K_2Cr_3O_{10}$. For certain acids possessing numerous derivatives one name might be adopted, *e.g.*, heptamolybdic acid to indicate solely the hexacid $H_6Mo_7O_{24}$. Acid salts will be named in accordance with the French proposals, *e.g.*, $CaHPO_4$ calcium acid phosphate ; dihydrogen potassium phosphate KH_2PO_4. The method for suggesting the valency expressed in the French report can be adopted by all countries ; this will close the discussions on the terminations *eux, ique, a, o,* etc. The nomenclature of complex compounds requires consideration.

The Commission on the Reform of Organic Chemical Nomenclature enlarged its Executive Committee to include representatives of the same Journals as the Commission on Inorganic Nomenclature, and passed resolutions relating to the method of working. The following proposals were adopted by the Commission on the Reform of Biochemical Nomenclature :— (1) The name of a compound of known constitution should be formed according to the rules of organic chemical nomenclature. The term "glucides" is to be applied to the group including simple reducing sugars and substances which yield one or more of these sugars on hydrolysis. The term "lipoids" is suppressed, but the term "lipides" is applied to a group of substances including fats and esters possessing analogous properties, *e.g.*, lecithins, phosphatins, etc. By "protides" is meant a group of substances including natural amino acids and substances which on hydrolysis yield one or several of these acids.

It was decided by the Commission of the Bureau of Physico-Chemical Standards to enquire from Directors of Research Laboratories which physico-chemical standards were most urgently needed in order to co-ordinate the work of the Bureau. The Commission considers that the Bureau should be asked to collaborate with certain firms which have specialised in the production of pure products and to submit a scheme for carrying this out. The thanks of the Commission were conveyed to the Secretary of the Bureau, Monsieur Timmermans, for his admirable work, and the wish was expressed that he should continue to publish the critical accounts of the physico-chemical constants of organic bodies, a work of very great importance. It was also suggested that the Bureau should collaborate more closely with the Commission on Research Chemicals.

Resolutions proposed by the Commission on Tables of Constants were as follows :—The following countries have given their adhesion to the International Fund established in 1922, viz., Belgium, Denmark, Spain, United States, Great Britain, France, Italy, Norway, Netherlands, Portugal, Switzerland and Czechoslovakia, and the hope was expressed that other countries, whose adhesion was considered as certain, would actually join without delay. The establishment of the international fund, the necessity for which was recognised by the Union in 1922, is required for the very valuable International Annual Tables, which are indispensable for scientific and technical progress. It was hoped that the numerical documentation for the years 1917 to 1922 would be published as soon as possible so that the International Tables of Constants and Numerical Data could soon appear annually. In consequence it is most desirable that the subscription list under the patronage of scientific and industrial circles of participating countries will allow the Committee for the Annual Tables to realise this wish.

The modifications proposed in physico-chemical symbols are as follows :—

1. The title of the second part of the list of symbols should read "General Constants," instead of "Universal Constants."

2. In the third part, line 9, read "Molar fraction" instead of "Mole Fraction."

3. On page 505, fifth part of the list, line 2, suppress the symbol "n" in the column headed "Alternative Symbols."

4. In part 5, line 8, replace $M[\alpha]$ by $[M]$ as the symbol for "Molecular Rotatory Power."

5. Part 5, last line replace $M[\omega]$ by $[\Omega]$ as symbol of the "Molecular Magnetic Rotation."

6. On page 506, third line from bottom, delete the words "Soschmidts Number."

7. On page 509 in the paragraph headed by "Entropy," line 2, delete the words "on the ground that this symbol was used by Willard Gibbs, and also."

8. On page 511 in accordance with general usage, molecular rotatory power is defined by

$$[M] = \frac{M \times [\alpha]}{100}$$

The use of the symbol $[\omega]$ for specific magnetic rotation and $[\Omega]$ for molecular magnetic rotation, is recommended, magnetic molecular rotation being defined by the formula

$$[\Omega] = \frac{M \times [\omega]}{18}$$

These changes should be noted in the alphabetical list on page 507.

The Commission proposes to appoint a Committee to collect suggestions for additions or changes in the list of symbols. This Committee will be presided over by Prof. E. Cohen (Utrecht), and will include Professors Findlay and Marie, and an American member to be nominated by the United States National Research Council.

The Commission on Scientific and Industrial Patents concluded that, as in the Latin countries —all of which grant patents without previous examination—the unification of the legislation appears more immediately possible, these countries should begin to group themselves so as to form a single group with uniform legislation. Considering that one of the first objects to be realised should be to allow scientific men to protect their discoveries and that in addition they cannot carry out researches in secret, but must publish the results of their work as they are obtained, the Commission declares that it is inadmissible that the applicant for, or the owner of, a patent can be opposed on the ground of his own discoveries during a fixed time after their publication. The Commission also considers that scientific discoveries should be given legal protection, a question which will be studied by the Commission. To co-ordinate efforts the president of the Commission has been delegated to attend the Intellectual Co-operation Commission of the League of Nations and the International Chamber of Commerce to put forward the views of the Commission.

In consequence of the decision to increase the number of vice-presidents of the Union to six, the Council nominated Prof. Cohen (Holland) and Prof. Sakurai (Japan) as the two new vice-presidents.

The Conference decided that the Bureau of the Union should set up a Committee to get in touch with the organisations which control the exchange of students and professors between universities in the various countries, in order to co-operate and to bring about exchanges for those concerned with chemistry.

In conclusion, the Council decided that the Fifth International Conference should be held at Copenhagen.

The Report concludes as follows :—

"The foreign delegates will retain an indelible memory of their stay in the old university city, where they were able to appreciate British hospitality at its proper value. Most of them were housed in the colleges or with the professors and thus were able by this contact with English life to appreciate the preponderating part played in the activities of a nation by a university education stamped with the deep and strong traditions of many centuries. The Fourth International Conference was a real success. On leaving Cambridge the delegates paid a hearty tribute to those who had organised the meeting and particularly to Sir William Pope, the president of the British Federal Council for Pure and Applied Chemistry, to Mr. J. E. G. Harris, secretary of the local committee, and to their colleagues, who neglected nothing to provide the foreign delegations with the warmest hospitality."

ANALYTICAL CONTROL IN THE DYESTUFF INDUSTRY *

By T. CALLAN, M.Sc., Ph.D.

Analytical control in the dyestuff industry may be divided under five headings, as follows :

(*a*) Analytical control of the "raw chemical materials as brought into the factory."

(*b*) Analytical control of the "partly-finished or intermediate products," *i.e.*, material passing from process to process, as for instance, a nitro compound ultimately intended to be reduced to an amino compound, which itself might further be diazotised or coupled.

(*c*) Analytical control of "raw materials, such as engineering supplies," *e.g.*, lead, fuels, water supplies, materials for water softening, etc.

(*d*) Analytical control of "finished products."

(*e*) Analytical control of "waste products," such as flue gases, effluents, etc.

Although such a grouping is applicable to practically all chemical factories, some of the smaller ones may not control their affairs to such an extent as set forth, but in view of the fact that dyestuff factories are generally conceived on a fairly large scale, the control of each section becomes of considerable importance.

ANALYTICAL CONTROL OF RAW CHEMICAL PRODUCTS

The number of different substances used in a modern dyestuff factory as raw chemical products is extraordinarily large and covers a large range of both inorganic and organic products. In addition to the considerable number bought, a further large number is manufactured as so-called "intermediate-products." Below are appended a few of the more important substances used as raw products which have to be analysed regularly :—

Inorganic.—Iron for reduction, in the form of borings, zinc dust, sulphur, caustic soda and potash, lime, oleum, sodium bisulphate, sodium sulphite and sulphate, copper sulphate, potassium sulphate, bromine, bromide and bromates, sodium sulphide, hypochlorites, phosgene, nitric acid, nitrates, thionyl chloride, chlorsulphonic acid, lead and lead salts, tin and tin salts, bichromates, etc.

Organic.—Benzene, toluene, xylene, nitrobenzene, anilines, toluidines, xylidines, acids such as benzoic, phthalic, salicylic, chlorbenzoic, chlorbenzene, nitrochlorbenzenes, dinitrochlorbenzene, toluene sulphonchloride, phenols, cresols and their nitro and amido derivatives, etc.

Analytical control of these substances, if they are bought from outside sources, properly commences in the buying department, and thus prevents the purchase of substances of an inferior quality. It is far more important that the purchase of an impure or unsuitable product should be prevented, rather than it should be discovered when the material actually enters the factory with the subsequent arguments and claims against the seller. A very important part of the analyst's business is to draw up such specifications and this, of course, can only be done provided he knows exactly what the material is intended to be used for. Furthermore, it is important that the specification should not be unduly strict, as otherwise the price of the material might be unnecessarily raised in order that it should pass the specification. For instance, benzoic acid might be required for the manufacture of benzoyl chloride ; in this case it would be necessary to insert a very strict qualification as to moisture content, whereas if required for nitrating to nitrobenzoic acid, the moisture content would not be so important and a cheaper article might quite easily suffice.

There is little to say about inorganic substances as the methods employed for their analysis follow the lines laid down in all text books on inorganic analysis.

Text books on organic analysis, however, are comparatively rare and many students gain the impression that organic analysis consists of only determining carbon, hydrogen and nitrogen together with halogen determinations by the Carius bomb-tube method. Many methods of organic analysis really only deal with such things as titres, total organic matter, physical constants and general analytical data as given by technical organic products. Thus the analysis of an oil would mean the determination of the saponification valus, iodine value, specific gravity, etc., and very rarely indeed the actual determination of oleic, linolic and linolenic acids or the isolation and identification of the unsaponifiable matter ; similarly for the analysis of a soap or a tanning material. The organic substances used in the dyestuff industry, on the other hand, are usually "straight" chemical substances and their determination in many cases is just as straight forward as that of inorganic substances. A very considerable number of organic substances, for example, can be determined by simple volumetric processes. The methods of analyses employed can be divided into two classes, viz.:—(*a*) Physical methods. (*b*) Chemical methods involving the determination of a specific group, *e.g.*, nitro, amido, hydroxy, halogen, etc.

Physical methods.—The chief methods found of value involve determination of melting and solidifying points, specific gravity, refractive index, boiling point or, better, the distillation range and heat of reaction. The impurities to be looked for in many substances used for the manufacture of dyestuffs are in many cases isomeric or homologous with the substances itself, so that actual chemical analysis is of little value. In such cases, physical methods only can be employed; *e.g.*, in the analysis of the three nitrotoluenes—*ortho, meta and para*. The only practical way to distinguish these in the presence of each other is to determine the melting or setting point and compare with known mixtures. In many cases the determination of the setting point or crystallising point is preferable to determination of the melting point, particularly in such cases where this value is the chief criterion of purity, as, for instance, in the case of naphthalene, the naphthols, chloracetic acids, phenols and cresols, dinitrochlorbenzene, etc., as the setting point determinations can be made on large quantities of material, say a few pounds, thus eliminating sampling errors. For the determination of "setting points" the method recently introduced by Bell and Hertz of prolonging the cooling curve after the commencement of solidification on to the original cooling curve has given very good results, particularly for substances where the amount of impurity is fairly large. The determination of distillation range, *i.e.*, the temperature interval between the beginning and end of distillation, is usually more important than the actual boiling point, and many substances, such as aniline, monochlorbenzene, are required to have a very narrow distillation range. In a few cases only, however, such as benzaldehyde and carbon disulphide, is the refractive index of much importance as a means of analysis. An interesting example of the use of physical methods is the determination of small amounts of aniline, monomethyl- and monoethylanilines in dimethyl and diethyl-anilines by determining the rise in temperature when definite amounts of the dialkyamine and acetic anhydride are mixed. In the absence of the above-mentioned impurities there is a small actual fall in temperature, but when they are present the heat of acetylation is very considerable and affords quite a reliable measure of the amount present.

---

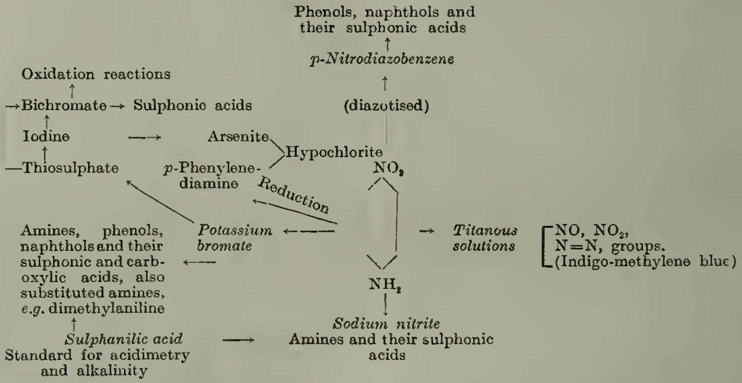
* Lecture delivered before the Evening Students' Chemical Society, College of Technology, Manchester, on February 27, 1923.

Chemical methods.—The chemical methods of analysis employed generally resolve themselves into the determination of some particular group, such as the amino, hydroxyl, sulphonic and halogen groups, and in a very large number of cases these groups can be determined quite readily by simple volumetric methods, and in comparatively few cases by gravimetric methods. With a few volumetric solutions it is possible to determine a very considerable number of organic radicles. As a very considerable number of substances used in the dyestuff industry are aromatic primary amines capable of being diazotised, they can readily be determined by titrating in acid solution with a standard solution of sodium nitrite, the end point being taken when a trace of uncombined nitrous acid is present, as shown by spotting on to starch iodide paper. This reaction is extremely sensitive, and the method is capable in experienced hands of giving very accurate results for a large number of primary amines and their sulphonic acids. Aniline, however, should not be determined by this method, as the end point is uncertain, but is best determined by titrating with standard potassium bromate solution, as will be mentioned later. It is important to determine for each substance the optimum temperature and concentration at which the titration is to be carried out—some substances, *e.g.*, peri acid (naphthylamine 1·8 disulphonic acid), titrate exceedingly slowly with nitrite unless warmed to 35° C., whilst in other cases, particularly Tobias acid (β-naphthylamine-1-sulphonic acid) and Gamma acid, it is impossible to get an accurate result if the concentration of the amino compound exceeds a certain amount, as otherwise the diazo compounds, which in these cases are insoluble substances, drag out of solution some of the undiazotised amino compound. Failure to recognise this fact has more than once led to disputes between different analysts as to the strength of samples of certain of these substances. Those of little experience who are called on to determine the strength of diazotisable amino compounds by means of standard nitrite should first determine the optimum conditions of concentration and temperature on a pure sample of the substance.

Just as a standard solution of sodium nitrite affords a ready means of titration of amino compounds, a standard solution of a diazotised amino compound affords a method of determining many phenolic compounds used as components in the manufacture of azo dyestuffs, *e.g.*, Neville and Winter's acid, H acid, chromotrope acid, etc. Although the preparation of a standard solution of a diazo compound might seem difficult at first sight, it is really quite simple:—a definite amount of a known amino compound (usually alkaline) *p*-nitraniline, *m*-xylidine, *p*-toluidine or *p*-bromoaniline is diazotised in acid solution by the addition of a slight excess of sodium nitrite and the solution made up to a definite volume with ice water. Thus 25 c.c. N/2 aniline diazotised and made up to 250 c.c. would give a N/20 solution of diazobenzene. Although such diazo solutions are usually unstable they will keep quite well if kept in ice water during the comparatively short time the titration occupies. Diazotised *p*-bromoaniline will, however, keep many hours at ordinary temperature without decomposition. Usually in such titrations the temperature is kept constant, namely, at 0° C., by addition of ice, and the chief factors to be considered are the diazo compounds to be used and the degree of alkalinity of the solutions. It is quite possible by chosing suitable diazo solutions to titrate one phenolic substance in the presence of another, as different diazo solutions differ enormously in their reactivity. Thus diazotised *m*-xylidine couples very readily and is a very unstable substance, whilst diazotised *p*-bromoaniline, which is a very stable substance, only couples very slowly.

▲

A standard solution of potassium bromate is of particular importance for determining many amines and phenols. When potassium bromate is run into an acid solution of many amines and phenols, the nascent bromine is sufficiently reactive to give immediate and quantitative bromination, and bromate solution can, therefore, be run in until the substance is quantitatively brominated and a slight excess is present as indicated by spotting on to starch-iodide paper. It is important to note that this method affords information as to the orientation of substituting groups, for the bromine always enters the ring in the *ortho* or *para* and never in the *meta* position. Standard potassium bromate affords, therefore, a rapid and accurate method of determining such substances as aniline, toluidines, sulphanilic acid, phenol, resorcinol, etc.



Phenols, naphthols and their sulphonic acids

Amines, phenols, naphthols and their sulphonic and carboxylic acids, also substituted amines, e.g. dimethylaniline
Potassium bromate
Titanous solutions
NO, NO₂, N=N, groups. (Indigo-methylene blue)
NH₂
Sodium nitrite
Sulphanilic acid
Standard for acidimetry and alkalinity
Amines and their sulphonic acids

Nitro, nitroso and azo groups are usually estimated by Knecht's method of titrating with titanous salts, either the chloride or sulphate. Many nitro compounds which reduce to diazotisable amines can be estimated by reducing with excess of zinc dust in acid solution and subsequently determining the amine so formed by titration with standard sodium nitrite. An interesting method for determining the nitroso group is Clauser's method, in which the nitroso compound dissolved in glacial acetic acid is treated with phenylhydrazine and the solution heated. A rather complicated reaction takes place with the quantitative liberation of gaseous nitrogen, which can be measured in the usual way.

Attention is drawn to the advantages which *p*-nitraniline has as an ultimate standard to which the greater number of the substances previously mentioned can be referred ; it can readily be obtained in a high degree of purity, and affords a most convenient method of standardising various volumetric solutions. The advantages of having a single ultimate standard are obvious. The diagram, which is given above, will show the various substances which can be standardised by its use.

Analytical Control of Engineering Supplies

The analytical control of such materials as lead (which is used very largely in chemical plants), fuels, water supplies and water softening plants, is of considerable importance to the dyestuffs industry. The analyst is also very often called on to advise as to the suitability or otherwise of some "anti-corrosive" metal to be used in chemical plant. This often implies prolonged experiments with the actual liquors which the plant has to handle.

Analytical Control of the Finished Chemical Products

The finished product of a dyestuff factory is, of course, chiefly colour but many colour factories produce certain intermediates in excess of their own requirements and these when sold require the same analytical control as a bought product. In addition certain substances, such as betanapthol, paranitraniline, etc., are sold directly for dyeing purposes, although themselves not dyestuffs. In the case of dyestuffs, chemical analysis is rarely used as a method of standardisation, an actual dye trial being generally preferred, the advantage of this being, of course, that not only strength, but also shade, is determined at the same time. Even for dyestuffs for which exact methods of analysis are available, *e.g.*, methylene blue, indigo, and many azo dyestuffs, chemical standardisation is rarely demanded. Certain dyestuffs, however, are sold primarily for colouring foodstuffs and these are always subjected to very strict analytical control to ensure purity and the absence of such poisonous metals as arsenic and lead. These two substances are invariably present in ordinary commercial dyestuffs, so that colours intended for foodstuffs have consequently to undergo a careful purification treatment and strict analytical control is therefore necessary at every stage.

FORTHCOMING EVENTS

Sept. 10–13. The Institute of Metals. Annual Meeting at Manchester. *Second Annual Autumn Lecture.* "The Use of Non-Ferrous Metals in Engineering," by Lieut.-Col. Sir Henry Fowler, K.B.E., at 8 p.m., Sept. 10. "The Cause of Red Stains on Sheet Brass," by E. A. Bolton. "Note on 'Brinell Hardness Numbers,'" by H. W. Brownsdon. "The Behaviour of Metals under Compressive Stresses," by H. I. Coe. "On the Measurement of the Change of Volume in Metals during Solidification," by Hikozo Endo. "The Electrochemical Character of Corrosion," by U. R. Evans. "The Constitution and Age-Hardening of the Quarternary Alloys of Aluminium, Copper, Magnesium and Magnesium Silicide," by Marie Gayler. "Investigation of the Effects of Impurities on Copper (Part I—The Effect of Oxygen on Copper)," by D. Hanson, C. Maryatt, and G. W. Ford. "Experiments with some Copper Wire; Cohesion a Function of both Temperature and Cold-work," by D. H. Ingall. "The Effect of Small Quantities of Nickel upon High-grade Bearing Metal," by A. H. Mundey and C. C. Bissett. "Stereotyping," by A. H. Mundey and J. Cartland. "Hardness Tests on Crystals of Aluminium," by H. M. O'Neill. "A Dilatometric Study of the Transformations and Thermal Treatment of Light Alloys of Aluminium," by A. M. Portevin and P. Chevenard. "Effects of Rate of Cooling on the Density and Composition of Metals and Alloys," by R. C. Reader. "Crystallisation Effect on Galvanised Iron Sheets," by E. L. Rhead and J. D. Hannah. "Equilibrium in the System Gold-Zinc (based on Investigations of Electrical Conductivity at High Temperatures)," by Prof. P. Soldau. During the meeting the new metallurgical department of Manchester University will be opened by Sir George Beilby.

Sept. 12–19. The British Association for the Advancement of Science. Ninety-first Annual Meeting, to be held at Liverpool. The President, Sir E. Rutherford, F.R.S., in his inaugural address, will deal with "The Electrical Structure of Matter." *Section A.—Mathematics and Physics.* Presidential Address by Prof. J. C. McLennan on "The Origin of Spectra." Discussion with the Chemistry and Engineering Sections on "Cohesion and Molecular Forces." "The Penetrating Radiation from the Upper Air," by Prof. R. A. Millikan; "Energy of the Circulation of the Atmosphere," by Capt. D. Brunt; "Meteorological Effects on Sea Level and Tides," by Dr. A. T. Doodson; "The Production of Triatomic Hydrogen," by G. Stead and Miss B. Trevelyan; "Matter and Radiation," by Sir Oliver Lodge; "Apocoptic Expansions," by T. Smith; "Notes on the Approximate Expansions of Empirical Results," by Prof. H. Levy and H. W. Moore; "Series of Magnetic Disturbances," by Rev. A. L. Cortie; "Some Effects of Alternating Magnetism," by W. M. Morday; "Demonstration of the Frenophone," by S. G. Brown; "The Correspondence Principle," by Prof. N. Bohr; "Remarks on Quantisisation," by Prof. P. Ehrenfest; "The Structure of Atoms and Their Magnetic Properties," by Prof. P. Langevin; "The Effect of Weak Magnetic Fields on the Polarisation of Resonance Radiation," by Prof. R. W. Wood and Dr. A. Ellet; Discussion on 'The Spectra of the Lighter Elements"; "The Magnetic Rotary Dispersion in Certain Paramagnetic Liquids," by R. W. Roberts; "The Angle of Contact: Variation with Relative Motion of Solid and Liquid," by R. Ablett.

Section B.—Chemistry. The following papers are to be read:—(1) "The Formation of Precipitates," by S. Oden; (2) "The Nature and Significance of the Resin of Hevea Rubber," by G. S. Whitby; (3) "The Physical Chemistry of Interfaces," by Prof. F. G. Donnan, F.R.S.; (4) "The Quantum Theory in Chemistry," by Prof. G. N. Lewis; (5) "The Bohr Atom and the Periodic Law," by Dr. N. V. Sidgwick, F.R.S.; (6) "On High Frequency Spectra and the Theory of Atomic Structure," by Dr. D. Coster; (7) "The Activation of Hydrogen in Organic Compounds," by Miss E. H. Usherwood; (8) "Membrane Potentials Considered as Diffusion Potentials," by Dr. E. B. R. Prideaux; (9) "Enzymes," by Dr. E. F. Armstrong, F.R.S.; (10) "The Relation of Certain Enzyme Actions to Tissue Differentiation and Tumour Growth," by Dr. K. G. Falk; (11) "Catalytic Actions in the System Copper, Copper-Oxide, Oxygen, and Gaseous Reducing Agent," by W. G. Palmer; (12) "Alumosilicates," by W. Vernadsky; (13) "The Chemistry of Hafnium," by Dr. G. Hevesy; (14) "The Utilisation of Volcanic Steam," by Senatore Prince Ginori Conti; (15) "The Biochemical Effect of Polarised Light," by Miss E. S. Semmens; (16) "Cotton Wax," by Dr. R. G. Fargher; (17) "The Absorption of Methylene Blue by Cotton," by D. A. Clibbens; (18) The Sulphonation and Nitration of Naphthalene," by Prof. H. E. Fierz.

Sept. 17. The Institution of Rubber Industry, in the Kelvin Room, Engineers' Club, Coventry Street, W., at 8 p.m. "Rubber Floors and Rubber Roadways," by E. J. Edwards.

Sept. 17–18. The Iron and Steel Institute. Autumn Meeting, to be held at Milan, in the Chamber of Commerce, commencing each day at 9.30 a.m. At the conclusion of the meeting visits have been arranged to Florence, Rome, Piombino, Leghorn, Genoa, and Turin.

CORRESPONDENCE

TUBE RAILWAY FIRE RISKS

Sir,—The communication on the above subject, published in *Chemistry and Industry* of August 24, would be amusing were it not for the fact that it levels a serious charge against the "Underground" authorities.

Your correspondent states, referring to the risk of fire in tube railway carriages, that "there is every condition for a serious accident," and in fairness to the authorities I consider this a serious misstatement of the facts.

In the early days of tube railways exhaustive tests were conducted to determine the fire-resisting qualities of the carriages, and in every case it was proved that there was no risk of serious damage by fire. Is your correspondent aware that the materials which he terms "inflammable . . . in a state of dryness calculated to spread fire rapidly" are rendered fire-resisting by chemical treatment? Details of suitable treatment are given in Thorpe's "Dictionary of Applied Chemistry."

In addition to this precaution, fire extinguishers of very effective patterns are placed in conspicuous positions in underground and tube railway carriages ready for immediate use; and the complete absence of fires such as your correspondent fears is sufficient testimony to the efficacy of these precautions.—I am, Sir, etc.,

W. J. Painter

Plaistow, E. 13
August 24, 1923

HAFNIUM OR CELTIUM?

Sir,—You have favoured my remarks with some friendly criticism in your current editorial. Perhaps I may be allowed to amplify slightly, as long correspondences are apt to get tedious.

My chief regret is in seeing the personal element brought so strongly into the sunlight. Prof. Partington and Mr. Holmyard are investigating a question which, along with others, *historians* might well tackle, and one, too, the importance of which is open to a difference of opinion, but it is admitted that different people attach varying degrees of importance and find varying interests in the same subjects: besides theirs is hardly a personal controversy, and at all times an impartial third party review is far more satisfactory and reads infinitely better. Even your own reviewer admits on p. 788 in his last paragraph, "We do not know what decision the International Committee on the Elements will announce, but we think . . .," a decision which will be decided from an International standpoint and by a body to which I take it Messrs. Urbain, Coster, and von Hevesy will acquiesce.

Referring to the announcement in the *Times*, your editorial continues, "but if the proposal . . . leads to the general enforcement of the principle that credit is to be given where credit is due . . ." By all means, but, to put the matter in a nutshell, does it improve the position one jot or tittle to emblazon oneself in diatribe after the results are published, especially as to-day it is possible to obtain access to almost any foreign or home journal with ease and then make use of one's own judgment?—I am, Sir, etc.,

A Hundred-Thousandth of the Chemical Brigade

August 27, 1923

PERSONALIA

It is announced that Prof. A. G. Green, F.R.S., has resigned his position as director of research and chief chemist to the British Dyestuffs Corporation, Ltd., owing, it is stated, "to his dissatisfaction at the lack of technical knowledge on the board of directors, and his belief that the permanent establishment of the dyestuff industry in this country is impossible under these conditions."

The British Research Association for the Woollen and Worsted Trades has awarded research fellowships for 1923-24 to Mr. R. Burgess, B.Sc., to investigate the damage caused by bacteria and fungi to woollen goods and yarns during storage, and to Mr. H. E. Farrar, B.Sc., to investigate the dyeing of wool with acid and mordant colours. Advanced scholarships have been granted to Mr. S. Menza (University of Leeds), Mr. T. N. T. Graham (Scottish Woollen Technical College, Galashiels), and Mr. P. M. Redman and Mr. W. Lee (Bradford Technical College).

Prof. E. Anderson, professor of chemistry in the University of Nebraska has accepted a similar chair in the University of Arizona.

The American Foundrymen's Association has awarded the John A. Penton Gold Medal to Enrique Touceda for his work in the development of the American malleable casting industry, and the John H. Whiting Medal to John H. Hall for his work on special manganese steels.

ACADÉMIE DES SCIENCES

During the meeting held on August 20, Monsieur Lindet communicated a note by Monsieur Piettre describing a process for transforming Cardiff coal into humus. In this process the coal is dissolved in pyridine, then oxidised and reduced, treatment similar to that employed in converting benzene into aniline. Prof. Le Chatelier transmitted a note by Monsieur A. Charrion on the absorption of sodium thiosulphate by photographic paper, showing that the best method of completely eliminating sodium thiosulphate from photographic papers and plates, is to wash with solutions of sodium or ammonium bicarbonate instead of pure water, the action taking place rapidly and completely eliminating all trace of thiosulphate.

NEWS AND NOTES

UNITED STATES

The Dye Industry

The census of dyes and other synthetic organic chemicals prepared by the United States Tariff Commission shows that the domestic production of dyes in 1922 by 87 firms was 64,632,187 lb., an increase of 66 per cent. compared with 1921. The sales for 1922 totalled 69,107,105 lb. valued at $41,463,790. The importance of the industry in 1922 is in sharp contrast with that of 1914, when only seven firms manufactured a total of 6,619,729 lb. valued at $2,470,096. The increase in production in 1922 is largely due to an increase in general business activity. In June the textile and other dye-consuming industries became more active and during the remaining months of the year the demand for dyes steadily increased. One of the conspicuous developments of the year 1922 was the increased production of vat and alizarin dyes. The total production of vat dyes (not including indigo) was 1,075,992 lb. (345,152 lb. in 1921), and that of anthraquinone dyes, including alizarin dyes and a large part of the vat dyes, was 1,234,963 lb. Many important dyes were produced for the first time on a commercial scale, comprising vat dyes, alizarin, developed cotton dyes, mordant and acid dyes. The increased production of these colours, which has resulted only after large expenditures on research and most painstaking investigations, is reflected in a reduction of the corresponding imports.

The United States produces 93·55 per cent. of its requirements in dyes. Imports in 1922 totalled 3,982,631 lb., the output was 64,632,187 lb., and the exports amounted to 6,956,593 lb., so that the consumption was 61,658,225 lb. The output of dyes in 1922 grouped by classes according to their method of application was as follows :—Acid, 9,380,014 lb.; basic, 2,937,585 lb.; direct cotton, 11,931,737 lb.; lake and spirit-soluble, 1,009,512 lb.; mordant and chrome, 3,749,701 lb.; sulphur, 16,913,767 lb.; vat (not including indigo), 1,075,992 lb.; indigo, 15,850,752 lb.; unclassified dyes, 1,283,127 lb. The total output of dyes and other finished coal-tar chemicals by 164 firms was 88,368,131 lb., compared with 51,457,565 lb. by 147 firms in 1921, which represents a 72 per cent. increase of coal-tar products; colour lakes, 10,578,664 lb., were produced by 43 firms; photographic chemicals, 345,798 lb. by 7 firms; synthetic medicinals, 2,946,347 lb.; perfumes, 793,148 lb. by 17 firms; flavours, 1,215,668 lb. by 20 firms; synthetic phenolic resins, 5,944,133 lb. by 5 firms; and synthetic tanning materials, 1,910,519 lb. by 4 firms. There was a large increase in the production of tricresyl phosphate, which is used as a substitute for camphor.

Preliminary figures of the Geological Survey indicate that the production of coal tar and by-products from the by-products coke industry during the year 1922 was the greatest in the history of the industry.

Conspicuous progress has been made within the past few years in the development and manufacture of synthetic organic chemicals not of coal-tar origin. These include many chemicals used in industrial and other processes, and the field holds high promise of further expansion. The production of synthetic organic chemicals, other than those derived from coal tar, was 79,202,155 lb., during 1922 (21,545,186 lb. in 1921).—(*Chem. & Met. Eng., July* 9, 1923.)

New Use for Dyes

In an interesting article in *Industrial and Engineering Chemistry* (August 23), Mr. P. A. Kober describes a reliable method for controlling temperatures in heating processes which consists in applying a liquid dye to the heated product, the disappearance of or change in colour indicating that the part to which the colour has been applied has received a definite amount of heat. Many dyes break down readily on heating, a large proportion of those found suitable belonging to the triphenylmethane group of colours. Amongst possible applications, the method may be used in controlling the annealing of glass or the baking of cements or other mixtures, and to indicate over-heating in parts of electrical instruments. A further development consists in using two dyes to indicate when the heat applied has passed a maximum as well as a minimum temperature limit. The following dyes, in certain proportions, act as good double indicators : Chemco Blue and Chemco Red; C.P. 196 Malachite Green; Malachite Green and Rubine Red; Erythrosin and Neptune Blue.

Casein Output in 1922

During 1922, 74 factories produced 6,907,000 lb. of casein from skimmed milk. During the first quarter of 1923, 92 factories produced 2,037,000 lb. compared with 1,166,000 lb. from 64 factories during the same quarter in 1922. It thus appears that the production, both total and per factory, has increased by nearly 50 per cent.—(*Oil, Paint and Drug Rep., Aug.* 6, 1923).

A New Source of Cantharidin

Recent investigations by officials of the United States Bureau of Chemistry have shown that the blistering principle of *Cantharis vesicatoria* can also be obtained from an American beetle of the species *Macrobasis albida*, which occurs abundantly in Texas, Kansas and the adjoining States. The Spanish beetle yields less than 1 per cent. cantharidin, and the Chinese beetle 1·2 per cent., quantities which are equalled, if not surpassed by the American beetle. It is not yet known, however, whether commercial extraction from the American species is possible.—(*Oil, Paint and Drug Rep., Aug.* 6, 1923).

FRANCE

The Wood Industry

An exhibition illustrating the various technical applications of wood will be held in Lyon from October 6 to 21, and lectures will be delivered showing recent progress in the mechanical working of wood, in the paper industry, and in the chemical industries using wood as a raw material.

Congress for the Fishing Industry

The Eighth Congress for Maritime Industries and Fishing will be held in Boulogne from September 9 to 16, when numerous biological papers will be read and attention will be devoted to the utilisation and preservation of fishery products, methods of cold-storage, the marine chemical industries (*e.g.*, marine salt, iodine, soda, etc.), the utilisation of fishery by-products (fertilisers, fish-meal, oil, glue, etc.), the hydrogenation of marine animal oil, etc.

The Output of Dyestuffs

The progress made by the French dye industry is shown by the following figures indicating the output of the factories included under the Union Syndicale des Fabricants de Matières Colorantes en France during recent years :—1916, 463,344 kg. ; 1917, 961,579 kg. ; 1918, 759,771 kg. ; 1919, 2,316,388 kg. ; 1920, 6,517,401 kg. ; 1921, 5,288,016 kg. ; 1922, 7,481,347 kg. This increase has taken place mainly in the production of the commoner dyestuffs and of a few of the more expensive types, but new dyes are regularly being manufactured and put on the market.

Petroleum

Before commencing the summer vacation the Chamber of Deputies began to discuss the Government Bill for the institution of the "Office national des pétroles," which would be entrusted with the task of encouraging petroleum exploration in France and the Colonies, supervising exploitation and the training of petroleum technologists, and assisting in the formation of a fleet of oil tankers capable of supplying France with 900,000 tons of oil annually. Funds for this would be provided by the import tax of 10 fr. per m.t. of petroleum and from the 100 million fr. accumulated by the consortium of petroleum importers. Actual stocks in France total 100,000 t. of petroleum and 206,000 t. of petrol, so that the importation in 1922 consisted of : Lubricating oil 265,650 t., residues 127,324 t., paraffin 323,145 t., petrol 869,364 t., a total of 1,600,000 t. The Minister of Commerce has allocated 500,000 fr. to assist petroleum exploration in Madagascar. Already a deposit has been discovered that covers 200 sq. kilometres in the Ranobé region, and is estimated to contain a milliard metric tons of sand saturated with oil, each ton of sand yielding roughly 1 hectolitre of crude containing 26·7 per cent. of petrol and 24 per cent. of petroleum.

SOUTH AFRICA

The Sugar Crop of 1922–23

According to the *South African Sugar Journal* (May 20, 1923), the 1922–23 season's sugar crop in South Africa was 158,221 tons, as compared with 155,194 t. for the previous season. Up to the end of February, 1923, 15,831 t. had been imported (mostly from Mozambique), as compared with 16,506 t. for the previous season. Between March 1 and April 30, a further importation was made, levelling up the figures to those of the previous season. In the 1922–23 season, 33,754 t. was exported overseas as against 34,515 t. for 1921–22. No stocks were carried over in the past season, whereas in 1921–22, 6379 t. were carried over. The net consumption is stated to be 144,376 t., an increase of 42,198 t. over the previous year. The new season promises well, and it is anticipated that there will be a record crop of from 180,000 to 200,000 t. of sugar.—(*Ind. Tr. J., July* 26, 1923.)

GERMANY

Prices of Chemicals in 1923

The prices of German chemicals increased during January to February, 1923, by 126·5 per cent. to 7535 times their pre-war figure, thus exceeding the wholesale index figure (5585) and that of the dollar exchange (6650). These increases brought them into line with the prices of raw materials, for which the index figure stood at 7971. According to the dollar exchange chemical prices stood in February at a gold level of 114.

Heating and Ventilation Congress, Berlin, 1923

In connection with the 25th meeting of the "Verband des Zentralheizungsindustrie," to be held in September, 1923, in Berlin, a congress will be held on heating and ventilation. The organisation of this congress is in the hands of Oberr-Rat v. Boehmer, Berlin—Lichterfelde—West, Hans Sachs-Str., 3, and E. Purschian, Berlin W.9, Konigin-Augusta-Str., 7.

Heating in the Glass Industry

The recent report of the "Wärmetechnischen Beratungsstelle der deutschen Glasindustrie" shows that the Institute has devoted its second year to the classification of heating methods in the glass industry. Previous observation had shown that special attention was paid to the Institute's publications which also treated of the costs of labour, methods, etc. Researches by engineers have shown that many plants are run below the maximum efficiency. The equivalent quantities of various fuels used in the production of glass are given. For example, for the production of 1 kg. of table-glass 2·00-2·15 kg. of coal, 2·90-3·15 kg. of lignite briquettes, 4·00-4·30 kg. of peat or wood, and 6·10-6·60 kg. of lignite are required.

The Coal Industry

In Germany, lignite is produced in three regions, each controlled by a syndicate, the Central German, with headquarters at Leipzig, the Rhenish (Cologne), and the Eastern Elbe (Berlin). The output from the three areas amounted in 1922 to 53·5 million tons, 34·8 mill. t., and 33·8 mill. t. respectively, showing increases of 64·16, 55·68, and 43·44 per cent. respectively over the pre-war figures. The following table shows the production of coal in the occupied areas in millions of tons and as percentages of the total output for the whole of Germany within its present boundaries.

	1922			1913	
	Million tons	Per cent.		Million tons	Per cent.
Saar	11·2	8·6	..	13·2	8·6
Rest of originally occupied area ..	6·0	4·6	..	7·0	4·5
Ruhr	92·6	71·1	..	110·4	71·6
Total, occupied areas	109·8	84·3	..	130·6	84·7
Total, German Empire	130·3	—	..	154·1	—

About one-third of the total coal output of the Ruhr is converted into coke. In 1922 78·2 per cent. of the coke made in Germany was produced in this area. The originally occupied zone is an important lignite area, producing 37,346,000 t. in 1922, or 27·3 per cent of the German total. Assuming that lignite has two-ninths of the calorific value of coal and converting the production accordingly, the output of coal in the German Empire, within its present limits, becomes 161 mill. t. for 1922, as against 174 mill. t. in 1913. The following table shows the combined production of coal and lignite in the occupied areas:—

	1922			1913	
	Million tons	Per cent.		Million tons	Per cent.
Saar	11·2	7·0	..	13·2	7·5
Rest of originally occupied area ..	14·3	8·9	..	11·5	6·6
Ruhr	92·6	57·6	..	110·4	63·4
Total	118·1	73·5	..	135·1	77·5

Thus, about three-quarters of the German fuel reserves are in the occupied areas. The coal and coke reparations deliveries, principally derived from the Ruhr district, amounted in 1920 to 15·6 mill. t. in 1921 to 18·2 mill. t., and from Jan.–Nov., 1922, to 17·0 mill. t.

The following table shows Germany's position among European coal-producing countries :—

Country	1913 Million tons		1922 Million tons
German Empire[1]	140·9	..	119·1
Saar	13·2	..	11·2
France[2]	43·8	..	31·2
Belgium	22·8	..	21·3
Poland[3]	40·5	..	36·4
Czechoslovakia	12·7	..	—
Great Britain and Ireland ..	292·0	..	255·9
Rest of Europe	44·1	..	—

[1] Present boundaries, excluding Saar region.
[2] Including Lorraine.
[3] Including Eastern Upper Silesia.

GENERAL

The Fauser Process for Fixing Nitrogen.

As the process of nitrogen fixation devised by G. Fauser has recently been applied on an industrial scale by the Società Elettrochimica Novarese at Novara (Italy), a brief description will be of interest.

Hydrogen required for the synthesis of ammonia is obtained electrolytically, a special device being used to avoid danger of explosion, (*cf.* J., 1923, 601 A.) The electrolytic cells require 6000 amps. and a potential difference of 2·4 volts, the current consumption being 6 kw.-hrs. per cb. metre of hydrogen, which is produced at the rate of 6000 cb.m. per day, and is over 99 per cent. pure. The ammonia-synthesis plant has a capacity of 1800 kg. per day and ranks in type between the Claude, Casale and Haber processes, but most resembles the Haber process. The gases are sent over the catalyst at a pressure of 300 atmospheres (200 in the Haber process), which facilitates partial liquefaction of the ammonia in the anhydrous state. Uncondensed ammonia is absorbed by water used to lubricate the compresser, thus dispensing with the need for high-pressure pumps. The dissolved ammonia is recovered by passing through a heat exchanger warmed by gas coming from the reaction chamber. In addition the condenser column is utilised for the absorption of the ammonia. Attached to the ammonia-synthesis plant is a Frank and Caro apparatus which yields 10 tons of nitric acid (36° Bé) per day. The oxidation apparatus is provided with a means for recovering the residual gases, which contain much nitrogen and a little oxygen and are mixed with a calculated volume of hydrogen and passed over platinised asbestos to remove the oxygen as water, leaving almost pure nitrogen for use in synthesising the ammonia. This method of preparing pure nitrogen without having recourse to liquefaction appears to be very economical. It is reported that the consumption of direct current per kg. of nitrogen produced as ammonia is 17 kw.-hrs., 19 kw.-hrs. being required for the production of 1 kg. of nitrogen in the form of nitric acid.

The World's Output of Salt

According to *Commerce Monthly*, the world's production of salt in 1920 was about 18,700,000 tons, compared with approximately 17,200,000 gross t. before the war. Whereas the output of the United States has increased from 4,300,000 t. in 1913 to 6,107,000 t. in 1920, that of the United Kingdom declined from 2,248,000 to 2,158,000 t. during the same period. The output for other countries was as follows, the figures for 1913 being given in parenthesis :—Russia, 539,000 (1,910,000) ; Germany, 2,887,000 (1,888,000) ; France, 1,230,000 (1,262,000) ; Japan, 580,000 (610,000) ; Austria, 79,000 (Austria-Hungary, 585,000) ; Spain, 974,000 (59,000) India produced 1,764,000 t. in 1919, compared with 1,299,000 t. in 1913.

REVIEWS

THE PHASE RULE AND ITS APPLICATIONS. *By* PROF. A. FINDLAY, M.A., Ph.D. *Fifth edition. Pp. xvi+*298. *London; Longmans, Green & Co.*, 1923. *Price* 10*s.* 6*d.*

The new edition of Prof. Findlay's instructive book contains a considerable amount of new matter. Multi-component systems have received further attention, and the section on iron-carbon alloys has been revised for the second, but not, we suspect, for the last, time. The sections on sulphur and phosphorus have been rewritten, and an interesting study has been included of the conditions of formation of calcium aluminium silicates. These additions undoubtedly increase the value of the book.

The appearance of a fifth edition of a textbook of this nature in itself renders unnecessary the praise of a reviewer, and discounts his criticisms. Yet perhaps a few general remarks may not be out of place, from one who remembers, as a student, reading the first edition with great interest and pleasure.

Professor Findlay's book is a general introduction to the study of heterogeneous chemical equilibria. The phase rule is only one of the guiding principles which can be brought to bear on such problems. It is, itself, a generalisation of commonsense principles which were applied to specific problems long before the phase rule was enunciated. For some reason, difficult to appreciate after the lapse of years, its discoverer succeeded in concealing this simply derivable rule in a forest of mathematics. Its subsequent rescue and adoption by Roozeboom had, therefore, a certain element of romance; and the romance has succeeded in clinging to this day. The phase rule is still "trotted out" as a kind of infant prodigy; we are called upon to admire the variety of its performances, and its strict adherence to the truth; and more books and lectures have been named after it than after any single important theorem in physics or chemistry.

These somewhat flippant remarks are made deliberately, since the average student, much though he may learn from Prof. Findlay's and other books on the subject, is often left a little puzzled in the end as to the real value, and the limitations, of the phase rule in the study of heterogeneous equilibrium. Indeed, in spite of its title, a large portion of Prof. Findlay's book owes little of its value to the application of the phase rule. In the interpretation of experiments on heterogeneous equilibria, the phase rule does not carry one far without the help of other considerations such as Le Chatelier's theorem, which is simply another application of the second law of thermodynamics. Clear writer though Prof. Findlay is, he is not always quite clear on this point. For example, early in the introductory chapter we find these words: "What are the *conditions* under which these two forms (of sulphur) can exist in contact with liquid either singly or together, and under what conditions can the two solid forms exist together without the presence of liquid sulphur? To these questions an answer can also be given with the help of the phase rule." Now, the phase rule allows one to deduce that it is feasible that each of the systems rhombic sulphur-liquid; monoclinic sulphur-liquid; rhombic-monoclinic; can exist in stable equilibrium at a series of temperatures and pressures; and that the system rhombic-monoclinic-liquid may exist in stable equilibrium at one pressure and temperature. The phase rule does not enable us to predict, for example, that rhombic and monoclinic sulphur can in fact exist together in stable equilibrium with the liquid phase; all it says is, that if they so exist, then it is only at one temperature and one pressure. Again, in Chapter XII., where the author summarises the application of the phase rule to systems of two components, it is stated that "The interest and importance of investigations into the conditions of equilibrium between two substances, lie in the determination, not only of the conditions for the stable existence of the participating substances, but also of whether or not chemical action takes place between these two components; and if combination occurs, in the determination of the nature of the compounds formed, and the range of their existence. In all such investigations the phase rule becomes of conspicuous value on account of the fact that its principles afford, as it were, a touchstone by which the character of the system can be determined, and that from the form of the equilibrium curves obtained, conclusions can be drawn as to the nature of the interaction between the substances." Now, is not this somewhat misleading to the student? Take the case of two components, A and B, which form a discontinuous series of mixed crystals so that all liquid mixtures of A into B have freezing points higher than A, and the freezing-point curve shows a definite discontinuity at one point (Fig. 56). What does the phase rule teach in this case as to the nature of the interaction between A and B? Surely nothing at all. It would be quite consistent with the phase rule by itself to say that such a curve should represent the normal freezing point curve of two components which form neither a compound nor mixed crystals. Other principles show that in such a case the freezing point of each component must be lowered by the addition of the other, and, therefore, that the temperature at which the two can exist in stable equilibrium with a liquid phase must be lower than the freezing points of either pure component (Fig. 67, I). None of the typical curves given in Chapter XII. can be interpreted in the light of the phase rule alone; on the other hand, they can all be interpreted with the help of other principles, the phase rule supplying a useful check on the accuracy of the interpretations.

As one further example of some ambiguity in the application of the phase rule may be chosen the much-discussed equilibrium between hydrogen and palladium (p. 141). The discussion on the interpretation of the curves obtained by Roozeboom and Hörtzema has to a large extent centred round the theories (1) that a definite compound is formed, (2) that two solid solutions are formed. Now, if the curves represent true equilibrium, the phase rule leads to only one conclusion—namely, that under the experimental conditions two solid phases are never present together. The formation of two solid phases must, therefore, be ruled out altogether. Whether the results are consistent with the formation of a compound which forms a completely homogeneous mixture with the remaining solid phase, rests on other considerations. Why, then, is "the assumption of the formation of two solid solutions more satisfactory than that of the formation of a compound" though "it does not entirely explain the facts"? The phase rule categorically denies the former, but not the latter.

In view of the importance of the application of other considerations based on the second law of thermodynamics in the interpretation and prediction of heterogeneous equilibria, it would seem advisable, even in an introductory textbook, to lay more stress on the quantitative nature of the phenomena observed. Prof. Findlay avoids this, presumably because it is liable to introduce mathematics; but is it reasonable to assume that the modern student of physical chemistry knows no mathematics? Something may be gained with little recourse to mathematics. For instance, if two components tend to form a compound—*i.e.*, if the molecular attraction between A and B is greater than that between individual A molecules, then the vapour pressures of the mixtures at constant temperature will tend to be lower than in the "ideal" state, whilst the effect of B in lowering the freezing point of A will be greater. If the two components tend to separate, the reverse relations hold. Two figures (70 and 72) given in the book afford an example of this. Toluidine forms a compound with phenol, but none with *o*-nitrophenol; consequently, we find that the influence of phenol in lowering the melting point of toluidine is greater than that of an equal molecular proportion of *o*-nitrophenol, as may be seen by superposing the curves. The intimate relation between vapour pressure and freezing curves of mixtures is very instructive, but is seldom brought out. It is a useful and simple exercise for a student to measure the effect of the addition of alcohol and of alcohol containing a little water, on the freezing point of benzene down to say 0° C., and to deduce what he can from the results as to the general behaviour of mixtures of benzene and aqueous alcohol (*a*) in the light of the phase rule, (*b*) in the light of other considerations. Such an exercise would serve to illustrate the above remarks, and has a further merit of being of some technical importance.

The views expressed above have been called forth by re-reading Prof. Findlay's book. They must not, of course, be taken as a general criticism of the book. On the contrary the book has been and will continue to be of the greatest value in the teaching of the subject. The fifth edition is even more interesting than the previous editions, and the author has evidently devoted much care in bringing it up to date.

H. T. Tizard

Mémoires et Rapports sur les Matières Grasses. Congress de la Production Coloniale de l'Exposition Coloniale de Marseille, 1922. *Vol. I. Pp.* 476. *Vol. II. Pp.* 211. *Marseille: Institut Colonial,* 1922.

The struggle for an adequate and continuous supply of raw materials is a feature of modern commerce, and the insistent demands of the rapidly multiplying population of most civilised countries have led to an increasing scarcity of many commodities, not the least important of which are oils and fats. The encroachment of the manufacturer of fatty foods upon supplies formerly available as soap fats and paint oils has not been checked nor has increased demand been overcome by extended production. The greatest consumption of oil and fat products is amongst the crowded industrial populations of the temperate zones, whilst the chief source of these materials is the sparsely populated forest regions bordering on the Equator.

Most of these tropical supplies are of purely native production, which is notoriously wasteful both of labour and material. Many efforts have been made to improve these conditions, and quite considerable sums, both of public and private moneys, have been spent for the purpose of increasing output and improving quality. It cannot be said yet that success has attended these efforts, but sufficient has been learned to indicate that such success can be attained, and that the problems which have to be faced in arriving at these ends are not incapable of solution. It is also true that even the slight progress that has been made has been hindered by lack of knowledge of work that already has been done, and much duplication of labour and vain experimenting would have been saved if some form of record, which necessarily if it were to be complete would be almost international in character, had been adopted. A number of monographs have been published in English, French and German dealing with the cultivation of the West African oil palm and the preparation of oil from its fruits, and to a lesser extent this has also been done for the coconut palm. Such publications, however, only serve to show how meagre is our information and how much yet remains to be done before we can be said to have arrived at even a reasonable approximation to an economic ideal. This absence of assembled records has been very considerably ameliorated by the publication of the above "Mémoires et Rapports," and the Colonial Institute of Marseilles is to be congratulated on the publication of two volumes which are quite unique in their character and full of just such assembled information as has been so greatly lacking before. The matter contained in these volumes was delivered to the Oils and Fats section of the Congress of Colonial Production held at Marseilles last year, and presents authoritative statements as to the present position and future prospects of the oil-seed and oil industry throughout the whole of the French Colonies.

The earlier portion of Vol. I is taken up with a statement of the French Government proposal to establish a large experimental station at M'Bambey, in Senegal, to investigate the cultivation of arachis nuts; and two similar stations, one in the Ivory Coast and the other in Dahomey, to study the cultivation of the oil palm and the manufacture of oil from its fruit. It has been proposed by the French Government to use for the establishment of these stations the profits, amounting to over 8,500,000 fr., which accrued during the war to the Oils and Fats Consortium. The plans for these stations, which are both extensive and elaborate, have been set out in considerable detail, both as to land, equipment, and personnel. The Colonial Institute of Marseilles, through the person of its secretary, Monsieur Baillaud, offers the serious criticism of these plans that they are too extensive for the purpose in view, especially at the beginning of the research, and that the elaborate nature of the station equipment, besides absorbing a large proportion of the Consortium profits, practically reduces the experimental work to a trial of mechanical appliances, forgetting the fact that most of the oil-bearing seeds must necessarily be produced by the cheap labour of natives on their own farms. It is pointed out that in the French Colonies large estate production, financed by home capital and carried out under white management, is developed to a much less extent than in British or Dutch Colonies, although even there such methods of production are only in their infancy, if exception be made of copra production in Ceylon and Malaya, and of the rapid extension of plantations for the production of the West African oil palm in Eastern Sumatra. It is suggested, and with justification, that a much better system would be to copy as far as possible the methods so satisfactorily adopted in Java for similar purposes, in which the planters are associated with the Government in supporting stations for research work carried out on a comparatively small scale, improvements being afterwards translated to the estates under the joint supervision of the station experts and the estate owners.

It is impossible to enter into a detailed criticism of the remainder of the contents of these two volumes, which consist largely of statistics of production and present-day methods of cultivating such oil-bearing fruits and seeds as the olive, linseed, coconut, arachis, sesame, castor, soya, etc. The diseases to which the plants are subject are fully detailed, as also the various forms of insect attack and the best methods of countering them. In certain cases methods of oil manufacture are also described, and even the working up of waste products is in many cases discussed. These statements are evidently made by men familiar with the conditions of the country about whose productions they write and are the more authoritative in consequence.

Not the least valuable portion of the work is the very complete bibliography of recent publications on the production of oil-bearing materials and their products. This bibliography is not confined to French Colonial products only, but its sixty pages form a complete record of the most notable publications on the world's production of these valuable articles of commerce.

The volumes under review constitute one of the most valuable additions to literature of this kind which have been made of recent years.

John Allan

Monographien aus dem Gebiete der Fett Chemie. *Vol. II.*, Glue and Gelatin. *By* Dr. R. Kissling-Bremen. *Pp.* 214. *Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H.*, 1923. *Price* 6*s*. 5*d*.

The first things that one notices about this book are the poor quality of the paper used and the apology for binding. More than half of the pages are loose, and it is difficult to read the book without losing some of them. After this, having heard so often that German writers only give references to the work of German chemists, one is curious to see whether it is so in this case. One finds that here, at any rate, chemists of other nationalities are referred to fairly.

The book contains 207 pages and an index. It deals with glue and gelatin under the following headings :—(1) Their chemistry and properties. (2) Raw materials and their preliminary treatment. (3) The preparation of glue and gelatin. (4) Applications of glue and gelatin. (5) The valuation of glue, gelatin, by products and raw materials.

Only 18 pages are devoted to the chemistry and physics of collagen, glutin, gelatin and glue. Of the remainder, 107 are devoted to the manufacture of glue and gelatin, 39 to their application, and the remainder to analytical methods. It will be seen, therefore, that the book forms a strong contrast to those of Bogue and Alexander ; in fact, it may be said that it forms an excellent supplement to them. The details of manufacture are dealt with very ably. The principles of washing are fully described, and the author emphasises their great importance. Thus, in describing the preliminary treatment of skins, he insists upon the necessity of cutting them into small pieces to ensure proper penetration of the liquors. This is generally omitted by English manufacturers on account of the extra cost with the result that clarification becomes difficult owing to residual mucins and lime. Later, in speaking of clarification, the author again emphasises the point that goods treated properly in the preliminary processes require very little clarification. If liquors are difficult to clarify, it is really an admission of faulty methods. The degreasing process is dealt with fully, and the choice of solvents discussed. Three different types of German extractors are described and clear diagrams are given.

Twenty pages are devoted to the extraction of bones and skins. The effects of temperature and pressure are discussed from a common-sense point of view. A full account of the method of working of a battery of extractors is given, again illustrated by good diagrams. Lenz is quoted as an authority for the statement that bone-glue liquors can be heated to a temperature of 130° C. without hydrolysis, though later on the author states the contrary, but regards it rather as a dilemma, for if one wants the best separation of fat one must use a high temperature and risk the danger to the glutin, whilst if a lower temperature is employed the gelatin is better, but the separation of the fat incomplete ; but this does not, of course, refer to degreased bones. Several types of evaporators, including Kestner's, are described, and ten pages are devoted to drying.

In the section devoted to the applications of glue and gelatin a large collection of formulæ, mostly patented, is given. The numerous references to patent processes is a feature of the book. But, in dealing with these, not only does the author give details but explains, in many cases, the chemistry of the principles involved. In others he condemns the chemistry as unsound, and sometimes makes sarcastic criticisms which are quite pertinent. Thus in dealing with one patent where the description is particularly obscure he interjects : "Herr! dunkel ist der Rede Sinn." The last part of the book dealing with analytical process is rather deficient in detail. It is not much more than a survey of the various processes which have been proposed and many of the more modern methods are omitted, but a good description of a German method of determining the breaking strength of glued joints is given.

The book reminds one of Davidowsky's rewritten and brought up to date. It will appeal chiefly to a different type of reader from those of Bogue and Alexander, but to him it will be more useful.

S. R. Trotman

Monographien aus dem Gebiete der Fett-Chemie. *By* Dr. K. H. Bauer. *Vol. III.* Die Oele und Fette in der Textilindustrie. *By* Prof. Herbig. *Pp.* 302. *Stuttgart : Wissenschaftliche Verlagsgesellschaft m.b.H.*, 1923. *Price* 6*s*. 5*d*.

The volume under review represents a great advance on similar books dealing with oils, fats and their products for textile purposes. Chapter A deals with fats, oils and waxes. The text gives briefly the constants for analytical purposes, and in most cases the components that have been recognised in the different oils. This is followed by methods of extraction, commercial classification, application, adulteration and examination. In the methods of extraction, the use of solvents other than carbon disulphide is not mentioned, and in future editions it would be an advantage to the textile chemist if the harmful adulterants were indicated a little more prominently. Tea-seed oil, which has been largely used in the textile industry, is not referred to, nor is any reference made to olive oil substitute which has been produced by partial hydrogenation of certain vegetable and marine oils. In the section dealing with waxes, paraffin wax is only mentioned as an adulterant in spite of the fact that it is very largely used in this branch of industry. Chapter B deals very well indeed with the analytical examination of oils and fats. Chapters C and D give a brief description of the production of textile soaps and washing agents and their laboratory examination. This chapter, although brief, contains valuable information for the textile technologist. The recipes given are probably used in Germany, but it is doubtful whether they would be accepted by the majority of users in this country. Most probably this is due to the different methods of working in the two countries.

Chapter E is divided into two parts : A dealing with oils for woollens and worsteds and the analysis of oil emulsions ; B with the preparation, properties, constitution and application of sulphated oils. Chapter F deals with the laboratory examination of sulphated oils and similar products. The book is well supplied with references to original communications or to abstracts of these, and gives a comparatively up-to-date account of most work that is of interest to the textile chemist. The book can be thoroughly recommended to the student and the textile technologist.

L. L. Lloyd

Errata.—On page 812 of the issue for August 24, col. 1, 7 lines from the bottom, read " optimal " for " optional," and on p. 818. under " Eucalyptus oil as a motor fuel," for " eucalyptus oil alone, 28 miles per gall." read " eucalyptus oil alone, 36 miles per gall."

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Aug.* 23)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Brass goods	235
Belgium	Shellac, chemical products	220
Brazil	Tyres, heavy chemicals	236
"	Drugs, chemicals	237
British India	Steel	*
British West Indies	Paint, varnish	216
Canada	Cast iron pipe	217
"	" " (tender)	11942 & 11961 /E.D./E.C.
Greece	Sugar	221
Italy	Metals and alloys, phosphorbronze	222
Netherlands	Artificial leather, leather cloth	225
Sweden	Leather	229
United States	Copper cable	233

* Director General, India Store Dept., Branch No. 10, Belvedere Road, London, S.E. 1.

TARIFF CUSTOMS EXCISE

Australia.—Imports of caustic soda from Great Britain and of calcium carbide from Jugoslavia are liable to dumping duty, whilst steel from Czechoslovakia and electric immersion heaters from Germany are exempt.

French West Indies.—The duty on heavy oils, residues of petroleum and other mineral oils has been reduced to 10 centimes per 100 kg.

Gold Coast.—Perfumed spirits will be admitted under the rating for duty at 15s. per imperial gallon.

Italy.—An export licence will be required for cinders of zinc, scrap tin and cinders of tin, and for sugar.

Norway.—A stamp tax has been levied on sugar goods.

SAFEGUARDING OF INDUSTRIES ACT, PART I

The Referee has concluded that there is no evidence that Rochelle salt has been wrongly included in the list of articles dutiable under Part 1 of the Act, and therefore decides that the complaint which has recently been heard fails.

COMPANY NEWS

B. Laporte, Ltd.

The report for the year ended June 30 shows a net profit of £20,714, as compared with £17,586 for the preceding year, £3975 being brought forward. It is proposed to write £441 off goodwill account, to transfer £2000 (against £1000) to bad debts reserve, and to pay a dividend at the rate of 11 per cent. (10 per cent.) per annum on the ordinary shares, less tax. A balance of £10,038 was brought forward, £5847, recovered in respect of E.P.D., was placed to taxes suspense account, which, after deducting payments for income tax and corporation profits tax, shows a balance of £10,547. Altogether £17,933 was spent during the year on additional plant and buildings.

United Indigo and Chemical Co., Ltd.

It is proposed to pay dividends of 5 per cent. per annum for the six months ended June 30 on the ordinary shares, less income tax (at 4s. 9d. in the pound); a further dividend of 10 per cent., less income tax (at 4s. 10½d. in the pound), on the ordinary shares, which makes 15 per cent. for the year ended June 30. A further dividend of 10 per cent., less income tax at 4s. 10½d. in the pound, is to be paid on the preference shares, making 15 per cent. for the year, the dividends being payable on September 1. On both classes of capital 12½ per cent. was paid for each of the two preceding years.

Calico Printers' Association, Ltd.

The amount standing to the credit of the profit and loss account of this company is £1,037,579, the net profit for the year ended June 30 being £800,208 and the sum of £237,371 being brought forward. It is proposed to pay a dividend of 10 per cent. per annum on the ordinary shares, with the addition of a bonus of 2½ per cent.; £150,000 has been carried to general reserve, and a similar sum to the fund for equalising dividends, whilst £100,000 has been added to the employees' benefit fund, the carry-forward being £235,432.

NEW WATER-RESISTING GLUE

The formula for casein-silicate glue developed by the Forest Products Laboratory at Madison, Wis., during the war, has recently been improved by the addition of copper salts, thereby giving better strength, water resistance and working properties. The United States Patent Office has granted a patent for this glue for dedication to the people of the United States for free use.—(*Chem. & Met. Eng., July* 16, 1923.)

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Although the demand continues on the dull side there has been a slightly better tone of late. The Home trade position shows little signs of recovery and all business transacted is very much of a hand-to-mouth order. Manufacturers have reduced their prices of Bleaching Powder by 2s. 6d. per ton, otherwise prices are steady.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d.—5s. per carboy d/d. Quiet in textile circles.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£27 per ton.
Powder	£28 per ton. (Packed in 2-cwt. bags, carriage paid buyer's station.)
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.–£5 per ton. Export demand continues good and manufacturers are in many cases fully sold for some time ahead.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d, per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Trade generally is on the quiet side, due to holidays and the Continental situation.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8—£10 per ton according to grade. Market quieter.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2s. per gall. 24° Tw.
Red Liquor	10d.—1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P Fairly regular demand.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5–£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 4d. per lb.
Crude 60's	3s. 3d.—3s. 4d. per gall. Steady demand for early delivery.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.—2s. 4¾d. per gall.
Dark	1s. 10d.—2s 0½d per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price.
Anthracene Oil—	
Strained	8¾d.—10d. per gall. Supply short. Fair enquiry.
Unstrained	8½d.–10d. per gall. Market short.

Benzole—	Fair enquiry.
Crude 65's	11¾d.—1s. 1½d. per gall.
Standard Motor	1s. 6½d. per gall.
Pure	1s. 9d.—2s. per gall. Fair demand.
Toluole—90%	1s. 8d.—1s. 9½d. per gall. Not much demand.
Pure	2s. per gall.
Xylol	2s. 3d.—3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8d.—9d. per gall. Market steady.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d.—1s. 5d. per gall. Quiet.
Solvent 90/190	1s. 4d.—1s. 7d. per gall. More enquiry.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Very little business.
Whizzed or hot pressed	£11—£12 per ton. Quiet.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton.
Pitch, medium soft	135s.—150s. per ton. No buyers at present.
Pyridine—90/140	19s.—20s. per gall. Market firm for near delivery.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 8d.-1s. 9d. per lb.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d. per lb. naked at works. Good demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 2d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Quiet.
m-Cresol 98/100%	2s 1d.—2s. 3d. per lb. Fair demand.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Fair demand.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market remains dull generally, although for one or two commodities there seems to be an increasing demand.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	2s. 11d.—3s. 2d. per lb. A fair demand exists.
Acid, Benzoic	2s. 3d. per lb. Neglected.
Acid, Boric B.P.	Cryst. £56 per ton, Powder £60 per ton.
Acid, Citric	1s. 5½d.—1s. 7d. per lb., less 5%.
Acid, Gallic	3s. per lb.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicylic	2s. 1d.—2s. 2d. per lb. Market firm with upward tendency.
Acid, Tannic	3s. per lb.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market continues weak.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very quiet.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	18s. per lb. Reduced prices have not resulted in much more business.
Benzonaphthol	4s. per lb.
Bismuth Salts	A steady market.
Borax B.P.	£31—£33 per ton, carriage paid buyer's station.
Bromides	There are still heavy stocks here to be realised, so that higher prices are not likely at present.
Calcium Lactate	2s. 6d. per lb. for best makes, Better inquiry.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	Can now be imported free from duty. Spot supplies very scarce and prices erratic from £100—£110 per ton. Lower prices for forward delivery.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	3s. 9d. per lb. With lower prices for forward delivery.

Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality and quantity.
Menthol	40s. per lb., less 2½%. Slightly firmer.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 3d. per lb. for carboys.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid: Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9s., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 9d. per lb. Lifeless.
Paraldehyde	1s. 4d. per lb. Weaker.
Phenacetin	6s. per lb. Quiet.
Phenazone	7s. per lb.
Phenolphthalein	6s. 6d. per lb. Better supply.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s. 0d.—3s. 6d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Permanganate	9½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. in bulk packages. Good steady demand.
Resorcin	5s. 6d. per lb.
Salol	2s. 8d. per lb. Very quiet. Lower in value.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 3d. per lb. Slow of sale.
Sod. Citrate, B.P.C. 1923	2s. 2d. per lb. for cwt. lots.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand. Expected to improve with continued warm weather.
Sod. Salicylate	Powder 2s. 5d.—2s. 7d. per lb., and Crystal at 2s. 6d. —2s. 9d. per lb. Shorter supply.
Sod. Sulphite, anhydrous	£27 10s.—£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25-£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. 9d. ,, ,,
Amyl Butyrate	7s. 6d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,

TRADE NOTES

Rubber Consumption in the United States

The Rubber Growers' Association has forwarded the following statistics (supplied by the Rubber Growers' Association of America) relating to the rubber industry in the United States for the second quarter of 1923:—*Consumption* of crude rubber 80,098 tons; this figure is believed to represent 90 per cent. of the total consumption. *Inventory* stocks on hand at June 30, 1923, 100,885 tons (including 93,169 tons of plantation rubber). This figure is said to represent 95 per cent. of the stocks. In addition to the above figures 27,990 tons of rubber is afloat for U.S. ports and 15,017 tons of reclaimed rubber has been produced.

Dyestuffs from the Occupied Areas

The Union Syndicale des Fabricants de Matières Colorantes en France and the Belgian Minister of Finance are putting on sale on behalf of their representative Governments a part of the stock of dyestuffs seized in May in the works of the Badische Anilin und Soda Fabrik (Ludwigshafen), of Meister, Lucius, und Bruning, of Kalle, and of Weiler Ter Meer. The stocks total 6100 metric tons and include chiefly indigo (paste, powder and reduced), alizarin, etc. After deducting the amount required for the French and Belgium consumers of dyes, who have been deprived of supplies since January by the cessation of German reparation deliveries, roughly 3000 tons of dyes will be sold for export.

French Company News

As the shares of the Société de Pechelbronn are now officially quoted, some details about this company will be of interest. Founded in 1921 with a capital of 45,000,000 francs, the company exploits a concession extending over 44,000 hectares to the north of Strasburg. Production from wells and borings amounted to 700,110 metric tons in 1922 as against 55,575 tons in 1921. The company possesses modern refineries which treated 73,860 tons of crude petroleum in 1922. Recent exploration has revealed the presence of new oil-bearing zones. The company possesses a special department which can undertake exploration in any part of the world.

British Trade Marks in Japan

H.M. Commercial Counsellor, Tokio, wishes to draw the attention of United Kingdom firms trading or contemplating trading with Japan to the fact that cases frequently occur of the infringement by Japanese firms of United Kingdom trade marks. He therefore wishes to impress on British firms the advisability of registering their trade marks in Japan, as by so doing they will not only protect their own interests, but will enable the Japanese Patent Office to have a proper record for reference purposes and to cite the marks so registered against any subsequent applications for registration of similar marks in Japan.—(*Official.*)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES London, September 7, 1923 No. 36

EDITORIAL

We have heard some of the older chemists argue that the modern chemist is too restricted in his conception of the science and that he concentrates all his attention on one small branch of it, thereby losing a sense of proportion and becoming unable to bring a sound judgment to bear on the new discoveries made even in that branch with which he is most familiar. Very likely there is a great deal of truth in the complaint, but it becomes more and more difficult to keep in touch with even the important discoveries and developments of our science. Such fundamental questions as the nature of water and the structure of benzene now require some acquaintance with electrical phenomena, the laws of electrical attraction, thermodynamics, vapour tension and solid geometry, as well as a considerable knowledge of chemistry, and how few of us have both the time and the inclination to pursue these topics to the necessary degree. One might expect that a physicist, in dealing with chemical questions, would take a very broad outlook on the subject, and we confess that we were puzzled by a statement by Sir J. J. Thomson, which seemed to be one of the texts upon which he delivered a lecture in America this spring. His statement is as follows: "The atomic theory had little effect on the progress of chemistry as long as nothing was known about the structure of the atom." We do not profess to a very exact knowledge of the subject; like an early writer we are "rather dimly impressed with some glimmering notions from old poetic associations than strongly fortified with any speculations reducible to calculation on the subject." Perhaps some of our readers who are better acquainted with the history of chemistry can tell us whether we are justly perplexed by Sir J. J. Thomson's statement or whether it is merely another proof that our mind is somewhat out of focus.

* * *

There is much in the Shipping and Engineering Exhibition at Olympia of interest to chemists, not only mechanical devices and plant required by chemical manufacturers, and new developments in the use of chemicals, but some few exhibits of which raise important questions in connexion with pure chemistry. Of these, Professor Hele-Shaw's Stream-Line Filter is the most impressive. What its commercial significance may be is difficult to forecast, but it provides a means of experimenting on the size of particles which may throw great light on theoretical conceptions of molecules. The filter appears to a casual observer to separate from a liquid all or almost all the particles which exceed a very minute size; whether this is a five-hundred-thousandth of an inch, or what the size is we do not know. We gather that dyestuffs are removed from solution or suspension and even, incredible as it may seem, that a proportion of salt may be filtered out from sea-water. One result seemed to us to be singular, that a solution of copper sulphate may be filtered so that the liquid comes out a light green and not blue colour. Now, whether copper sulphate in solution exists in the form of large aggregates of copper sulphate and water or in the form of small ions less in size than even a molecule of copper sulphate is much debated. It may be that the stream line filter will throw some light even on the problem of solution. We should dearly love to have the time and knowledge to play with one of these filters for a few months, but it will surely be difficult to obtain very exact measurements of the infinitely small channels through which the fluid escapes.

OBITUARY

DR. E. K. MUSPRATT

We regret to announce the death, on Saturday, the 1st inst., of Dr. E. K. Muspratt, Honorary President of the United Alkali Company, Ltd., and for several years Pro-Chancellor of the University of Liverpool.

Dr. Muspratt died at Seaforth House, not far from Liverpool, which was built by his father about eighty years ago, and where Dr. Muspratt lived the greater part of his life, which extended over the great span of ninety years.

Edmund Knowles Muspratt was the youngest son of James Muspratt, the founder, a hundred years ago, of the alkali industry in Lancashire. He was born in the year 1833 at Linacre, near Bootle, and sent to school at Worksop. In 1850 he was sent to Germany to study chemistry under von Liebig, at Giessen, where his two elder brothers had already studied; he became an intimate friend of the family, and when von Liebig became professor at Munich, Muspratt followed him there and studied medicine and anatomy. About the year 1856 he entered his father's business and took an important part in the management of the works. In the year 1890 the businesses of James Muspratt and Sons, of Muspratt and Huntley, Sullivan and Co., Ltd., the Globe Alkali Co., Ltd., Charles Tennant and Co., and many other firms, were amalgamated in the United Alkali Company, Ltd., of which Dr. E. K. Muspratt was a director and afterwards Honorary President. He was also for a time chairman of the British Insulated and Helsby Cables, Ltd.

Dr. E. K. Muspratt

From his youth he was keenly interested in politics, and met many interesting men, Cobden, Garibaldi and many others who took an active part in connexion with Free Trade, Home Rule and other questions. He was a thorough Radical in politics, and unsuccessfully contested the Widnes Division as a parliamentary candidate in 1885. In his delightful book, *My Life and Work*, he gives a brief account of how Dr. Ludwig Mond, Dr. Campbell Brown and he, discussed the possibilities of a society to bring scientific chemists in touch with manufacturers, and how, with Prof. Roscoe's help, the Society of Chemical Industry was formed in the year 1881. At the first meeting of the Society he read a paper on the legislation required to deal with noxious gases; a Vice-president of the Society from its inception, he became President during the year 1885—1886, succeeding Sir W. H. Perkin and preceding Mr. David Howard in that office.

He travelled a good deal in various parts of Europe and in America, always meeting interesting people, and studying the pictures and archæology of the many places he visited. He was fond of music and the theatre, and was very helpful in organising the Repertory Theatre in Liverpool about the year 1910. Although trained as a chemist and intending to take up chemistry as a profession the requirements of the great business, in which he and other members of his family were concerned, made so great an inroad on his time that he had to abandon any idea of confining his attention to the scientific side of it. Indeed, his great devotion to politics and public affairs marked him out as a man unsuited to constant attendance in a laboratory.

He took considerable interest in local politics, and was a member of the Liverpool Town Council, and the Lancashire County Council; he was chairman of the Liverpool Chamber of Commerce, and president of the Liverpool Financial Reform Association. He was energetic, public-spirited, accomplished and generous. It is not, therefore, surprising that he took an active part in founding University College, Liverpool, in 1881, and in assisting the College in the year 1903 to become the University of Liverpool.

Dr. Muspratt married in 1861 Miss Frances Baines, a daughter of a former proprietor of the *Liverpool Times*. His son, Sir Max Muspratt, Bart., is well known as chairman of the United Alkali Company, and as one who in many ways has followed his father's example in scientific, political and educational zeal.

CHELATE CO-ORDINATION

By J. D. MAIN SMITH, D.Sc.

Werner's co-ordination theory, now over thirty years old, has been relegated by most British chemists, Prof. Lowry, I think, among them, until recently to the limbo of lost causes. Now that Werner is dead there is almost a fashion for co-ordination. It is a subject for regret that he did not live to see his theory so widely accepted and abundantly confirmed in the recent electron theories of atomic structure and by the results of the new X-ray analysis.

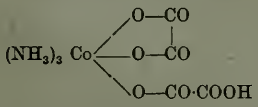
The whole of Werner's theory has a purely practical chemical foundation, and its problems have been attacked and almost invariably successfully solved by the ordinary practical methods of organic and inorganic chemistry and the application of the commonly accepted hypotheses and conclusions of general chemistry. It owes less than nothing to electrical and other physical theories of matter and energy, and little enough to physical chemistry. It is less a theory than a law, a generalisation of the facts of ascertained composition and demonstrated constitution of thousands of complex compounds.

Any extension of the co-ordination theory must be tried by the touchstone of experiment, and the evidence for it examined in the light of existing chemical experience. No attempt, however, may justifiably be made to alter the basis of the theory or to graft on to it any theory of atomic electrical polarity or electron structure of atoms. It is permissible to show its concordance or otherwise with any other theory; but Werner is dead, and his co-ordination theory should remain as he propounded it, built it, defended it, and left it—a chemical theory of the structure of *molecules*.

Prof. Lowry doubts whether ethylenediamine should be included in Prof. Morgan's classification of "chelate groups," in view of "the fact that this diamine is able to form stable co-ordination complexes only with metals of the extended transition series—*e.g.*, from V to Ga, most of which form precisely similar compounds with ammonia. In such cases the crab appears to be dead." Prof. Lowry's doubts are based on a misconception. The term "chelate" was introduced by Prof. Morgan as a convenient description of any and every group whatsoever that can contribute two associating units to a co-ordination number. It is not limited, however, merely to co-ordination complexes of addition, as it is equally applicable to carbon compounds in which the co-ordination number is equal to the valency. Like its representatives, it is all-embracing, and merely a *trivial* name summarising a number of related facts. It is independent of any theory of the mechanism as to how the union of co-ordinated atoms is attained or maintained—the crab may be alive or dead, have hooks in its jaws or muscles in its claws, and still be chelate. The only stipulation is that a chelate group must be claw-like, *i.e.*, capable of simultaneous application at two positions round an atomic sphere.

A precise definition, covering Prof. Morgan's idea, is that "a chelate group is a linked system of atoms which, in combination with another atom, completes a cyclic system." It is merely playing with words to say that a chelate group is non-centric because it is cyclic. Moreover, the terms are not mutually exclusive, for all cyclic groups have centric atoms at their reacting ends. If Prof. Lowry wishes to convey any further idea, some word other than chelate should be his vehicle.

That ethylenediamine may in some complexes contribute only one to a co-ordination number is beside the point. I am uncertain if any such cases have been proved to exist, but they are obviously theoretically possible in compounds having an odd number of groups more active in co-ordination than ethylenediamine. Oxalic acid furnishes examples of a chelate group co-ordinated by one limb and by both limbs in one and the same compound, triammino-cobaltic trioxalate, discovered by Sörensen in 1899, and demonstrated by Werner in 1912 to have the constitution :—



The purpureo-cobalt salts of dibasic acids in general furnish numerous cases of chelate groups co-ordinated by only one limb. The fact that this type of compound has been the subject of much controversy and that Werner's simple idea alone has survived is testimony of its truth.

It will be time enough to modify the term chelate group when Prof. Lowry has demonstrated that "fundamentally differing types of co-ordination" exist. All that his criticism does is to direct attention afresh to a point repeatedly insisted on by Werner—that differences in stability of co-ordination compounds are due to differences in *intensity*, not in type of co-ordination. Ethylenediamine and chelate groups in general enter into complexes of immensely greater stability than do ammonia and other unit groups, as is evident from the ease of resolution of chelate compounds into optically active forms. Co, Cr, and Rh were, in fact, all first resolved through the medium of their ethylenediamine compounds. Ammines, on the other hand, are usually racemised progressively with resolution. Thomas's neat demonstration this year of the *cis*-structure of an ammine, Erdmann's salt, was possible only after the replacement of two of the nitrite groups by the oxalato-chelate group, but even so, resolution was obtained only in solution, the solid enantiomorphs racemising in the act of crystallisation.

The experimental evidence is thus definitely against Prof. Lowry's views, and ethylenediamine must be regarded not only as a chelate group but as one of maximum activity. The co-ordination theory recognises only three classes of chelate groups according to the valency involved. These classes must be regarded only as convenient sub-divisions of a general type, differentiable merely in respect of valency. They are: bivalent chelates, such as oxalic and salicylic acids, univalent chelates, such as glycine and acetylacetone, and non-valent chelates, such as ethylenediamine and $\alpha\alpha$-dipyridyl.

I think Prof. Lowry has been led astray in proposing his two "fundamentally differing types of co-ordination" partly through zeal for the electrical theory and the difficulty of reconciling it with the facts of organic and co-ordination chemistry, and partly to oversight, attributable perhaps to a too recent conversion to the co-ordination theory. The following considerations of a steric, mechanical, physical, and chemical nature appear to have been overlooked :—

(I) The reduction in area open to attack by reagents, owing to the filling of the space round the reactive atom by the inert atoms of the chelate chain, the three hydrocarbon chains of tri-ethylene-diammines, for example, resulting in very complete enclosure, thus affording steric protection and conferring great inertness ;

(II) the mathematically slight probability of the simultaneous detachment of both reacting end-atoms of a chelate group, such as ethylenediamine, in collisions with other molecules in solutions or by thermal agitation, as compared with the probability of the detachment of a unit group, such as ammonia, under the same circumstances ;

(III) the enhancement of the tendency of any group of atoms subject to gaseous or osmotic pressure to assume the configuration having the minimum volume, a chelate group, in virtue of the spatial disposition of the valences of the successive atoms in the chain, occupying a minimum volume owing to this natural cyclic configuration ;

(IV) the lesser volatility of chelate groups as against similar unit groups—ethylenediamine, for example, as against ammonia, and organic dioximes and quinone-oximes as against nitrous acid ;

(V) the variation in the intensity of union of the reacting end-atoms of chelate groups, due to the intrinsic difference in co-ordinative properties of different atoms, and to acquired difference in the case of similar end-atoms, owing to the modifying nature of the intervening dissimilar atoms of the chain by space-filling factors and inherently different chemical properties.

In view of these considerations, it is impossible for chelate groups to be other than different, but only in degree or intensity of reactivity, not type of reactivity. It certainly is not necessary to create, as Prof. Lowry has done, a new type of co-ordination. His argument is truly as much as to say that silver florins are not coins, because some coins are gold and the commonest are copper.

The true mechanism of chemical combination may conceivably be of as many fundamentally differing types as there are compounds, but, it is logically improper, in the absence of clear evidence, to hypothecate more than one cause for very similar happenings. In chemistry, as in every other science, theories are admissible in proportion to their *necessity*, *simplicity*, and capacity to furnish a maximum of explanation with a minimum of assumption. Chemistry is ultimately founded on the hypothesis that chemical combination is of one general type, having as a criterion a common factor called valency, which is numerically measurable positively by the number of halogen atoms combined or combinable, and negatively by the number of hydrogen atoms or their equivalent combined or combinable. The co-ordination theory accepts this hypothesis broadly, but amplifies it by the further assumption that valency is the central force field of an atom in combination, which may or may not be equilibrated by enclosure by valently reacting atoms, and that such equilibration is statically attained only when the valently reacting atoms completely enclose the central force field ; in other cases equilibration is attained only by further non-valent reaction with other atoms having similarly incompletely enclosed force fields. The total number of atoms necessary for complete enclosure of an atomic central force field is termed the co-ordination number, which is, by inference, a function of the central atomic surface and the volumes of the enclosing atoms. This number is, therefore, a constant for atoms having the same atomic volume. It is convenient to refer to that portion of a central force field not enclosed by valently reacting atoms as "residual affinity" or "supplementary valency." Residual affinity is to be reckoned as accidentally but inevitably a part and parcel of ordinary or principal valency, and it is to it that all addition compounds and solution in solvents is considered due in the co-ordination theory.

Whether the foregoing central force fields have their origin in or are identical with gravitation or electricity, or both, or neither, is the province not of chemistry but of physics, and, consequently, no theory of the ultimate origin of valency or of atomic structure can be directly applied to an independent theory of pure chemistry such as co-ordination.

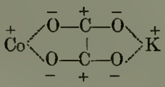
Scarcely anything in chemistry is more certain than that all co-ordination compounds are of the same type, *i.e.*, "centric," to use Prof. Lowry's unnecessary term. His "cyclic" type is already adequately provided for by existing ideas, and, as a fundamentally different type of co-ordination, is justified neither by experimental facts nor theoretical considerations. Not thus lightly can the accumulated evidence of the seventy-two years since Genth discovered purpureo-cobalt chloride and the immense and fruitful labours of Werner for over thirty years be set aside.

It may be Prof. Lowry's opinion that " the size of a ring is an important factor in determining the stability of the co-ordinated complex, but it is mainly a negative factor, since ring-formation does not decisively promote co-ordination." This statement, however, does not relate to matters of opinion but to matters of fact, and in reality the facts are otherwise than stated. It is not always possible readily to obtain decisive experimental evidence for or against any isolated point in chemistry, but in this case the evidence is at hand in one of Werner's classical examples, cited unluckily by Prof. Lowry—the ferrous *aa*-dipyridyl complex. The iron atom, though undoubtedly one of the transition elements and, therefore, of Prof. Lowry's *centric* type, is almost devoid of his centric co-ordination properties, the difficulty-obtainable ammines being instantly decomposed by water. Nevertheless, ferrous salts readily form stable compounds with *aa*-dipyridyl, which were resolved into optically-active forms, thus proving their octohedral structure and constitution as tri-*cyclic* systems with a common *spiro*-iron atom. Ferrous salts form similar cyclic compounds with ortho-phenanthroline, and the cyclic ferric double oxalates are well known. No clearer disproof could be obtained of the statement that " ring formation does not decisively promote co-ordination."

Prof. Lowry's general conclusion that " the maximum of stability should be reached in a six-atom ring containing three pairs of conjugated atoms " is also not borne out by the facts. No compound of iron is known, containing a six-atom ring, of stability at all comparable with the *aa*-dipyridyl and ortho-phenanthroline complexes, neither of which contain the metal in a six-membered or conjugated ring. The stability of these complexes is, however, stated to be due to concordant conjugation in the rest of the molecule—*i.e.*, the pyridine rings. Nevertheless, *aa*-diquinolyl and *aa*-pyridylquinoline, with yet more extensive concordant conjugation, form no compounds with iron, despite a precise resemblance to *aa*-dipyridyl in their theoretical chelate groups. The fact that no compounds, stable or unstable, are formed is proof positive that conjugation, external to a chelate group, is not even a minor factor in co-ordination.

It was early very obvious in the electrical polarity theory of atomic chains, that the existence of rings with an odd number and chelate groups with an even number of chain atoms was inexplicable by the simple form of the theory. A " difficulty dodge " was clearly necessary, of the type of " heads I win, tails you lose," so that the theory could be applied to both odd and even cases, for between odd and even as between heads and tails only one choice can be right. This was found in a verbal spell for enchanting critics, the particular " abracadabra " used being " crossed polarity." It is remarkable that, so far, polarities have been " crossed " only positively, but, as new difficulties arise, it can be prophesied with confidence that " negative crossed polarity " will become a vital necessity.

However, in case the crossed polarity medicine be ineffective, Prof. Lowry proposes a further cure for the odd-ring disease, which is even more drastic. This consists in co-ordinating alkali-metals with the other atoms external to chelate groups, potassium, for example in potassium cobaltioxalate, entering into an eight-membered bridged ring, thus :—



As a minor point, it must be remarked that this formulation does not show the true valency of the atoms, carbon, for example, is shown as tervalent instead of quadrivalent, oxygen as univalent instead of bivalent, and potassium and cobalt as non-valent instead of univalent and tervalent respectively, and the dotted bonds have not the meaning usual in co-ordination formulæ. Such bonds cannot mean half a valence, for even in the electrical theory, a valence is a unit, an electron displaced, and therefore indivisible. The co-ordination dotted bond does not affect the valency, but is merely a qualitative indication that part of the *force* due to valency is binding non-valent atoms or groups. The important point, however, is the co-ordination of an alkali metal, other than lithium, for which there is no experimental justification. The same type of formulation has previously been used by Prof. Lowry for the cobaltinitrites. In neither case does he adduce any evidence, for in fact none exists. Where such compounds are soluble, they are as completely ionised, so far as the alkali-metal is concerned, as ordinary common salt of the same atomic concentration, and the alkali-metal may be replaced in the ordinary ionic double-decompositions by other metals or basic groups, and the latter may be totally devoid of co-ordinative properties, without any loss of stability in the resulting compounds. The ammonium radicle is devoid of co-ordinative properties, yet ammonium cobaltioxalate, ferrioxalate, diamminocobaltinitrite, and cobaltinitrite are known to be stable. The hexammino-cobaltic complex (luteo-cobalt) is also, on any view of its constitution, devoid of co-ordinative properties as a whole, yet luteo-cobalt cobaltioxalate, ferrioxalate, diamminocobaltinitrite and cobaltinitrite, are extremely stable and, moreover, insoluble bodies. The last two were discovered and their stability demonstrated by Gibbs over fifty years ago. As these compounds cannot be co-ordinated in Prof. Lowry's way and yet are all very stable, his argument in favour of co-ordinated alkali-metals falls to the ground. In fact the only valent elements that appear to be devoid of co-ordination properties are potassium, rubidium, caesium, and univalent thallium, the existence of their numerous perhalides notwithstanding; the latter are practically certainly due to co-ordinated positive halogen, as is evident from the existence of similar compounds of all strong bases, such as the metal-ammines, the ammoniums and the higher alkaloids.* The lack of co-ordination in the alkali-metals has been further illustrated by Prof. Morgan and myself in the preparation of the luteo-cobalt salt of nitroso-β-naphthol, one of the most powerful chelate groups known to chemistry, this salt having the same general properties and strange green colour as the corresponding alkali-metal salts. It may be definitely stated, in view of ascertained experimental facts, that any theory of chemistry which requires more than the very feeblest co-ordinative properties in the alkali-metals, other than lithium, is built on sand and can command no credence.

Prof. Lowry's division of co-ordination into two types is, however, not justified on the grounds he cites, for the metals of the extended transition-series occasionally have no "centric" properties, and other metals often have "centric" properties as highly developed as the metals of the extended transition-series. That iron, a typical transition metal, definitely requires a chelate group for stability, has been clearly shown above. On the other hand, glucinum, boron, aluminium, silicon, nitrogen, oxygen, and fluorine, just to mention a few elements not in the transition series, do not need chelate groups to stabilise their co-ordination compounds. Sodium glucinifluoride, borofluoric acid and the borofluorides, amminoborontrimethyl, amminoboron fluoride, sodium aluminifluoride (cryolite), silicofluoric acid and the silicofluorides, all co-ordinated oxy-acids, ammonium salts, alkyl- and aryl- ammonium salts, and the many thousands of ammines of metals, are frequently extremely stable co-ordination compounds, which do not contain any chelate ("cyclic") groups. It thus occurs that nitrogen, oxygen, and fluorine, not being transition elements, must be classed as possessing only "cyclic" co-ordination. Yet they are Prof. Lowry's criterion of "centric" co-ordination. The perfect "reductio ad absurdum"! The futility of this classification is evident, when "cyclic" and "centric" types of co-ordination can be at once different and identical.

THE PRACTICE AND CONTROL OF BENZOL RECOVERY FROM GAS

THE USE OF SOLID ABSORBENTS

By **REX FURNESS**

The general acceptance of benzol as a motor fuel, either alone or in admixture with petrol, alcohol, etc., warrants the statement that the supply of benzol will not exceed the demand in this country, as the consumption of internal-combustion engine fuel runs into hundreds of millions of gallons per annum. Therefore, whatever developments may occur in the adoption of low-temperature carbonisation of coal—a process which yields a relatively large amount of light oils—it is safe to say that producers of metallurgical coke in recovery ovens will continue to strip their gas of benzol. Present-day coke is of a small or medium celled structure, hard, dense, compact and porous, and is well graphitised, so that, although it may be surpassed in combustibility, it is unlikely that a blast furnace carbonaceous material of equal or superior qualities will appear in industry in the near future. Benzol recovery from coke-oven gas is a problem, then, of present and future importance, and the newer methods of absorbing the hydrocarbon from the gas stream merit consideration.

At the present time, benzol is universally recovered by absorption in a washing oil, from which it is subsequently removed by distillation. The employment of a dry absorbent, active charcoal, silica gel, base exchange silicates, etc., offers so many advantages that its adoption should be carefully considered in all cases of plant extension. Capital sunk in the expensive stripping and recovery apparatus already in existence cannot be sacrificed light-heartedly; but here again it is a matter demanding bold examination whether the savings that can be attained by operating dry absorption plant, together with the greater yield of benzol won from the gas, are not sufficiently large to bear not only their own interest and depreciation charges, but those thrown upon the dry absorption process by the scrapping of existing plant well before its time.

ABSORPTION IN OIL

It is unnecessary to describe present-day plant in any detail, for in effect it consists merely of an oil scrubber packed uniformly with suitable material, allowing intimate contact between gas and washing oil, which pass in counter current. Preheaters for the oil containing benzol and stills for the removal of the latter and regeneration of the former vary in design and efficiency, but present problems outside the scope of this article. It is important to note, however, that the maintenance of benzol recovery at 90 per cent. efficiency demands a care and attention upon the part of operator and manager which admits of no relaxation of effort. Many factors affect the extent of benzol solution in the washing oil, namely, a sufficiency of scrubber space—together with a sufficiently prolonged time of contact between oil and gas — quality and quantity of absorbing oil, temperatures of oil and gas, state of saturation of washing oil and the amount of benzol in the gas.

Assuming that attention is paid to the mechanical details of the process of benzene absorption in oil, the most important single factor in ensuring a good stripping is perhaps the nature of the oil used. Many varieties find successful application, including coal-tar oils, blast-furnace tar oils, petroleum distillates, gas oils, and so forth. In general, however, the oil should have as low a molecular weight as is consistent with a sufficiently high boiling point, to prevent any carry-forward past the scrubbers, or contamination of the benzol in the subsequent distillation. The higher the molecular weight of the absorbing oil, *ceteris paribus*, the lower is its capacity for retaining benzol, assuming Raoult's law to hold exactly.

In this connexion reference must be made to an important paper by Wilson and Wild (*J. Ind. Eng. Chem.*, Aug., 1923, p. 801), in which the vapour pressures of benzene and other hydrocarbons in many oils are studied. Briefly, it may be said that the several types of mineral oils employed in benzol stripping are of approximately equal value, the differences in molecular weight for a given viscosity being almost exactly compensated by the divergencies from Raoult's law.

It is important, however, that the circulating oil, whatever its nature, be kept clean and finely divided solid impurities removed. It is probable that the molecular weight of the stripping oil does not sensibly increase during use by reason of polymerisation, as has been assumed as an explanation of decreasing efficiencies of benzol recovery as the stripping oil becomes older.

The temperature of absorption should be maintained as low as possible, for greater efficiencies result at low temperatures. Here, again, reference only must be given to a somewhat overlooked paper due to Cantelo (*Canadian Chem. Met.*, 1922, pp. 177 and 196) which, although relating primarily to the recovery of gasoline from natural gas, contains much of value to the by-product coke-oven manager. In this paper is given a method for calculating the amount of oil required at any temperature, to remove completely gasoline (or, in this case, benzol) from gas. Theoretically, of course, it should be possible to remove benzol completely from coal or coke-oven gas at any temperature by scrubbing with such an amount of oil as to bring the vapour pressure of the solution at the chosen temperature equal to the partial pressure of benzol vapour in the gas. The paper of Cantelo, read in conjunction with the later work of Wilson and Wild upon the deviations of benzol-oil solutions from Raoult's law, provides much valuable information regarding the practice of benzol stripping.

A factor which will demand consideration in the ensuing comparison between oil washing and absorption in a porous solid is the capacity of the scrubbers. A definite figure cannot be given, for the amount of scrubber capacity depends upon the amount of benzol in the gas, and therefore upon the type of coal carbonised; the temperature of scrubbing, the velocity of gas passage, and the efficiency of recovery demanded or the state of saturation of the washing oil attained. On an average, however, a figure can be taken of from 12 to 18 cb. ft. of scrubber capacity per ton of coal distilled per day, and it can be assumed that 10,000 cb. ft. of gas is produced per ton of coal treated. Again, figuring three gallons of benzol recovered per ton of coal, three per cent. oil-benzol solution, and a twenty-four hour cycle of washing oil, the amount of oil required in the stripping plant must be placed at 100 gallons per ton of coal treated per day. These figures will be used in subsequent discussions and comparisons.

BENZOL ABSORPTION IN CHARCOAL, SILICA GEL, ETC.

The development of decolorising and gas-absorption carbons or charcoals during the last decade, particularly during the later years of the world war, has been paralleled only by the development of highly absorptive inorganic "gels," such as silica gel, the base-exchanging silicates, and other compounds such as ferric hydroxide gel. The high efficiency naturally demanded when active charcoal had to be used as a protection against toxic gases in the field has been equalled and even surpassed by that of silica gel and other inorganic absorbents, so that these compounds present to-day a valuable material for peace-time industry. In particular, benzol can be recovered very successfully from coke-oven gas by absorption in such a compound.

It is unnecessary to indicate the methods by which active vegetable charcoals are manufactured—and the processes claimed are legion—but it will suffice to say that the original carbonaceous matter is destructively distilled, in the presence or absence of addition agents such as zinc chloride, calcium chloride, or phosphoric acid, and the original carbon complex is subsequently activated by a mild oxidation by means of steam, carbon dioxide, oxygen-nitrogen mixtures, etc. Prices ruling for highly absorptive qualities are, however, high, so that products made by relatively simple processes from sodium silicate are likely to outbid the charcoals in popularity. Silica gel, for instance, is easily made by acidifying sodium silicate solution at a definite temperature and concentration, washing out the sodium chloride formed and drying the gel at a relatively low temperature to a hard, glassy mass. This hard " gel " is highly porous by reason of innumerable minute capillaries, probably measuring in diameter not more than the equivalent of several molecular diameters. Base exchanging silicates of high absorptive value are likewise readily prepared by reaction between specific concentrations of solutions of sodium silicate and sodium aluminate. These highly efficient substances, in common with silica gel, are protected by patent rights, of course. In view of the fact that the inorganic absorbents are much cheaper, equally efficient at least, and possess a much greater density than the active charcoals, so that a much greater " space-time " absorption can be effected, or in other words, for a given duty, a smaller apparatus charged with silica gel will suffice, charcoal will be left out of discussion, since, too, the phenomena of absorption are identical in all cases from a practical point of view.

ABSORPTION APPARATUS

A good absorbent gel will hold about 25 per cent. of its own weight of coke oven benzol at 25° C., and will render up this amount on the passage of slightly superheated steam at, say, 250° C., or lower. Moreover, the gel will abstract the benzol from a relatively dilute air-benzol or gas-benzol mixture, although the " break point " and final saturation value depend, *inter alia*, upon the partial pressure of benzol in the gas. (The " break point " has been defined as that point at which the absorbent ceases to remove *all* the benzol from the gas.)

The " break point " varies, of course, with the nature of the absorbent, concentration of benzol in the gas, and temperature, but under normal operating conditions a substantial percentage of the total weight of benzol absorbed at saturation of gel is completely removed from the gas by the latter. In other words, until a certain concentration of the benzol-absorbent complex is reached, the hydrocarbons are completely stripped from the gas. In practice, therefore, three absorption units in the form and arrangement of gas purifier boxes—the ordinary iron-oxide box purifiers of the gas works—may be charged with a suitable absorbent, say, silica gel or base exchange silicates ranging in size from 8—14 mesh. Gas, freed from naphthalene, tar suspensions and, if economically possible, sulphur, is passed through two boxes in series. The benzol is removed for a considerable time by the first box, but towards the end of, say, an eight-hour cycle, benzol commences to come through box No. 1, but is easily retained by the fresh gel in box No. 2. A change over is effected after an eight-hour run, box No. 2 becoming the first box to receive the gas stream, whilst box No. 3 acts as the safety box. In the meantime box No. 1 is undergoing a steaming treatment for the recovery of the benzol, and as this process can be carried through much more quickly than the absorption, the box can be standing cooling for several hours after steaming before it is required to take its place in the absorption cycle once more. In any case, cooling tubes are fitted within the boxes, so that the heat of absorption may be prevented from raising the temperature of the gel during benzol stripping, and a stream of water is circulated through these water tubes in case the box is required at the earliest possible moment after removal of its contained benzol.

A general filter with a final section containing gel should be placed in advance of the absorption boxes. Deterioration of the absorbing gel by the deposition of tarry impurities can be almost indefinitely postponed, but although it is desirable to remove hydrogen sulphide if this is part of normal practice, it is difficult to see that this gas can interfere greatly with benzol absorption. In the absence of air, charcoal, silica gel, etc., do not effect the catalytic decomposition of hydrogen sulphide, and deposition of free sulphur upon the absorbent will not occur. In any case, it is interesting to note that the Bayer Co. claim a patent for an absorbent of greatly enhanced value, obtained by the intentional pre-deposition of sulphur up to 50 per cent. in amount.

ADVANTAGES OF SOLID ABSORBENTS

The practice of benzol stripping is simplified by the use of solid absorption agents. Little attention is demanded, constant supervision and testing are dispensed with, large volumes of circulating oil are not required, and the general operating and maintenance costs are less than in the case of absorption in a washing oil. The size of plant required is considerably reduced. Assuming, for instance, that the absorbent in box No. 1 has retained only 16 per cent. of its weight when it comes off in its turn for steaming and assuming that 100 tons of coal are carbonised per day, yielding 2520 lb. of benzol—approximately three gallons per ton, as assumed in the case of oil scrubbing—it is clear that each of the three absorption boxes must contain 5040 lb. of absorbent, say, silica gel. The total cubic capacity of the three boxes would therefore amount to 345 cb. ft., assuming that silica gel weighs 44 lb. per cb. ft. and allowing nothing for packing, spacing, hurdles, steam and cooling pipes and free space at top of box, etc. Nevertheless, the wide difference between this figure and that for the capacity of oil scrubbers—1200 to 1800 cb. ft. per 100 tons of coal treated per day—is noteworthy.

The above size of plant is quite an outside and entirely safe—perhaps excessively safe—estimate, for gas would pass through this plant at the rate of only about 2 cb. ft. per cb. ft. of gel (over all), or in the cycle suggested about 6 cb. ft. per cb. ft. of gel per minute. Now water has been successfully removed from air passing over gel at the rate of about 30 cb. ft. per minute per cb. ft. of gel, and gasoline, occurring in about the same concentration in natural gas as does benzol in coke-oven gas, has been absorbed in charcoal, the "wet" gas flowing over and through the latter at a rate of 10 cb. ft. per minute per cb. ft. of charcoal. It must be remembered that silica gel, base exchange silicates, etc., are available with an absorptive capacity at least equal to that of activated charcoal. (For a description of the process of gasoline recovery from natural gas by means of activated charcoal, see Burrell, Oberfell and Voress, *Chem & Met. Eng.*, 1921, Jan. 26, p. 156.)

The initial outlay for plant construction is much less than in the case of oil-scrubbing equipment, for from one-fourth to one-fifth of the absorption space is required, and that of very plain construction—viz., of the purifier box type, as contrasted with packed towers or complex mechanical devices for insuring intimate contact between gas and washing oil. In the 100 ton per day plant assumed in the foregoing, about 7 tons of silica gel or an equivalent absorbent would be required, and little allowance made for renewal or replacement. With oil scrubbing, 10,000 gallons of a good washing oil would be required, with constant renewal to a greater or less degree. It is probable that Engelhardt's estimate that the maintenance charges in respect of charcoal absorption of benzene from coal gas amount to one-tenth those for oil scrubbing can be safely applied to inorganic absorption. Charcoal is more costly, is more easily disintegrated in use, and it cannot be freed from adventitious impurities so easily as an inorganic gel. Finally, power charges are likely to be much less than in the case of benzol recovery in oil scrubbers, for no circulation of absorbing material obtains.

The outstanding factor in the whole comparison has already been indicated—namely, the recovery of almost the whole of the benzol from the gas stream with comparatively little attention. The apparatus is essentially "fool and low yield" proof, and returns higher benzol figures per ton of coal carbonised than does oil absorption—at any rate in general operation. In town's gas manufacture the question is not so serious—even if benzol stripping were generally in evidence—for any benzol left in the gas is paid for by the consumer, often at a higher proportionate rate than is obtained by the producing company for the extracted benzol. In coke-oven practice, however, the conditions are, in most cases, different, and it is advantageous to obtain as great a benzol recovery as is possible. Dry absorbents should therefore receive a very careful consideration, and small scale plant trials should be carried out to supplement and define the specific conditions and the estimates of gel requirements made in the foregoing account.

SOLID ABSORBENTS IN PRACTICE

It has been shown that there is no reason to fear deterioration of the absorptive qualities of silica gel if tarry matters or impurities that "smear" the active absorptive surface be excluded from the gases under treatment. Repeated absorption and recovery of the absorbed material by means of steaming the gel have no apparent ill effect upon the latter.

Charcoal has been used in the recovery of gasoline from natural gas, as noted above. The authors of the paper referred to state that installation charges upon the process are small, running expenses are light, and a higher yield of a better gasoline is obtained in comparison with that recovered by absorption in oil. Thus, the charcoal plant operating on the same gas as an oil absorption system gave a yield of 203 gallons of better gasoline per million cb. ft. of gas treated, compared with only 125 gallons for the oil system.

Englehardt reports large-scale experiments which he carried out in the Cologne gas works: 64,000 cb. ft. per day of ordinary coal gas were stripped of benzol by passage through active charcoal, contained in two boxes in series. The rate of gas passage was apparently relatively small, for the capacity of the absorption boxes was about 30 cb. ft. Each box yielded about 80 lb. of benzol on steaming, but if both were used in series as much as 112 lb. could be recovered from a box. The gravity of the benzol was 0·885, as contrasted with 0·90—0·93 for benzol obtained by oil scrubbing in comparative trials. The former benzol, too, gave only 2 per cent. distilling over 145° C., whilst the latter yielded 29 per cent. above 180° C.

Silica gel has been used for drying air, and very successful results are shown in large-scale units. The process is claimed to be cheap enough to be used to dry the air supplied to blast furnaces. Many other applications of the inorganic gels as solid absorbents are contemplated—concentration of sulphur dioxide from dilute mixtures in air, solvent recovery, absorbing lead chamber exit gases in the manufacture of sulphuric acid, etc.—but reference only must suffice here.

CONTROL OF BENZOL RECOVERY

The solid absorbents can be effectively used in the control testing of an oil absorption plant, and experience in the laboratory may well be the basis of subsequent large-scale developments. The simplicity of the test in comparison with the oil washing methods almost universally practised is at once apparent, and the efficiency is convincingly demonstrated.

Many types of apparatus have been suggested from time to time for using activated charcoal as absorbent for the benzol, but the concentric tube system is simple and effective. The absorbent is contained in the inner tube, and the gas is passed at a rate of about 10 cb. ft. per hour over approximately 500 g. of charcoal or gel. Superheated steam is then admitted round the tube, passing thence through the absorbent and carrying away the benzol to a condenser. The calculations required are obvious. The absorbent is allowed to cool and is capable of repeated use. A more accurate method, involving slightly more attention, is described by Davis (*J. Ind. Eng. Chem.*, 1923, July, p. 689) as follows:—Two tubes, 12 in. by 1·5 in., are charged with 300 c.c. of charcoal each and fitted together in a simple manner, suitable gas connexions, etc., being also fitted conveniently. Gas is passed at about 10—15 cb. ft. per hour until a quantity of benzol assumed to be roughly 40 c.c. has been absorbed. (This is known from the known approximate benzol content of the gas.) The charcoal is now placed in a flask, covered with cresol and heated to 180° C. The distillate is washed with caustic soda solution and its volume read. A similar procedure is carried through upon the charcoal in the second absorption tube. The use of this type of test simplifies the determination of benzol in gas, but its chief value is in its influence upon the mind of the operator. The simplicity, convenience and efficiency of solid absorbents is convincingly demonstrated, and the way is paved for an estimated cost survey in the particular circumstances obtaining and for experimental large-scale plant installation.

RUSSIAN METALLURGY IN 1923

In March, 1923, 28 blast furnaces were alight in Russia compared with 212 in 1914, and 37 open-hearth furnaces and 116 rolling mills were in operation compared with 243 and 178, respectively, in 1914. These figures, however, represent considerable improvements on those recorded in 1922 and previous years. The production comprised 141,400 long tons of pig iron, 228,560 t. of open-hearth steel, and 176,850 t. of rolled material, compared with the respective production of 4,151,600 t., 4,182,300 t., and 3,454,800 t. in 1913. The production of iron and steel shows an important decline compared with the figures for the same period in 1921–22. There was a large increase in the output of ore, and stocks also increased, with the exception of those of pyrites, which were not mined during the previous half-year.—(*U.S. Comm. Rep., Aug.* 6, 1923.)

"Experiments with some Copper Wire; Cohesion a Function of both Temperature and Cold-work," by D. H. Ingall. "The Effect of Small Quantities of Nickel upon High-grade Bearing Metal," by A. H. Mundey and C. C. Bissett. "Stereotyping," by A. H. Mundey and J. Cartland. "Hardness Tests on Crystals of Aluminium," by H. M. O'Neill. "A Dilatometric Study of the Transformations and Thermal Treatment of Light Alloys of Aluminium," by A. M. Portevin and P. Chevenard. "Effects of Rate of Cooling on the Density and Composition of Metals and Alloys," by R. C. Reader. "Crystallisation Effect on Galvanised Iron Sheets," by E. L. Rhead and J. D. Hannah. "Equilibrium in the System Gold-Zinc (based on Investigations of Electrical Conductivity at High Temperatures)," by Prof. P. Soldau. During the meeting the new metallurgical department of Manchester University will be opened by Sir George Beilby.

Sept. 12–19. The British Association for the Advancement of Science. Ninety-first Annual Meeting, to be held at Liverpool. The President, Sir E. Rutherford, F.R.S., in his inaugural address, will deal with "The Electrical Structure of Matter." *Section A.—Mathematics and Physics.* Presidential Address by Prof. J. C. McLennan on "The Origin of Spectra." Discussion with the Chemistry and Engineering Sections on "Cohesion and Molecular Forces." "The Penetrating Radiation from the Upper Air," by Prof. R. A. Millikan; "Energy of the Circulation of the Atmosphere," by Capt. D. Brunt; "Meteorological Effects on Sea Level and Tides," by Dr. A. T. Doodson; "The Production of Triatomic Hydrogen," by G. Stead and Miss B. Trevelyan; "Matter and Radiation," by Sir Oliver Lodge; "Apocoptic Expansions," by T. Smith; "Notes on the Approximate Expansions of Empirical

Results," by Prof. H. Levy and H. W. Moore; "Series of Magnetic Disturbances," by Rev. A. L. Cortie; "Some Effects of Alternating Magnetism," by W. M. Morday; "Demonstration of the Frenophone," by S. G. Brown; "The Correspondence Principle," by Prof. N. Bohr; "Remarks on Quantisisation," by Prof. P. Ehrenfest; "The Structure of Atoms and Their Magnetic Properties," by Prof. P. Langevin; "The Effect of Weak Magnetic Fields on the Polarisation of Resonance Radiation," by Prof. R. W. Wood and Dr. A. Ellet; Discussion on 'The Spectra of the Lighter Elements"; "The Magnetic Rotary Dispersion in Certain Paramagnetic Liquids," by R. W. Roberts; "The Angle of Contact: Variation with Relative Motion of Solid and Liquid," by R. Ablett.

Section B.—Chemistry. The following papers are to be read:—(1) "The Formation of Precipitates," by S. Oden; (2) "The Nature and Significance of the Resin of Hevea Rubber," by G. S. Whitby; (3) "The Physical Chemistry of Interfaces," by Prof. F. G. Donnan, F.R.S.; (4) "The Quantum Theory in Chemistry," by Prof. G. N. Lewis; (5) "The Bohr Atom and the Periodic Law," by Dr. N. V. Sidgwick, F.R.S.; (6) "On High Frequency Spectra and the Theory of Atomic Structure," by Dr. D. Coster; (7) "The Activation of Hydrogen in Organic Compounds," by Miss E. H. Usherwood; (8) "Membrane Potentials Considered as Diffusion Potentials," by Dr. E. B. R. Prideaux; (9) "Enzymes," by Dr. E. F. Armstrong, F.R.S.; (10) "The Relation of Certain Enzyme Actions to Tissue Differentiation and Tumour Growth," by Dr. K. G. Falk; (11) "Catalytic Actions in the System Copper, Copper-Oxide, Oxygen, and Gaseous Reducing Agent," by W. G. Palmer; (12) "Alumosilicates," by W. Vernadsky; (13) "The Chemistry of Hafnium," by Dr. G. Hevesy; (14) "The Utilisation of Volcanic Steam," by Senatore Prince Ginori Conti; (15) "The Biochemical Effect of Polarised Light," by Miss E. S. Semmens; (16) "Cotton Wax," by Dr. R. G. Fargher; (17) "The Absorption of Methylene Blue by Cotton," by D. A. Clibbens; (18) The Sulphonation and Nitration of Naphthalene," by Prof. H. E. Fierz.

Sept. 17. THE INSTITUTION OF RUBBER INDUSTRY, in the Kelvin Room, Engineers' Club, Coventry Street, W., at 8 p.m. "Rubber Floors and Rubber Roadways," by E. J. Edwards.

Sept. 17–18. THE IRON AND STEEL INSTITUTE. Autumn Meeting, to be held at Milan, in the Chamber of Commerce, commencing each day at 9.30 a.m. At the conclusion of the meeting visits have been arranged to Florence, Rome, Piombino, Leghorn, Genoa, and Turin.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

BRISTOL SECTION

The Bristol Section has issued a useful pamphlet containing a list of names of its officers and members, the rules of the Section and the programme of meetings for the 1923–24 session, from which we extract the following details:—

On October 4 J. F. Reid will read a paper entitled "An Outline of Rubber Manufacture," and on November 1, A. H. Bridges will speak on "Some Aspects of the Paint Trade, Fine-colour and Lake-making." The meeting on December 6 will be held jointly with the Institute of Chemistry, and a paper entitled, "Some Reminiscences of an Alkali Inspector," will be contributed by R. D. Littlefield.

In 1924 the first meeting will be held on January 3, when O. Jones will read a paper on "The Chemical Technology of Canned Foods." On February 7, the meeting will be held under the scheme for co-operation with the Chemical Society, and Profs. F. Francis and J. W. McBain will give an account of "Current Chemical Research at Bristol University." On March 6 there will be the general meeting and election of officers, and the following papers will be read:—"Combustion Control in Boiler Houses," by H. T. Ringrose, and "Fuel Economy Questions," by H. Womersley. It is proposed to hold the annual dinner jointly with the local section of the Institute of Chemistry in February. The meetings are held at 7.30 p.m., in the Chemical Department of the University, Woodland Road.

CORRESPONDENCE

THE ARTIFICIAL SEASONING OF WOOD

Sir,—In an article on the "Artificial Seasoning of Wood by the Ozone Process," which appeared in the December 30 number of your *Journal*, there is described in some detail a theory on the drying of wood which is used as casually as though it had been known and accepted for years, but it appears to be entirely new, and, so far as we know, it has no foundation in fact.

This theory is briefly as follows :—

The proper seasoning of wood consists in oxidising certain organic sap constituents.

If these constituents are not oxidised the wood will shrink during their subsequent oxidation and also absorb water on account of their hygroscopicity.

If these constituents are removed by steaming or boiling, the wood is satisfactory as far as shrinking and absorbing moisture are concerned, but it is brittle and lifeless, since the cells are left empty.

If, however, these constituents are oxidised and the oxidised products are left in the wood, no absorption of moisture, shrinking or swelling will ever take place and the wood retains its resiliency.

In startling contrast to this the facts are as follows :—

The proper seasoning of wood can be obtained by simply drying it with the least possible injury due to too rapid or irregular drying.

Such "organic sap constituents" are wholly mythical, and the absorption of moisture and the drying of wood (accompanied by the corresponding swelling and shrinking, respectively) are properties of the wood fibre itself.

There is an equilibrium between the moisture content of wood and the humidity of the air with which it is in contact, and this is all the theory that is required for the drying of wood.

No [seasoning process can transform wood so that it will not change its moisture content (and its volume) to correspond to the humidity of the air, although the equilibrium curve may be shifted slightly by certain conditions of drying.

The information available on the chemical composition of wood does not show the possibility of such substances being present in wood in sufficient quantity to affect the "life" or brittleness, and, in fact, there is no basis for deciding whether their *presence* or their *absence* would be more likely to make the wood brittle.

Most of these facts on the drying of wood have been known and used for a long time and have been available in the literature (see Tiemann's "The Kiln Drying of Wood"), so that it is astonishing to find such a different and fantastic theory announced without any mention of commonly accepted facts on the subject.

Aside from the general theory there are also many inaccuracies. The term "sap" should be limited to the circulating liquid in the sapwood only, but it is evidently applied to all moisture occurring in wood, since otherwise the theory of drying would apply only to sapwood. The classification of the sap constituents into "amylaceous substances" and "resinifiable substances" is questionable. The decomposition and disappearance of starch at 60° C. is remarkable. There are no usually employed mechanical, chemical, or microscopical methods for distinguishing between air-dried and kiln-dried wood. There are at present in operation commercial kiln-drying processes which produce seasoned wood fully as good as air-seasoned wood.

If we had seen statements of this kind made in a trade journal, in patent specifications or in the newspapers, we would not have taken the trouble to point out the mistakes, but articles appearing in publications like the *Journal* of the Society of Chemical Industry are supposed to be authoritative, and it would be a mistake to allow such inaccuracies to remain unnoticed. —I am, Sir, etc., L. F. Hawley,

In Charge Section of Derived Products

United States Department of Agriculture,

"THE REFEREEING OF SCIENTIFIC PAPERS"

Sir,—Improvements in the editing of scientific papers valuable to authors were advocated in the article published under the above title in *Chemistry and Industry* of July 11 ; readers also could benefit from changes within the scope of editorial authority.

Editorial insistence on an explicit usage of terms would aid the ordinary reader. A change or growth of connotation not officially sanctioned and recorded is most apt to lead to a mistaken interpretation. The worst confusion arises when individual writers put new meanings into old terms, which thus may acquire contradictory meanings.

Chlorine is said to be a "mixture" of chemically identical elements with diverse masses. According to the original significance of the word "mixture," chlorine should be separable by diffusion at a predictable rate. Experimentally the separation of the chlorine isotopes is, if accomplished, certainly much slower than for a "mixture" separated by any physical process ; it is assumed to be impossible chemically. As the main implication of the term originally was separability, this use to include the almost or quite inseparable is infelicitous. A "syndicate" of isotopes is a possible alternative ; the derivation implies unity of action, the common connotation is an undisclosed method of action and measure of cohesion.

Editorial rules for the term "electron" also are very desirable. Amongst the varieties discussed are valency, inner, cementing (colloidal) and shared electrons. Although neither matter nor the electron can be defined completely, the properties or attributes used in an investigation can be stated. If the attributes in different researches are incompatible, then the varying brands of electrons should be distinguished clearly. As originally conceived the electron had position, inertia and an invariable electric charge, the electric field being symmetrical and uniform in grade. In this field every electron would act on or "share" every other; the concept of a partial or restricted "sharing" is contradictory to that of a symmetrical field. A special term, *e.g.*, "amberon," derived like electron from amber, for an electron with a polarised field would make for clarity. For the "cementing" electron, an undeveloped concept, "amberguiton," suggests itself.—I am, Sir, etc.,

Manchester E. F. MORRIS

THE FIRST USE OF SYMBOLS

SIR,—I shall be greatly obliged if some of your readers will explain when chemical symbols and formulæ came into use. I find them sparingly used by Graham in 1833, and a list of the symbols of the then known elements is given by Berzelius (my edition is dated 1835), but many chemists in much later times seem to have made no use of them.—I am, Sir, etc.,

August 31, 1923 ANALYST

PERSONALIA

Mr. W. A. Davidson, formerly assistant chemist in the laboratory of the Dominion Public Health Department, Winnipeg, has been appointed director of the Dominion Health Laboratory for British Columbia.

The Canadian parliament has voted a life annuity of $7,500 to Dr. F. G. Banting, the discoverer of insulin, to enable him to devote himself entirely to research work.

Dr. V. L. Bohnson has resigned his post as Assistant Professor of Chemistry, in the University of Wisconsin, to join the staff of the Oldbury Electro-Chemical Co., Niagara Falls, N.Y.

* * *

With great regret we announce the death of Dr. E. K. Muspratt, in his ninetieth year. An obituary notice appears on another page.

We regret to announce the death of Mrs. H. Ayrton, whose name will be remembered in connexion with researches on the chemical arc.

The death is announced of Dr. M. P. C. Potvliet, chemist of the Dominion Sugar Co., and the author of papers on sugar refining, etc.

NEWS AND NOTES

UNITED STATES

The Absorption of Carbon Dioxide

In the course of work on the absorption of gases, the U.S. Bureau of Standards has obtained some interesting data on the absorption of oxygen in water and of carbon dioxide in solutions of sodium carbonate. It was found unexpectedly that carbon dioxide dissolved less rapidly in normal carbonate solutions than in pure water, despite the possibility of the formation of bicarbonates. To determine the effect of the viscosity of the absorbent solution on this phenomenon, determinations were made with aqueous solutions of sugar having the same viscosity as the sodium carbonate solutions, but the decreased absorption in carbonate solution still remained.—(*Chem. & Met. Eng., July* 30, 1923.)

Chromite in 1921

The U.S. Geological Survey reports that the total sale of domestic ore in 1921 was 282 long tons, equivalent to 245 long t. of 50 per cent. ore. Although this quantity is trifling as compared with that sold during the war, it is close to the average annual production from 1900 to 1913, inclusive, which was 232 t. Of the total quantity sold in 1921, 68 t. came from California and 214 long t. from Oregon. In spite of the large imports in 1920 and the large reserve accumulated, imports in 1921 were remarkably high, amounting to 81,836 long t., the result doubtless of the low prices, the average price, $8, being even less than the average of $9·56 in 1913. It is thought that a large reserve supply is available, perhaps enough for more than a year's consumption. The imports, were derived chiefly from British South Africa, 23,318 t.; Canada, 7554 t.; French Oceania, 35,108 t.; Greece, 8104 t.; and Turkey in Asia, 5822 t. The imports of chromium compounds were small as compared with the consumption. The apparent consumption of chromite during 1921 was 82,118 long t., which compares with 152,777 long t. in 1920. Sales of ferrochrome in 1919 and 1920, the only years for which figures are yet available were estimated at 15,763 long t. in 1919, and 16,606 t. in 1920. The quantity of 50 per cent. chromite required to yield this amount of ferrochrome, on the arbitrary assumption of no loss of chromium in slag, would be 31,700 long t. for 1919 and 33,400 long t. for 1920. The world's output of chromite in 1920 is estimated to have been 190,000 metric tons.

FRANCE

The Third Congress of Industrial Chemistry

Further details are to hand of the Congress which, as we have previously announced (*Chem. & Ind., p.* 818, 1923), is to be held by the Société de Chimie Industrielle from October

21-27. The Organising Committee has decided that the moment is opportune to treat important questions relating to agriculture, and has accordingly invited experts of various nationalities to deal with these questions in three conferences. Sir John Russell will speak on "The Relation between Soil Organisms and Soil Fertility," and Prof. Menozzi, director of the Higher School of Agriculture, Milan, will read a paper on "The Development of Agriculture" on October 22. On October 24, Prof. Lindet will describe the reconstruction of the sugar factories, distilleries and breweries. The task still awaits geologists and biologists of modernising and industrialising the methods of agriculture, and this aspect of the question will, it is hoped, be particularly emphasised at the meeting. As in former years all branches of chemistry will be represented at the meetings of the fifteen technical and economic groups of the Congress, of which the general recorder is, as at previous meetings, Monsieur Maurice Deschiens. Apart from national representation, scientists representing many foreign societies will take an active part in the work of the Congress. The Congress will be initiated on October 21 with a reception of the foreign delegates, followed by an artistic and musical evening. On October 22 and 23 the time will be devoted to the important conferences mentioned above and to the meetings of the technical groups, and on October 24 the closing meeting will be followed by a banquet under the presidency of Monsieur Chéron, Minister of Agriculture. Visits will be paid on October 25 to the food products factory of F. Potin and to the Ménier chocolate works, where Monsieur Ménier will offer a lunch to those attending. The excursion to Rheims on October 26 will include a reception at the Cathedral and a dinner offered by the Champagne producers, followed by a visit to the wine-cellars.

Members of this Society should be reminded that the French Society has offered, through the medium of its President, Monsieur Paul Kestner, a most hearty invitation to them to attend the meeting in Paris.

Standardisation

The *Journal Officiel* of July 8, contains a list of standards to be applied, within six months, to sheets, plates, tubes, bars and sections of light, strong alloys; to platinum and platinum alloys; to industrial zinc; and to various iron and steel products used in shipbuilding.

GENERAL

Low Temperature Carbonisation

The Fuel Research Board has recently issued a report (Technical Paper No. 7, H.M. Stationery Office, 9d.) entitled, "Preliminary Experiments into Low Temperature Carbonisation of Coal in Vertical Retorts," and containing an account of work carried out at H.M. Fuel Research Station, East Greenwich, with a set of four vertical retorts. These retorts were originally designed for high-temperature carbonisation, but it was considered that the experience gained by experiments with these retorts would help in designing retorts better adapted to low-temperature carbonisation. The new retorts have been completed, but trials have not yet begun and some time must elapse before any results can be published. This report has thus been issued as it was thought that an account of the preliminary work would be of value, especially the results relating to the distribution of temperature in the retort under various conditions of steaming.

Ramsay Memorial Department of Chemical Engineering at University College, London

The work of the Ramsay Memorial Department of Chemical Engineering at University College, London, will begin in October, 1923. This department has been instituted with the object of enabling young graduates in chemistry and engineering, who have already obtained a good training in the fundamental sciences of chemistry, physics and mathematics, to direct their studies and investigations towards the application of the principles of physical chemistry to the scientific design and operation of the apparatus and processes of chemical industry in general.

Mr. E. C. Williams, M.Sc. Vict., has been appointed Professor in charge of the department, and the University College Committee will shortly appoint an Assistant Lecturer, who must have had an engineering training. The commencing salary will be either £350 or £400, according to the previous training and experience of the man appointed.

British Standardised Steel Samples

The Iron and Steel Institute and the National Physical Laboratory issue the following standards:—No. 1, Sulphur ($S=0{\cdot}027\%$); No. 2, Sulphur ($S=0{\cdot}071\%$); No. 3, Phosphorus ($P=0{\cdot}029\%$); No. 5, Carbon ($C=0{\cdot}65\%$) Acid O-H Steel; No. 6, Carbon ($C=0{\cdot}10\%$) Basic O-H Steel. These samples are supplied, post free, at 21s. per bottle of 50 grammes, together with a certificate of standardisation. The samples can be obtained from The National Physical Laboratory, Teddington; or from Prof. C. H. Desch, Sheffield University; Dr. C. A. Edwards, University College, Swansea; Col. E. L. Johnson, Cleveland Technical Institute, Middlesbrough; or Mr. D. A. MacCallum, West of Scotland Iron and Steel Institute, 93, Hope Street, Glasgow.

Metallurgy in Luxemburg

Although the situation of metallurgy in Luxemburg had improved considerably during recent months, it is now greatly hampered by a shortage of coke. At Esh only 5 out 6 blast-furnaces are working, at Dudelange 4 out of 6, at Dommeldange 1 out of 3, at Beral 4 out of 6. The works at Esh are closed down, as are those of the Hadir coal at Rummelange. Altogether, out of 47 blast-furnaces only 26 are alight.

Blast-furnace Slag as Track-metal

After thorough investigation in the German materials-testing station at Dahlem the use of blast furnace slag as a track metal has been approved. Only such slags may be used as have been obtained in the form of blocks or bars. Special rules have been made regarding the production and use of such slags, in respect of their size, resistance to shock, permeability, and so on. (*Cf.* "Die Bautechnik," No. 9, 1923). The regulations supply a need, since not only are they a basis for the application of the metal to railway purposes, but the stipulated tests also provide a means of judging the suitability of slags as "metal" for other purposes.

REPORT

REPORT ON THE COMMERCIAL AND INDUSTRIAL SITUATION IN HUNGARY, DATED MARCH, 1923. *By* R. J. E. HUMPHREYS. *H.M. Commercial Secretary, Budapest. Department of Overseas Trade. Pp.* 38. *H.M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

The year was an exceedingly difficult one, and though an apparent improvement was to be seen (*cf.* J., 1922, 335 R), the actual daily life of the population did not improve. After an interval of industrial peace, extensive strikes occurred and at the date of the report 70,000 people were out of work.

Agriculture is the chief industry, the exports of agricultural products being an important source of income, and the preserved meat and vegetable canning trades are becoming important. Developments have occurred, however, in the engineering industry. The coal industry was eminently satisfactory in 1922; 741,000 tons of bituminous coal was produced, 605,000 t. being imported and 271,000 t. exported. Of lignite 5,615,760 t. was produced, 49,823 t. imported and 31,788 t. exported; 133,236 t. of coke was imported and 4767 t. exported.

The statistics show that during 1922, Hungary imported 3½ million t. of goods, valued at £25,540,000, compared with exports amounting to 1½ mill. t., valued at £14,000,000. In 1921 the figures were £23,257,000 and £12,050,000 respectively. The chief imports were textiles; coal formed 7 per cent. of the total imports in 1922, chemicals 2 per cent., iron and ironware 2 per cent., and mineral oils 1·7 per cent. The chief exports were wheat and rye flour 20·0 per cent., machinery and electrical materials 12 per cent., and iron and ironware 3·1 per cent. Most of the trade is done with Austria, Czechoslovakia and Rumania. It is anticipated that trading conditions will improve when Hungary is sufficiently stable to enter into commercial agreements with all countries; some are already in force.

REVIEWS

THE PHASE RULE AND THE STUDY OF HETEROGENEOUS EQUILIBRIA: AN INTRODUCTORY STUDY. *By* A. C. D. RIVETT, M.A., B.Sc. *Pp.* 204. *Oxford: The Clarendon Press,* 1923. *Price* 10*s.* 6*d.*

In this little book the author endeavours to provide the student with an introduction to the study of heterogeneous equilibrium which is based on a stricter application of the principles of the phase rule than is usual in most introductory text-books. The author's presentation of the subject is logical, and evidently the product of much thought and care. It should prove a valuable book for the student to read alongside Prof. Findlay's book on the same subject. It does not attempt to cover the same ground as is covered in Prof. Findlay's book by the description of the results of experimental studies of a number of important cases of heterogeneous equilibrium; but it has the compensating advantage that it includes clear explanations of complete space-diagrams which should help the student to obtain a broader view of the whole problem. A short but well-written chapter on "Some Thermodynamical Considerations" is one of the chief features of the book.

There are 118 figures in the book, which help very materially in understanding the subject matter. Only one small mistake has been noticed, namely in Figure 16, in which presumably the whole of the curve P_A P_B, should appear above the dotted horizontal line.

H. T. TIZARD

THEORETICAL CHEMISTRY FROM THE STANDPOINT OF AVOGADRO'S RULE AND THERMODYNAMICS. *By* PROF. W. NERNST. *Fifth edition, revised in accordance with the eighthtenth German edition by* L. W. CODD, M.A. *Pp. xx*+922. *London: Macmillan and Co., Ltd.,* 1923. *Price* 28*s.*

Since the fourth English edition of this work was published in 1916, very important advances have been made in that province which forms the common meeting ground of chemists and physicists, and these have necessitated an unusually thorough revision of the text of various sections as well as the addition of a considerable amount of new matter.

The general character of the book is so well known that a reference to the changes which have been introduced will amply suffice for the purpose of this review. For the most part, the new material has been selected with care, and having regard to the limitations of space, it may be said that a very considerable measure of success has been achieved in the presentation of the more recent discoveries.

The chapters on radioactivity, pp. 480-490, and on the molecular theory of the solid state, pp. 269-292, have been largely re-written, and significant additions have been made to the sections dealing with the structure of atoms, the applications of X-ray spectroscopy and the determination of molecular magnitudes. Attention may also be directed to the very clear exposition of the quantum theory, the applications of which are discussed in relation to the problem of the specific heats of solids, the determination of the Avogadro number and the interpretation of the energetics of photochemical change. As might be expected, the sections devoted to the Nernst heat theorem and its applications are admirable in their lucidity.

In the preface to the German original, the author claims that the theories which have been selected for discussion in the earlier editions have in nearly all cases justified their inclusion in the light of subsequent developments. It may be doubted whether such a claim can be put forward in the future. The theory of electrolytes propounded by Ghosh affords a case in point. This theory has been very favourably considered by Nernst, who describes it as affording the solution of a problem which has occupied the attention of investigators for a period of thirty years. Recent criticisms of the theory give an entirely different impression of the status of the Ghosh hypothesis, and the translator has found it necessary to add a footnote to the effect that the theory must be accepted with considerable reserve in the absence of further confirmation.

In the chapter on the kinetic theory, attention is directed to the equation of state propounded by Wohl, which is described as surpassing all previous formulæ in the accuracy with which it reproduces experimental results over a wide range. As an empirical formula, the equation of Wohl has undoubted merits, but in view of the more recent scrutiny to which the equation has been submitted, it appears very doubtful whether it can be regarded as having any satisfactory theoretical basis.

The doctrine of the equipartition of energy, inappropriately referred to as the theory of degrees of freedom, is subjected to severe condemnation. The author states that he has never been able to understand "that investigators of the first rank, like Maxwell, Boltzmann and W. Gibbs, . . . should have shut their eyes to the fact that the consequences of the theory were in many ways absolutely contradictory to experience, and that therefore the fundamental principles of the theory needed modification." So long as there is any vestige of doubt as to the way in which this principle should be applied to particular types of statistical systems, the dogmatic attitude implied in the above statement seems scarcely appropriate in a text-book of this type. There are undoubtedly differences of opinion on the matter.

Sundry circumstances serve to remind readers that the present translation is based on a German revision completed in 1920. The absence of any account of the important developments which are associated with the Lewis-Langmuir theory of atomic and molecular structure and the nature of chemical combination, and also of recent work on the kinetics of reactions in heterogeneous systems, may be cited as affording an indication of the gap between the present state of our knowledge in certain directions and that of the year of revision.

As a general text-book, the work of Nernst has, nevertheless, many unique and valuable features. Although it can no longer be said to deal adequately with all the branches of physical chemistry with which the advanced student is supposed to have some degree of familiarity, yet its qualities entitle it to be placed in the front rank as one of the sound and philosophic expositions of the outlines of general theoretical chemistry. The translator has produced a very readable version of the German original, and in this the particular merits of the author's mode of treatment of the subject matter have not been allowed to suffer in any way.

H. M. Dawson

Aluminium and its Alloys: Their Properties, Thermal Treatment, and Industrial Application. *By Lieut.-Col.* C. Grard. *Pp.* xxiii+184. *London: Constable and Co., Ltd.*, 1921. *Price* 17*s*. 6*d*.

In reviewing a translation the reviewer undertakes a double task, for he is called upon to appraise both the original book, and the work of the translator or translators. In the present case it is pleasant to be able to say at the outset that if Colonel Grard's book had to be translated the work could not have been better done than Messrs. C. M. and H. W. L. Phillips have done it. Serious errors in translation are singularly few, although one or two have crept in. One such error, which consists, apparently, in the rendering of the French word "soudure" as "soldering," instead of as "welding," which was almost certainly intended, has completely vitiated the sense of Chapter VI, Book I, Part II, which deals with the welding of aluminium. The text, however, runs remarkably smoothly for a translation, although, in the present writer's opinion, the first person plural, so beloved of French scientists and English first-year students, is ill adapted to the purpose it is here called upon to serve. That, however, is merely a matter of taste. Generally speaking, the translation is an excellent piece of work.

The book itself is extremely disappointing. It is not, as its title would imply, a text book on aluminium and its alloys, but an account of some researches carried out by the author, or by several French public testing laboratories on his behalf. The whole is divided into two books, to which are added six appendices, giving the analytical methods used in the course of the research, details of the mechanical tests carried out by the public laboratories referred to above, and a reprint of a paper by the author on the "Thermal Treatment of Duralumin."

Book I is devoted to pure aluminium, and is so full of mis-statements and inaccuracies as to be of no value at all. Two or three examples will suffice to justify this condemnation. Thus, for instance, Chapter I purports to give the physical properties of aluminium. It occupies a short page and gives values for six properties of which five are wrong according to recent determinations. Turning to the chemical behaviour of the metal, the following remarkable sentence is found :—"The explanation of this change (under the influence of chemical, physical or mechanical agencies) refers partly to indisputable phenomena and partly to hypotheses which probably have the advantage of lying very near the truth." This is followed by the statement that "air and ordinary water, acting alternately, have less effect than water alone." As it has been abundantly proved that oxygen is essential to the corrosion of aluminium, the foregoing statement might be said by the uncharitable to lie very near the truth.

In the sections devoted to the mechanical properties of the metal, the elastic limit of work-hardened sheet with a tensile strength of 11·43 tons is given as 11·11 tons per square inch, a figure which is likely to lead any engineer who relies upon it into serious difficulties. In the same section the author describes investigations, the object of which was to determine the time necessary to complete the process of annealing at various temperatures. He finds that at temperatures from 100° C.—300° C. an exposure of five minutes suffices, and this though he was aware of the work of Carpenter and Taverner (cited on a subsequent page), who have shown conclusively that at some of the temperatures within this range (*e.g.* 200° C.), exposure for many years is required before annealing is complete!

The reader who has met statements of this kind in Book I, is not likely to commence the reading of Book II with much confidence. Should he do so, he will be met near the outset by a statement that an alloy containing 3·1 per cent. of copper and 11·60 per cent. of zinc, has a tensile strength of 6·98 tons per square inch. Now the composition of the alloy in question is almost exactly that of the most popular English casting alloy, L5, for which the British Engineering Standards Association specification demands a minimum of 11 tons. A little later he will find the statement that the results produced by quenching the series of alloys of which duralumin is the best known, are "due to the presence of the magnesium or of the magnesium and zinc." This statement ignores altogether the important rôle assigned by recent investigators to the silicon and copper, which are regular constituents of these remarkable alloys.

However, enough has probably been said to indicate that this is no book to place in the hands of students, whilst the advanced worker is little likely to derive any benefit from its perusal.

RICHARD SELIGMAN

RAYS OF POSITIVE ELECTRICITY AND THEIR APPLICATION TO CHEMICAL ANALYSES. *By* SIR J. J. THOMSON, O.M., F.R.S. *Second edition. Pp. x+237. London : Longmans, Green and Co.*, 1921. *Price* 16*s*.

This is a new edition (the second) of Sir J. J. Thomson's well-known book, and gives a very full account of all the new work that has appeared since the date of the first edition (1913). This applies especially to the work of Aston and Dempster, and to the author's own recent work. The application of positive rays to chemical analysis and the bearing of investigations by this method on the nature and structure of atoms and molecules are fully discussed. The book is not only of fascinating interest for every student of science, but also of the utmost importance for chemists. Probably the time is very near when every chemical laboratory will *possess* a positive ray outfit. Already one can say that every University Chemical Laboratory *requires* (even though it does not possess) one, and the same statement applies with equal force to important industrial research laboratories.

F. G. DONNAN

DICTIONARY (ENGLISH-CHINESE) OF THE COMMON ELEMENTS AND THEIR CHIEF COMPOUNDS. *By* PROF. J. L. HOWE, M.A., *and* P. P. PAN. *Pp. iv+60. Shanghai, China : Commercial Press, Ltd.*, 1923.

In view of the increasing output of scientific literature written in Chinese or Japanese characters, a need has arisen for some form of technical dictionary. An attempt to meet this need has been made in the pamphlet under review, which gives, both in English and in Chinese, the names, occurrence (*i.e.*, whether a commercial or laboratory product, or an ore), formula, molecular weight, crystalline form and solubility in common reagents of the commoner elements and their compounds in tabular form. The list of atomic weights needs revision (that of antimony appears as 102·2 instead of 120·2), and although spelling such as "iodin," "sulfid," "sulfate," etc., is doubtless accepted in the United States, the propriety of phrases such as "Antimony Sulphide-tri" or "Chromium Chlorid (ic)" is questionable. The pamphlet, though very limited in scope, should prove useful to those who desire to ascertain the Chinese ideographs for common chemicals, as well as to Chinese students, for whom it is primarily intended.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Aug.* 30)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Algeria ..	Metals, sugar	258, 259
Brazil ..	Drugs, chemicals ..	267
British India	Lubricating oil, electric cable (tender) ..	*
Canada ..	China clay	245
,, ..	Fire bricks	11947/E.D./M.C./2
Chile ..	Oil, iron (tender) ..	8589/F.L./G.C./2
,, ...	Manganese steel (tender)..	8588/F.L./E.C./2
Cyprus ..	Leather	247
Far East ..	Metal, iron and steel bars	261
Morocco ..	Steel (tender) ..	11352/F.E./E.C.
Norway ..	Raw hides, salt, soda	252
Poland ..	Chemicals	254
Rumania ..	Lead tubes (tender) ..	11368/F.E./E.C./2
Switzerland	Drugs	256
United States	Ferro-alloys, china clay, fuller's earth ..	264
,, ,,	Portland cement, ammonium sulphate, fish oils	265
,, ,,	Galvanised sheets, tinplate	20293/1/F.W.

* Director-General, India Store Dept., Branch No. 10, Belvedere Road, S.E. 1.

TARIFF CUSTOMS EXCISE

British India.—The Indigo Cess (Repealing) Act, now passed, repeals the Acts providing for the levy of a cess on exports of indigo.

New Caledonia (*French*).—A modification of import duties has been applied to oils, resin, spirits of turpentine, calcium carbide, hydrogen peroxide, sulphuric acid, rubber belts and packing.

San Salvador.—Perfumery is now dutiable at the old rate of 40 centavos (gold) per kg.

South Africa.—Imported patent and proprietary medicines of undisclosed composition and for general sale are dutiable.

Southern Rhodesia.—A rebate of the duties has been granted on methylated spirits, medicinal preparations, acetic acid, and perfumed spirits.

COMPANY NEWS

MINERALS SEPARATION, LTD.

At the 18th annual general meeting held on August 29, the chairman, Mr. F. L. Gibbs, said that although progress was slow, the company was steadily gaining a worldwide position of great strength in the coal and metalliferous industries that would amply repay them in future. The department for dealing with the cleaning and briquetting of coal would probably be the first to produce income on a large scale. Last year it was intended to construct a large briquetting works on a site acquired by the Powell Duffryn Steam-coal Co., Ltd., and Minerals Separation, Ltd., at Newport, but as the French Powell Duffryn Co. had decided to erect a large plant at Nantes, it was decided to await the completion and operation of this plant before erecting that at Newport. The working of the Nantes plant had proved their estimates of costs to be right, and arrangements for the erection of the plant at Newport could now be made. The hardness of the briquettes made by the new wet-briquetting system satisfied the standard demanded by the French State Railways, and in addition this fuel was purer than other patent fuel, for it was cleaned of all free ash, a factor which, in combination with the physical structure, was probably responsible for the large calorific power of these briquettes. It was anticipated that in 1925 plants utilising the company's processes for briquetting coal would be producing over 10,000 tons or even more per day. Not only would returns be received in royalties from these processes, but the company would be part owners of many of the works utilising them. Several collieries in this country and in Spain were utilising these processes for cleaning coal for coking, plants were being erected in France, Belgium and Germany, and the use of the processes was being considered in India.

A plant to test the ore-reduction process for the treatment of oxidised silicate and carbonate copper ores had been erected in Australia and another was being erected in the United States. If the plant erected by the Bwana M'Kubwa Copper Mining Co., Ltd., in Northern Rhodesia, gave successful results, the company had in conjunction with others the right to underwrite an issue of further capital by the Bwana Company to be used, in part, for the erection of a large plant. The Bwana Mine contained already over 8,000,000 t. of good grade copper ore, and the success of the process should make the company extremely profitable. With the resumption of active operations at the end of the Broken Hill Strike, there was every prospect that the company's Australian business would be profitable for many years. He hoped that later in the year he would be able to announce that their new metals processes, especially those applied to copper, had been as successful as the processes used for treating coal.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Trade generally continues very flat with no sign of any upward movement. Home trade enquiries are common but there is no volume of business. Export trade in heavy chemicals continues comparatively good. Manufacturers have reduced the price of Borax Commercial by £2 per ton.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d.—5s. per carboy d/d. Quiet in textile circles.
Acid Nitric 80° Tw.	£23 per ton.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.—£5 per ton. Export demand continues good and manufacturers are in many cases fully sold for some time ahead.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8—£10 per ton, according to grade. Market quieter.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% P.O. Fairly regular demand.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5—£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Market well maintained and a better enquiry for spot parcels is experienced.
Crude 60's	3s. 3d.—3s. 4d. per gall.
Acid Cresylic—97/99	2s.—2s. 5¼d. per gall. Fair business.
Pale 95%	1s. 11d.—2s. 4¾d. per gall.
Dark	1s. 10d.—2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price.
Anthracene Oil—	
Strained	8¾d.—10d. per gall. Supply short.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	1s. 1½d. per gall.
Standard Motor	1s. 6½d. per gall. delivered buyer's works.
Pure	2s. per gall. delivered buyer's works.

Toluole—90%	1s. 8d.—1s. 10d. per gall. Market quiet.
Pure	2s. per gall.
Xylol	3s. 3d. per gall., according to quality.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9¾d. per gall. Fair enquiry.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 4d.—1s. 6d. per gall.
Solvent 90/190	1s. 4d.—1s. 7d. per gall. Fair enquiry.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Supply short.
Whizzed or hot pressed	£11—£12 per ton. Quiet.
Naphthalene—	
Crystals	£21 per ton.
Flaked	£17 10s. per ton.
Pitch, medium soft	132s. 6d.—145s. per ton. Market quiet.
Pyridine—90/140	19s.—20s. per gall. Market very strong.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic. tech.	1s. 8d.—1s. 9d. per lb.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works. Price hardening. Large export demand.
Aniline Salts	9½d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 2d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Prices firm with a good steady demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	2s. 11d.—3s. per lb. Market rather firmer.
Acid, Benzoic	2s. 3d. per lb. Supplies more plentiful, but price maintained.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 5½d.—1s. 6½d. per lb., less 5%. Supplies in excess of demand.
Acid, Gallic	3s. per lb. for good white with slight reduction for quantity.
Acid, Pyrogallic, Cryst.	5s. 9d. per lb. For large orders 5s. 6d. is accepted.
Acid, Salicyclic	2s.—2s. 4d. per lb. Market firm and prices well maintained.
Acid, Tannic	3s. per lb.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market continues weak.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 5d. per lb. Market very quiet.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz.
Barbitone	18s. per lb. Inclination for price to fall.
Benzonaphthol	5s. per lb.
Bismuth Salts	A steady market.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides	There are still heavy stocks here to be realised, so that higher prices are not likely at present.
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.
Chloral Hydrate	3s. 9d. per lb. for duty paid. Improved demand.
Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	Can now be imported free from duty. Spot supplies very scarce and prices erratic from £100—£110 per ton. Lower prices for forward delivery.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	3s. 6d. per lb. Prices easier, sales slow.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.

Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality & quantity.
Menthol	45s. per lb., less 2½%. Market rising owing to speculation.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 3d.—2s. 6d. per lb. according to containers.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid: Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9d., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 6d. per lb.
Paraldehyde	1s. 4d. per lb. for quantity.
Phenacetin	6s. per lb. Sales steady.
Phenazone	7s. per lb.
Phenolphthalein	6s. 6d. per lb. Temporarily in short supply.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s.—3s. 6d. per lb., according to quantity.
Potass. Iodide	15s. 8d. per lb. Good demand. Steady market.
Potass. Metabisulphite	5d. per lb. Spot value somewhat lower.
Potass. Permanganate	9½d. per lb. for large quantities.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. in bulk packages. Steady demand.
Resorcin	5s. 6d. per lb.
Salol	3s. per lb. Demand small, price firm.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 3d. per lb. Continental prices are being maintained.
Sod. Citrate, B.P.C. 1923	2s. 3d. per lb.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	Powder 2s. 5d.—2s. 7d. per lb., and Crystal at 2s. 7d.—2s. 9d. per lb. Prices firmer and likely to advance.
Sod. Sulphite, anhydrous	£27 10s.—£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25—£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. 9d. ,, ,,
Amyl Butyrate	7s. 6d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	2s. 9d. ,, ,,
Benzyl Benzoate	3s. 3d. ,, ,,
Cinnamic Aldehyde Natural	18s. 6d. ,, ,,
Coumarin	18s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	15s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	35s. ,, ,, Advanced.
Geraniol	5s. 6d.—12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. 6d. per lb.
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	21s. ,, ,,
Methyl Anthranilate	8s. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Xylol	11s. ,, ,,
Phenyl Ethyl Acetate	20s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Safrol	2s. 1d. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	22s. 3d.—23s. 6d. per lb. Firm with steady demand.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	29s. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4¾d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 2d. ,, ,,
Ceylon	3s. 9d. ,, ,,
Clove Oil	8s. ,, ,,
Eucalyptus Oil 70/75%	2s. 4d. ,, ,,
Lemon Oil	2s. 10d. ,, ,,
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	12s. per lb.
Otto of Rose Oil—	
Bulgarian	33s. 6d. per oz.
Anatolian	24s. per oz.
Palma Rosa Oil	20s. per lb.
Peppermint Oil—	
English	80s. ,, ,,
Wayne Country	13s. ,, ,,
Japanese	9s. ,, ,, Market rising owing to speculation.
Petitgrain Oil	7s. 3d. per lb.

TRADE NOTES

Trade Information

Technical Advertising.—Lavoisier once pointed out that facts, to be properly understood, must be properly expressed. In an interesting and well-produced booklet, the Technical Advertising Service, of 44, Bedford Row, London, W.C. 1, utilises Lavoisier's words to show the value of technical advice to the advertisers of technical products. As the difference between general and technical advertising is perhaps not sufficiently understood, this pamphlet should prove of value to those who have to market chemical and allied products, a field in which the "Service" has specialised.

Photography for Commercial Purposes.—We have received a copy of *The Professional Photographer*, which contains a suggestive account of the use made of photography by W. and T. Avery, Ltd., Birmingham, in advertising their weighing, testing and counting machines. As photographs are being increasingly used for propaganda for a wide range of products and other advertising work, it will be of interest to state that copies of the article can be obtained by applying to the Wratten Division of Kodak, Ltd., Kingsway, W.C. 2.

The French Chemical Market

The heavy chemical market in France was fairly quiet during August, and no great fluctuations were noted in prices of the chief products. The market is, however, active and certain factories are finding difficulty in keeping up regular deliveries. The following prices are quoted:—Sulphuric acid (53° Bé), 16·50–17 fr., 66° 27–28 fr.; nitric acid (30°), 130—132 fr.; hydrochloric acid (20—21°), 12—16 fr.; ammonia (22°), 110—115 fr.; caustic soda (76—77°), packed, 110 ft. For secondary chemical products, orders arrive regularly and prices vary very little. Despite the calm relatively usual to the glass industry in summer, orders are being received. Shortage of supplies of bichromates and sodium sulphide is felt in the tanning industry. There is a firm demand for many dye wares, and importation from England and Switzerland is taking place. Orders for dyes are scarce, and certain indispensable raw materials have reached high prices owing to their scarcity. Prices of products for the bleaching industry remain unchanged. There is a poor demand for glues and gelatins.

German Research on the Manuring of Forests.—The utility of manuring forests by means of mineral manures is still an open question, possibly because the matter has been tested from the wrong standpoint. In general the soil is chiefly deficient in nitrogen, so that the addition of potash and phosphates would be useless, whereas as soon as nitrogen is provided in an assimilable form astounding results are obtained. Comparison of pine trees grown for twenty years with and without nitrogenous fertilisation showed the growth of the manured trees to be on the average nearly three times that which had not been manured. The manuring was effected either by lupin plants or by surrounding the trunk with brushwood of broom or pine. The question of stimulating the growth of trees deserves attention in consideration of the present timber shortage.

Dr. W. A. Dyes, editor and author of the International Handbook on the Chemical and Allied Industries of the World, informs us that he is now endeavouring to complete the second volume of the "Handbook," in which he hopes to include a limited number of illustrations of works, etc., characteristic of each country. Those who wish to take advantage of this offer should send photographs or blocks of the size 4 by 3½ or 7 by 4 inches to Dr. W. A. Dyes, Berlin-Wilmersdorf, Landhausstr 9.

Erratum.—On p. 829, col. ii., of the issue of August 31, second paragraph, line 12, for "compound (usually alkaline)," read "compound, usually aniline."

Vol. 42 NEW SERIES LONDON, SEPTEMBER 14, 1923 No. 37

EDITORIAL

THE publication of a book on Ink by Mr. Ainsworth Mitchell reminds us that probably some little injustice has been done to him in this periodical. Some time ago we received an article on pencil marks and the history of the use of the pencil which in due course we published. Mr. Mitchell wrote stating that this article was very largely a paraphrase of his own work and that the source should have been suitably acknowledged. This letter was duly published and as our contributor has not replied the presumption is that Mr. Mitchell has a genuine ground of complaint. The editors of weekly—and we suppose daily—papers have in many cases neither the necessary knowledge to identify the sources of information of the numerous articles on many different branches of human knowledge, nor the time to hunt these up or to submit them to those who are reputed to be experts. They are, to this extent, at the mercy of their contributors and sometimes become their victims. We have received, and printed, communications from some who appeared to put forward unorthodox views, from others who seemed to combine elementary science with a vivid imagination, and from some even whom we suspected to be endeavouring to perpetrate mild hoaxes. Such matters cause us neither anxiety nor regret. But when the work of one person is made use of, even when put into different language, it is usual to indicate the source of it, and it is far more important to do what is usual than to do what each one considers to be suitable. For this reason, and probably no other, we wear collars, we shave in our youth and go bald in the prime of life. We ourselves are studiously conventional and though our own editorial conscience is untroubled we feel that Mr. Mitchell may reasonably be dissatisfied. As our contributor has, whether by reason of holidays or any other reason, given us no explanation we feel justified on his behalf in stating that if by some mischance the usual courtesy has not been observed the omission is much regretted; we trust that he and all others will in future remember this point.

We print in this issue an important article by Professor G. T. Morgan on the dyestuff industry in this country. The state of this industry presents an acute and difficult problem for the consideration of those who control our national well-being. The interest of the consumer is to have cheap dyes from the cheapest source where they can be satisfactorily made. The interest of the manufacturer is to have a reasonable profit on the manufacture, regard being had to our depressed trade, to high prices, high rates of wages and high rates and taxes. The interest of the State is to encourage employment both in the case of the consumer and the manufacturer and also to encourage the development of a successful chemical industry in this country. The reconciliation of these conflicting interests is no easy task. Everyone engaged in business knows that the inflation of foreign currencies, if continued for a considerable time, tends to national insolvency, but that while the inflation is continuing the foreign manufacturer is able to export at a price which is impossible for a country which conducts its finances more prudently. The Germans, the Italians and some other manufacturers can at the present time undersell us in very many commodities. The present condition of the world is wholly exceptional and remedies are suggested and tried, which are appalling to those whose political articles of faith were firmly implanted a score of years ago. But we think we are hardly overstating the case if we say that no country can in the future be a great industrial one and reasonably secure from the horrors of invasion unless it has a flourishing chemical industry. Chemistry will play a more and more important part in manufacture, not only the simple chemistry of the heavy trade, and the more complex chemistry of the fine variety, but also chemistry complicated to an extent hitherto undreamed of. British chemistry as a whole requires a flourishing dyestuff industry here, and if we as a nation really believe this we shall get it. Noteworthy as the progress has been, scientific research alone is insufficient protection.

THE NEW DYESTUFFS INDUSTRY OF GREAT BRITAIN

By Prof. GILBERT T. MORGAN, D.Sc., F.R.S.

The development of the synthetic colour industry has rightly been regarded as one of the romances of modern science, and this dramatic history assumed a tragic aspect for Great Britain and her Allies in 1914, when it was tardily discovered by the Governments concerned that the predominance of Germany in this branch of applied chemistry meant an overwhelming advantage to the enemy in the production of munitions of war. This intimate connexion between dye-production and the manufacture of high explosives was well known to the small group of English chemists who had devoted themselves to the study of coal-tar products, but the warnings of these experts were entirely disregarded by the superior folk who then, as now, affected to repudiate the truth of the old adage, *Si vis pacem, para bellum.*

It is only too evident that the terrible lessons of the war are being rapidly forgotten by our politicians, without distinction of party, and it is, accordingly, of national interest to survey the changes which have recently been effected in our capacity for the production of dyes and intermediates, bearing in mind the fact that the plants needed for these peace-time requirements would be relied on, in an emergency, for the manufacture of war materials.

Pre-war Period

In the twenty years preceding 1914 the manufacture of synthetic colours was carried on to a limited extent in this country by some eight firms, the largest of which had a share capital of the order of £200,000, but several of the others were on a much smaller financial scale. In many cases the plant was defective and ill-adapted to the purpose of dye-making. The number of chemists employed in supervising the processes and in research work was quite insufficient and the laboratory facilities for these workers were very inadequate. The generally accepted statement that 20 per cent. of our requirements in dyes was then met by the home production of colours is probably an unduly favourable estimate, inasmuch as even this restricted manufacture was to a considerable extent dependent on foreign intermediates which were merely assembled here to be converted into finished dyestuffs.

From time to time the statement occurs in the popular press that synthetic colour-making is an English industry which the Germans stole from us. This, however, is a totally erroneous view to take of the situation. It is true that the first pioneering discovery was made in England, and that certain of the older and simpler coal-tar dyes were manufactured in this country earlier than in Germany. But the fact remains that the great developments, including the establishment of the large Rhenish colour works, were due entirely to German chemists and industrialists. With the aid of large staffs of highly-qualified chemists and other well-trained scientific workers, entirely new intermediates and colouring matters were discovered and produced on a commercial scale, so that in 1914 the manufacture of these complicated organic chemicals was a well-established German monopoly. As an outstanding example of this supremacy it may be mentioned that at this epoch the whole of the vat dyes, including synthetic indigo, were the products of continental firms, and that no attempt had then been made by British manufacturers to produce either these materials or effective substitutes.

Chemists and engineers, working in close co-operation in the German factories, over a period of fifty years, had developed a technical skill in the manufacture of coal-tar products which was largely lacking in this country. Even the inorganic heavy chemicals required in these industrial syntheses were not procurable in sufficient quantities or at reasonable prices. Fuming sulphuric acid, chlorine, sodamide and sodium hydrosulphite were either too costly for the colour-maker or quite unobtainable. Special large-scale appliances for fractional distillation under reduced pressure or for digestion of reagents at high temperatures and under high pressure were not manufactured in this country. Of the few autoclaves then in use by English firms the majority were supplied by the firm of Krupp, and at the outbreak of war much of the dimethylaniline required in the manufacture of tetryl, an important military high explosive, was produced in these Krupp vessels. Even the simpler and more generalised factory plants were deficient in capacity, as was seen when the sudden demand arose for enormous quantities of TNT.

In consequence of these restrictions the few chemists engaged by English firms had no opportunity of gaining practical experience in the large-scale production of the more complicated intermediates and dyes. On the other hand, the dye users were lulled into a false sense of security and were offered every inducement to employ German rather than English colours, even when the latter were procurable. The agents and technical experts of the powerful German syndicates were always at hand to impress the British dyers and printers with the desirability of preferring German dye-wares. This campaign of peaceful penetration was only too successful. Those of the English dye-makers who still endeavoured to compete against their powerful continental rivals were in low water financially, whereas other firms, which, to a large extent, had become distributing houses for German colour-makers, found it much more lucrative to blend foreign dyes than to manufacture their own. Colour faking had become more profitable than dye-making.

The war revealed, as in a lightning flash, the abyss into which the pre-war British dyestuffs industry had fallen, and the next phase in the development of the home colour-trade is the history of a desperate attempt to establish an entirely new dyemaking industry of sufficiently comprehensive character to render the users independent of foreign supplies.

The War Period

This creative task, difficult enough in normal times of peace, was rendered infinitely more complicated by the circumstance that the activities of the newly-erected colour works were largely diverted to the manufacture of service explosives and materials for chemical warfare. Nevertheless, considerable extensions were made in dye-production, and, in addition to supplying suitable dyes for all our naval and military requirements, the British makers manufactured sufficient colour to dye the uniforms and accoutrements of the French and other Allies, whose resources had been diminished by invasion.

Chief among these wartime developments was the formation of the national company (British Dyes, Ltd.), which, in the first instance, was formed by taking over the old-established firm of Read Holliday and Sons, of Huddersfield. Subsequently, an amalgamation was effected with Levinstein, Ltd., of Blackley, a progressive firm which had previously absorbed Claus and Co., Manchester, and had acquired the German-owned synthetic indigo works at Ellesmere Port. The merger company has now been in operation for several years under the title of the British Dyestuffs Corporation, Ltd., an organisation comparable in financial strength with one of the large German combinations.

Meanwhile, a remarkable advance had been made in the direction of vat colours. The Sundour Fabrics Co., of Carlisle, under the direction of Mr. James Morton, had up till 1914 been large users of the modern fast vat dyes, and faced with an entire stoppage of German supplies this firm had, in 1915, begun to experiment on the manufacture of these colours. This audacious attempt on the part of dye users was very successful, and the enterprise, under the name of Scottish Dyes, Ltd., now owns two colour works at Carlisle and at Grangemouth.

In the pre-war period, the British Alizarin Co. manufactured alizarin red and a few other dyes of this series under a convention with the German makers. The war freed the firm from these restrictions, and in its new works at Trafford Park this undertaking now deals with the production of a wide range of colours based on anthraquinone.

The firm of L. B. Holliday and Co., starting at Huddersfield in 1916 as manufacturers of picric acid (lyddite) by a new process, have since developed into a dye-making enterprise covering a wide field of production.

Another German-owned factory situated at Rainbow Port, on the Manchester Ship Canal, was acquired by Messrs. Brotherton, with the result that the company is in a position to carry on the manufacture of colour from coal tar to the finished dye. This firm, which specialises in mordant colours and especially those used on a chrome basis, has also established in this country the large scale production of sodium hydrosulphite, a chemical essential to modern vat dyeing.

Mention should be made of the fact that the Gas Light and Coke Co. and the South Metropolitan Gas Co. now carry the purification of certain coal-tar crudes to a far higher degree of refinement than before 1914. These large gasworks also produce some of the more widely used coal-tar intermediates.

Altogether there are now upwards of twenty firms engaged in the manufacture of dyes and accessory products, with the result that during the later years of the war the requirements of the dye users were largely met by home-made colouring matters, with the exception of certain special dyes imported by the Swiss makers.

During the war period the shortage of dyes was acute and prices were very high. It is not surprising, since everything had to be improvised, that the new dye-makers concentrated on producing the desired colours at all costs without going closely into the matter of economical production. Plants had to be extemporised and experience gained by factory trials under entirely new conditions. Many of the requisite colours were soon forthcoming in sufficient quantities, although at first the methods of production were uneconomical and, moreover, the products were not always uniform as regards strength and purity of shade. Yet so great was the demand that dye consumers gladly accepted these experimental batches of colour even at high prices. It is not apparent that by doing so the users were appreciably hindered in their business, for generally they contrived to pay their dividends even with the heavy prices for colour then ruling.

The Post-War Period

The foregoing conditions were prolonged beyond the Armistice by the industrial boom which then developed, but with the passing of this period of trade inflation new conditions of international competition arose. Cheap foreign dyes again became available, largely as the result of the Sankey judgment, which flooded the country with considerable quantities of these imports.

The prices of dyes, which had risen continuously from 1914 until 1920, now began to fall, and this tendency still prevails at the present time.

The Present Capacity for Dye Production in Great Britain

As already mentioned, upwards of twenty firms are now engaged in manufacturing intermediates and dyestuffs with a total productive capacity far greater than that possessed by the few pre-war factories. This increase has resulted not only from the extension and enlargement of older works, but also by the erection of entirely new factories, and if all these works were fully employed it is estimated that they could produce more than 40,000 tons of dyewares per annum. This mass production of colour would probably more than suffice for the needs of home consumers even in a period of expanding trade, and it is evident that if dye manufacturers are to reduce their overhead charges to the minimum by working at full capacity, they must increase their export trade in dyewares. Some extension would result from an increased demand from the Dominions and British Colonies. Any stimulation of this demand by a preference for British-made dyes would be of inestimable value in decreasing to all consumers the cost of these products. It is worthy of note that Australia, like Great Britain, has adopted the policy of limiting the importation of foreign dyes to those which are unobtainable from British makers.

A well-established dye industry, secure in its home and colonial markets, would probably be in a position to sell its surplus products at economic prices in foreign markets, and it is only by such a comprehensive scheme of home and overseas trade that the community can reap the full benefit of the large additional dye plants established during the last eight years either by the State-aided company or by private enterprise.

The Range of Post-War Intermediates and Dyewares

It cannot be too strongly emphasised that our present dye-producing industry is essentially a new development, still in its infancy, for its beginnings only go back about eight years. During its short lifetime the advances made are little short of revolutionary. Indispensable intermediates which had never before been made in Great Britain are now produced in large quantities and of superlative quality. This noteworthy achievement is the result of the joint labours of chemist and chemical engineer. The successful preparation of these complicated organic chemicals in the research laboratories has been followed by expensive but vitally important trials on a semi-works and then on a factory scale. Special plant has had to be devised, and older apparatus has received important modifications to meet the increasingly stringent demands of the modern colour-maker.

Vat Dyes

Perhaps the most striking example of this phenomenal progress is shown by the vat dyes, a group of colouring matters which includes synthetic indigo and the modern vat colours discovered on the Continent since the beginning of the present century. In 1913 the British production of these extremely valuable dyes (excluding indigo) was *nil*, whilst in 1922 it exceeded 82 tons, being about 40 per cent. of the total home consumption of these colouring matters. This immense improvement redounds to the credit of the chemists and engineers concerned, for it consists not merely in working out complicated syntheses in the laboratory but in designing entirely new plant for the carrying out of difficult and dangerous operations on a manufacturing scale.

These mechanical appliances include large size works autoclaves capable of withstanding high pressures, ammonia-recovery plant and special filtration apparatus adapted for the collection of the costly chemical products. Several British engineering firms now specialise in the construction of chemical plant and a new profession, chemical engineering, has come to the front in solving the difficult problems of the economical manufacture of dyes and other chemical products.

The Krupp autoclave has now been replaced by well-designed British types, and a battery of the latter appliances which has recently been installed at the Grangemouth section of Scottish Dyes, Ltd., possesses all the latest devices for efficient working and regulation, coupled with adequate safeguards for the workers who control these high-pressure operations.

The intricate character of vat dye production is illustrated by the fact that in the production of 30 of these colouring matters by the Scottish firm, 290 intermediates are required, and these are all produced in the two works by a staff of about 200 operatives. Thirty chemists are engaged by this company either in supervising the works operations or in carrying on researches on vat colours and allied products. Of the intermediates required in this industry one of the most important is phthalic anhydride, which is manufactured on a very large scale at Grangemouth by the aerial oxidation of naphthalene with the aid of a special catalyst. This very efficient process, which furnishes phthalic anhydride of chemical purity, is entirely under electrical control; the whole installation constitutes a remarkable feat of chemical engineering representing an important technical improvement over the oleum and mercury-catalyst method practised at the Badische Anilin und Soda-Fabrik.

Three other firms, including the Clayton works of the British Dyestuffs Corporation (formerly Claus and Co.), are now engaged in the manufacture of vat dyes, and owing partly to this internal competition and partly to economies discovered in the course of manufacture, the prices of these colours have fallen considerably since 1920. The price of British indanthrene blue alone is now round about eight shillings a pound, but it has been calculated that, owing to the disparity in the exchanges, this colour could be made in Germany at prices ranging from 1½d. to 6d. a pound! It must, therefore, be obvious that without the protection afforded by the Dyestuffs Act the British vat industry would speedily cease to exist.

Before the war there was in England a camouflaged production of synthetic indigo carried out at Ellesmere Port by Meister, Lucius and Bruning in order to comply with the requirements of the Patent Act of 1907. But, unfortunately, the benefits of this statute were nullified by a legal decision, given shortly after the Act became operative, according to which it was held that the statutory provisions were complied with if any one of the processes of the patent were carried out in this country. Accordingly the German firm brought over the penultimate intermediate for indigo synthesis and carried out only the final steps in their English factory. When the Ellesmere Port works were taken over by Messrs. Levinstein in 1917, the process for indigo production was worked out in its entirety, and at present the Dyestuffs Corporation is turning out indigo at 1s. per ℔. But when the British Government takes reparation indigo, and credits Germany with an amount equivalent to the selling price in that country, the price works out at 2d. per ℔., which is approximately one-quarter of the cost of the raw materials of indigo production in this country. Again it is clearly obvious that the British industry cannot compete against competition of this exceptional character.

It is, however, certain that, if fully employed, the Ellesport Port factory could supply all British requirements, for in 1922 it manufactured over one million pounds weight of indigo, or rather more than the amount imported during the same year.

One of the problems still awaiting complete solution is the manufacture of the important sulphur vat-colour, hydrone blue. It has been prepared here on a small scale, but the colour has not yet been put on the market by British makers. The starting point in this manufacture is the coal-tar product, carbazole, which before the war was not isolated in this country from the anthracene fraction of coal-tar distillation. At present it is being produced of superior quality by at least three firms, including the South Metropolitan Gas Co., the Gas Light and Coke Co., and Messrs. Hardman and Holden, Ltd., the last-named firm also preparing in a state of purity acenaphthene, another coal-tar product entering into the production of certain vat colours. These developments are important steps in the direction of increasing our range of British-made colours.

Azo-Dyes

The azo-dyes constitute the largest section of synthetic colours and in this wide field it may be said that the chief problem is the manufacture of intermediates. The conversion of these materials into colours through the agency of the diazo-reaction is a process which generally proceeds without difficulty when the appropriate intermediates are available. Before the war these substances were to a large extent manufactured in Germany, but at present nearly all the important intermediates are produced on a large scale in British factories, and in many instances by more than one firm. For example, the intermediates derived from naphthalene such as the naphthols, naphthylamines, dihydroxynaphthalenes, gamma acid, H acid, J acid, chromotropic acid and β-hydroxynaphthoic acid are all obtainable from British sources in a state of purity often excelling in this respect the German products of the pre-war period.

Aniline and its homologues were made so efficiently in this country before the war that these bases were exported to Germany in considerable quantity. This tradition is worthily maintained by the Turnbridge works of the B.D.C., by Messrs. Hickson and Partners, of Castleford, who produce the xylidines in excellent quality, and by Messrs. Leitch, of Milnsbridge, who make chemically pure *o*-toluidine and who have even surpassed their pre-war reputation in the manufacture of *m*-phenylenediamine and 2:4-tolylenediamine.

Less advance had, however, been made prior to 1914 in the production of benzidine and other diamines leading to direct cotton azo-colours. This branch of intermediate production has been strengthened very considerably and the benzidine bases are now manufactured by the British Dyestuffs Corporation, by the Clayton Aniline Co., and by Messrs. Hickson and Partners.

Included within the wide category of azo-dyes are many valuable acid mordant colours. One of the fastest of these dyes is diamond black P V, introduced into the list of English dyes only since the war, and now manufactured by two firms.

Miscellaneous Intermediates and Dyes

There are still, however, a few intermediates which have not been produced on a works scale. One of these is resorcinol and another is the so-called naphthol A S (the anilide of β-hydroxynaphthoic acid). But since the raw materials, with one or two exceptions, are available from British sources, it may be anticipated that these and other missing intermediates will before long find their place in the list of British manufactures.

One of the foregoing exceptions is methyl alcohol, of which at present there is a great shortage, owing in part to its consumption as a beverage in America in place of the more wholesome ethyl alcohol. The home production of dimethylaniline, important alike in peace and war, has been hindered and rendered more costly by the dearth of wood spirit, and an adequate supply of this important chemical within the British Empire would be of the utmost value to chemical industry. Given a sufficient quantity of methyl alcohol, the dimethylaniline plant of the B.D.C., which was enlarged for military requirements during the war, is of sufficient capacity to cope fully with the demands of British colourmakers for this important intermediate. The production of other alkylated anilines involves the use of ethyl alcohol and the employment of the industrial quality of this spirit is hindered very considerably by the stringency of the existing Excise Regulations. Some relaxation of these Regulations so as to permit of a wider use of duty-free alcohol would be a valuable assistance to the dye industry as well as to other producers of organic chemicals.

Closely connected with alkylated anilines is the manufacture of malachite and brilliant greens and other more modern dyes of the triphenylmethane series. During the war period there was a big demand for triphenylmethane colours of the patent blue type which are produced in part from alkylanilines. The urgency of this demand from the dye users was so great that the B.D.C. erected in their Dalton works an entirely new plant at a cost of £80,000 for the manufacture of the patent blue series. In May, 1920, one of these colours was put on the market at 25s. per pound to meet the competition of the German product then selling at that price. Ten months later the Corporation introduced an improved brand of the colour somewhat superior to the German type and offered it at 13s. 6d. a pound. In the early part of the present year they were prepared to accept bulk orders for this colour at the very closely cut price of 8s. a pound. Their present reward for this highly successful enterprise is that they have now been met by applications for import licenses for the equivalent foreign colours at prices ranging from 4s. 8d. to 6s. 6d. per pound. Consequently the Corporation have been compelled to close down the plant and to cease manufacture. This was the only possible policy for the directors to adopt, having regard to the interests of their shareholders. Had they, however, carried on at a loss by reducing their selling price still further, say to 4s., it is fairly obvious that the English agents of German manufacturers would have filed license applications on behalf of their colour-using clients at still lower prices. That this experience is not limited to colours of a special group is shown by another example cited by the chairman of the Corporation. Owing to the efficient production of the necessary intermediates, the Corporation was able to produce a valuable direct cotton colour in great demand, at 12s. 3d. per pound, and for large quantities they are prepared to take the exceptionally low price of 4s. 3d., which is considerably under the cost of production. The Licensing Committee appointed under the Dyestuffs Act have received applications to import the German equivalents of this colour at 2s. 9d., and these examples of unfair competition could be multiplied.

The Licensing Committee is now the battleground of the user who desires to import a colour and the maker who objects to its importation on the ground that there is a British equivalent. Formerly applications to import were made on the score of quality, but now that the British-made dyes generally approximate to the Continental type in this respect the applications are increasingly put forward on price grounds. A year ago it was agreed to grant applications if the British prices were either more than three times the pre-war prices of the dyes in question, or higher than the current foreign price if the latter happened to be higher than the three-times factor. The makers agreed to this arrangement on the understanding that some financial assistance would be afforded by the Government, but as this anticipation has not been fulfilled, the expediency of retaining the three-times factor is now being questioned.

In this connexion it should be mentioned that, taken over a wide range of dyes, the average present British price is about two and a half times the average pre-war price, and even in the more limited range of anthraquinone dyes the present price is not more than 2·7 times the pre-war quotation. The reason for these comparatively low ratios is that many of the more easily manufactured dyes can be sold with profit at twice the pre-war price or even less. On the other hand, however, there are special dyes difficult to manufacture which could only be sold with profit on the basis of a five or six times factor.

Hence the three-times factor penalises the adventurous maker who endeavours to produce the more highly specialised dyes, inasmuch as he cannot afford to sell the product of the first trial batches at the three-times factor until he has made the economies arising from longer practical experience and from production to the full extent of his plant.

Due regard must be had, however, to the viewpoint of the British dye-users who claim that, by paying for dyes at three times the pre-war prices, they are bearing an undue share of the cost of establishing a dye-making industry in this country. They see their foreign competitors having access to dyes from German sources offered in neutral markets at prices against which no country with a stabilised currency can compete, and their business instinct revolts at the idea of being compelled to purchase in any but the cheapest markets.

So long as foreign dyers and printers are able to obtain their dyes at ridiculously low prices our dye consumers will clamour for a continual lowering of British prices until they reach the German level. It is, therefore, evident that this policy, if consistently pursued, involves the destruction of the new British dyestuffs industry. Possibly, however, those colour users who are alive to the risks involved in the recovery by the German Interessen Gemeinschaft of the monopoly in dyewares, will call a halt before this desperate position is reached. Recent events in the Ruhr have served to awaken a sense of this danger.

FUTURE PROSPECTS OF THE NEW INDUSTRY

The financial interests involved in the well-being of the newly-created dye industry are very considerable. The cost of land, buildings, plant and machinery involved in the development of the British Dyestuffs Corporation alone represents an expenditure of more than £7,000,000. Other firms have spent large sums in the erection of new works, and all these extensions were made at a time when the cost of building and plant was exceptionally high. In most instances the directors have written off large sums as an offset to the abnormal cost of construction and to the rapid depreciation of their chemical plant. But, even with this wise management, the difficulties of the infant industry are very considerable. One of the chief troubles arises from the present trade depression and the consequent diminution in the demand for dye-wares. There are too few orders to keep the plants running at full capacity, and, consequently, the cost of production tends to increase in spite of the economies effected as the result of greater technical experience.

Before new and important colours can be placed on the market many costly investigations have to be carried out. The research expenditure of the British Dyestuffs Corporation during the last four years has amounted to £400,000. Large and well-equipped laboratories have been established with research facilities comparable with those existing in the German colour works. A special feature of this installation is the provision of experimental plant on a semi-works scale. The research staff consists of upwards of thirty chemists of high scientific attainments. Similar research staffs are maintained by the other large dye-producers. This provision for original research has been justified by the rapid extension of the list of British-made colours which is still in progress, and by the introduction of entirely new dyes such as the ionamines of the Dyestuffs Corporation and the Caledon jade-green series of Scottish Dyes.

The continental makers are continuously engaged in improving the quality of their existing dyes and in introducing new colours, as, for example, the neolan series of mordant dyes by the Swiss makers. A defensive policy of research restricted to the imitation of foreign dyes would result in the British makers being always a little behind the latest improvements. It is, of course, essential that our colour producers should strive unceasingly to reduce the number of non-contentious dyes (dyes not made in Great Britain), but it is also desirable that they should seek for entirely new colouring matters, and in this way retain the initiative, which is as important in industrial competition as in military warfare.

The above-described activities in regard to dyes for textile requirements do not represent the total effort which is being put forth by the British colour makers. Attention is being paid to the production of dyes for non-textile purposes, such as the colouring of foodstuffs, varnishes, lacquers and polishes. This side of dye production is to be seen in the old-established works of Williams Bros, of Hounslow, a firm of classical reputation founded by Greville Williams, and the scene of the manufacture of an early monazo colour, chrysoidine, by the Swiss chemist O. N. Witt.

The preparation of pigment colours of brilliant tint and superior fastness was a speciality of the pre-war German dye factories. The intricacies of this manufacture have now been mastered. Lithol red of excellent quality is prepared by the B.D.C., and by Messrs. Oliver Wilkins and Co., of Derby.

Messrs. Leitch and Co., who have devoted special attention to the pigments of the Hansa-yellow series, now manufacture a full range of these colours. The requirements of the paint and colour trades are now almost completely met by the home production of pigments.

Regarded as a standard for the fixing of prices, the pre-war prices of German dyes are somewhat misleading, because for the bulk of their profits the German firms relied on specialities either in colours or in synthetic drugs, photographic chemicals and other high-grade products. The B.D.C. have extended in the direction of these remunerative specialities, and are producing photographic materials and medicinal products such as acriflavine, novocaine, and other drugs. The discovery of new side lines is of vital importance to the progress of the coal-tar products industries.

The most urgent requirement of the British colour-maker at the present time is a stabilisation of prices for a reasonable period. The unfair competition of German dye-makers depending on the devaluation of the mark as a medium of exchange should be met by strong Government action leading to concerted measures by the Allies against Germany. A firm insistence on the prompt payment of reparations would go a long way towards solving the price problem.

Meanwhile, and in spite of the adverse influences of trade depression, unfair foreign competition, excessive taxation and high cost of production, the new dye-making industry has been definitely established in this country. For the time being the German monopoly is broken, inasmuch as the quality of our home production is equal to that of the best foreign types, and our total output of colour is sufficient to satisfy more than 80 per cent. of the requirements of the colour users. During the dislocation of German dye-making produced by the occupation of the Ruhr this percentage of home production was considerably increased. At the outset of this crisis it was a fortunate circumstance for the consumer that the British dye-makers were in a position to meet his demands in view of the uncertainty of German supplies.

Besides furnishing arsenals of sufficient capacity to meet the varied and extensive needs of modern warfare, the British dyestuffs industry is the only scientific business in this country in which during peace time an adequate number of chemists can be trained in the technique of applied organic chemistry. In a national emergency these highly-skilled workers would be essential to the rapid and efficient production of munitions of war. Moreover, the dye-making industry acts as a feeder to other trades in fine chemicals, such as synthetic drugs, photographic chemicals, artificial resins, synthetic tanning materials, and many other scientific products. The failure of our synthetic-dye industry would mean the rapid disappearance of many allied branches of chemical trade. On the other hand, the industrial supremacy and national security of the British Empire are closely bound up with the well-being and progressive development of the newly-created industry in dyes and intermediates. It is in the public interest that the difficulties attending this recent development should be fully appreciated in order that the youthful industry may be nurtured and safeguarded until it attains to a healthy and vigorous maturity.

Edgbaston, Birmingham

ADVANCE PROOFS OF PAPERS

Authors of papers which are to be read before local sections or groups, may in some cases desire to have a few advance proofs for distribution among those likely to make useful contributions to the discussion. Any author who requires such advance proofs is requested to hand the manuscript of his paper to the Local Secretary so that it may reach the Editor at least *one month* before the date of the meeting at which it is to be read, in order to allow sufficient time for it to be considered by the Publications Committee and, if approved, set up in type.

THE ELECTRICAL STRUCTURE OF MATTER*

By Prof. SIR ERNEST RUTHERFORD, D.Sc., LL.D., F.R.S.

The discovery of X-rays by Röntgen was published to the world in 1895, whilst the discovery of the radioactivity of uranium by Becquerel was announced early in 1896. Even the most imaginative of our scientific men could never have dreamed at that time of the extension of our knowledge of the structure of matter that was to develop from these two fundamental discoveries, but in the records of the Liverpool meeting in 1896 we see the dawning recognition of the possible consequences of the discovery of X-rays, not only in their application to medicine and surgery, but as a new and powerful agent for attacking some of the fundamental problems of physics. In applied physics, too, this year marked the beginning of another advance. In the discussion of a paper which I had the honour to read, on a new magnetic detector of electrical waves, the late Sir W. Preece told the meeting of the successful transmission of signals for a few hundred yards by electric waves which had been made in England by a young Italian, G. Marconi. The first public demonstration of signalling for short distances by electric waves had been given by Sir Oliver Lodge at the Oxford Meeting of this Association in 1894.

It is of great interest to note that the benefits of this union of pure and applied research have not been one-sided. If the fundamental researches of the workers in pure science supply the foundations on which the applications are surely built, the successful practical application in turn quickens and extends the interest of the investigator in the fundamental problem, whilst the development of new methods and appliances for technical purposes often provides the investigator with means of attacking still more difficult questions. This important reaction between pure and applied science can be illustrated in many branches of knowledge, particularly in the industrial development of X-ray radiography for therapeutic and industrial purposes, where the development on a large scale of special X-ray tubes and improved methods of excitation has given the physicist much more efficient tools to carry out his researches on the nature of the rays themselves and on the structure of the atom. In this age no one can draw any sharp line of distinction between the importance of so-called pure and applied research. Both are equally essential to progress, and we cannot but recognise that without flourishing schools of research on fundamental matters in our universities and scientific institutions technical research must tend to wither.

---

* Presidential Address (abridged) delivered before the British Association for the Advancement of Science in Liverpool, on September 12.

It is my intention to refer very briefly to some of the main features of that great advance in knowledge of the nature of electricity and matter which is one of the salient features of the interval since the last meeting of this Association in Liverpool. In order to view the extensive territory conquered by science in this interval, it is desirable to give a brief summary of the state of knowledge of the constitution of matter at the beginning of this epoch. Ever since its announcement by Dalton, the atomic theory has steadily gained ground, and formed the philosophic basis for the explanation of the facts of chemical combination. In the early stages of its application to physics and chemistry it was unnecessary to have any detailed knowledge of the dimensions or structure of the atom. It was only necessary to assume that the atoms acted as individual units, and to know the relative masses of the atoms of the different elements. In the next stage, for example, in the kinetic theory of gases, it was possible to explain the main properties of gases by supposing that the atoms of the gas acted as minute perfectly elastic spheres. During this period, by the application of a variety of methods, many of which were due to Lord Kelvin, rough estimates had been obtained of the absolute dimensions and mass of the atoms. These brought out the minute size and mass of the atom and the enormous number of atoms necessary to produce a detectable effect in any kind of measurement.

Whilst the vaguest ideas were held as to the possible structure of atoms, there was a general belief among the more philosophically minded that the atoms of the elements could not be regarded as simple unconnected units. The periodic variations of the properties of the elements brought out by Mendeléef were only explicable if atoms were similar structures in some way constructed of similar material. We shall see that the problem of the constitution of atoms is intimately connected with our conception of the nature of electricity. At the same time the idea was generally gaining ground that an explanation of the results of Faraday's experiments on electrolysis was only possible on the assumption that electricity, like matter, was atomic in nature. The name "electron" had even been given to this fundamental unit by Johnstone Stoney, and its magnitude roughly estimated, but the full recognition of the significance and importance of this conception belongs to the new epoch.

To clarify these somewhat vague ideas, the proof in 1897 of the independent existence of the electron as a mobile electrified unit, of mass minute compared with that of the lightest atom, was of extraordinary importance. It was soon seen that the electron must be of a constituent of all the atoms of matter, and that optical spectra had their origin in their vibrations. The discovery of the electron and the proof of its liberation by a variety of methods from all the atoms of matter was of the utmost significance, for it strengthened the view that the electron was probably the common unit in the structure of atoms which the periodic variation of the chemical properties had indicated. In the early development of this subject science owes much to the work of Sir J. J. Thomson, both for the boldness of his ideas and for his ingenuity in developing methods for estimating the number of electrons in the atom, and of probing its structure. He early took the view that the atom must be an electrical structure, held together by electrical forces, and showed in a general way lines of possible explanation of the variation of physical and chemical properties of the elements, exemplified in the periodic law.

In the meantime our whole conception of the atom and of the magnitude of the forces which held it together were revolutionised by the study of radioactivity. It was soon shown that the atoms of radioactive matter were undergoing spontaneous transformation, and that the characteristic radiations emitted, viz., the α, β, and γ rays, were an accompaniment and consequence of these atomic explosions. The wonderful succession of changes that occur in uranium, more than thirty in number, was soon disclosed and simply interpreted on the transformation theory. The radioactive elements provide us for the first time with a glimpse into Nature's laboratory, and allow us to watch and study, but not control, the changes that have their origin in the heart of the radioactive atoms. These atomic explosions involve energies which are gigantic compared with those involved in any ordinary physical or chemical process. In the majority of cases an α particle is expelled at high speed, but in others a swift electron is ejected often accompanied by a γ ray, which is a very penetrating X-ray of high frequency. The proof that the α particle is a charged helium atom for the first time disclosed the importance of helium as one of the units in the structure of the radioactive atoms, and probably also in that of the atoms of most of the ordinary elements. Not only then have the radioactive elements had the greatest direct influence on natural philosophy, but in subsidiary ways they have provided us with experimental methods of almost equal importance. The use of α particles as projectiles with which to explore the interior of the atom has definitely exhibited its nuclear structure, has led to artificial disintegration of certain light atoms, and promises to yield more information yet as to the actual structure of the nucleus itself.

The influence of radioactivity has also extended to yet another field of study of fascinating interest. We have seen that the first rough estimates of the size and mass of the atom gave little hope that we could detect the effect of a single atom. The discovery that the radioactive bodies expel actual charged atoms of helium with enormous energy altered this aspect of the problem. The energy associated with a single α particle is so great that it can readily be detected by a variety of methods. Each α particle, as Sir Wm. Crookes first showed, produces a flash of light easily visible in a dark room when it falls on a screen coated with crystals of zinc sulphide. This scintillation method of counting individual particles has proved invaluable in many researches, for it gives us a method of unequalled delicacy for studying the effects of single atoms. The α particle can also be detected electrically or photographically, but the most powerful and beautiful of all methods is that perfected by Mr. C. T. R. Wilson for observing the track through a gas not only of an α particle but of any type of penetrating radiation which produces ions or electrified particles along its path. The method is comparatively simple, depending on the fact, first discovered by him, that if a gas saturated with moisture is suddenly cooled each of the ions produced by the radiation becomes the nucleus of a visible drop of water. The water-drops along the track of the α particle are clearly visible to the eye, and can be recorded photographically.

In the meantime a number of new methods had been devised to fix with some accuracy the mass of the individual atom and the number in any given quantity of matter. The concordant results obtained by widely different physical principles gave great confidence in the correctness of the atomic idea of matter. The method found capable of most accuracy depends on the definite proof of the atomic nature of electricity and the exact valuation of this fundamental unit of charge. We have seen that it was early surmised that electricity was atomic in nature. This view was confirmed and extended by a study of the charges carried by electrons, α particles, and the ions produced in gases by X-rays and the rays from radioactive matter. It was first shown by Townsend that the positive or negative charge carried by an ion in gases was invariably equal to the charge carried by the hydrogen ion in the electrolysis of water, which we have seen was assumed, and assumed correctly, by Johnstone Stoney to be the fundamental unit of charge. Various methods were devised to measure the magnitude of this fundamental unit; the best known and most accurate is Millikan's, which depends on comparing the pull of an electric field on a charged droplet of oil or mercury with the weight of the drop. His experiments gave a most convincing proof of the correctness of the electronic theory, and gave a measure of this unit, the most fundamental of all physical units, with an accuracy of about one in a thousand. Knowing this value, we can by the aid of electrochemical data easily deduce the mass of the individual atoms and the number of molecules in a cubic centimetre of any gas with an accuracy of possibly one in a thousand, but certainly better than one in a hundred.

The idea of the atomic nature of electricity is very closely connected with the attack on the problem of the structure of the atom. If the atom is an electrical structure it can only contain an integral number of charged units, and, since it is ordinarily neutral, the number of units of positive charge must equal the number of negative. One of the main difficulties in this problem has been the uncertainty as to the relative part played by positive and negative electricity in the structure of the atom. We know that the electron has a negative charge of one fundamental unit, whilst the charged hydrogen atom, whether in electrolysis or in the electric discharge, has a charge of one positive unit. But the mass of the electron is only 1/1840 of the mass of the hydrogen atom, and though an extensive search has been made, not the slightest evidence has been found of the existence of a positive electron of small mass like the negative. In no case has a positive charge been found associated with a mass less than that of the charged atom of hydrogen. This difference between positive and negative electricity is at first sight very surprising, but the deeper we pursue our inquiries the more this fundamental difference between the units of positive and negative electricity is emphasised. In fact, as we shall see later, the atoms are quite unsymmetrical structures with regard to the positive and negative units contained in them, and indeed it seems certain that if there were not this difference in mass between the two units, matter, as we know it, could not exist.

It is natural to inquire what explanation can be given of this striking difference in mass of the two units. I think all scientific men are convinced that the small mass of the negative electron is to be entirely associated with the energy of its electrical structure, so that the electron may be regarded as a disembodied atom of negative electricity. We know that an electron in motion, in addition to possessing an electric field, also generates a magnetic field around it, and energy in the electromagnetic form is stored in the medium and moves with it. This gives the electron an apparent or electrical mass, which, while nearly constant for slow speeds, increases rapidly as its velocity approaches that of light. This increase of mass is in good accord with calculation, whether based on the ordinary electrical theory or on the theory of relativity. Now we know that the hydrogen atom is the lightest of all atoms, and is presumably the simplest in structure, and that the charged hydrogen atom, which we shall see is to be regarded as the hydrogen nucleus, carries a unit positive charge. It is thus natural to suppose that the hydrogen nucleus is the atom of positive electricity, or positive electron, analogous to the negative electron, but differing from it in mass. Electrical theory shows that the mass of a given charge of electricity increases with the concentration, and the greater mass of the hydrogen nucleus would be accounted for if its size were much smaller than that of the electron. Such a conclusion is supported by evidence obtained from the study of the close collisions of α particles with hydrogen nuclei. It is found that the hydrogen nucleus must be of minute size, of radius less than the electron, which is usually supposed to be about 10^{-13} cm.; also the experimental evidence is not inconsistent with the view that the hydrogen nucleus may actually be much smaller than the electron.

There is the strongest evidence that the atoms of matter are built up of these two electrical units, viz., the electron and the hydrogen nucleus or proton, as it is usually called when it forms part of the structure of any atom. It is probable that these two are the fundamental and indivisible units which build up our universe, but we may reserve in our mind the possibility that further inquiry may some day show that these units are complex, and divisible into even more fundamental entities. On the views we have outlined, the mass of the atom is the sum of the electrical masses of the individual charged units composing its structure, and there is no need to assume that any other kind of mass exists. At the same time, it is to be borne in mind that the actual mass of an atom may be somewhat less than the sum of the masses of component positive and negative electrons when in the free state. On account of the very close proximity of the charged units in the nucleus of an atom, and the consequent disturbance of the electric and magnetic field surrounding them, such a decrease of mass is to be anticipated on general theoretical grounds.

We must now look back again to the earlier stages of the present epoch in order to trace the development of our ideas on the detailed structure of the atom. That electrons as such were important constituents was clear by 1900, but little real progress followed until the part played by the positive charges was made clear. New light was thrown on this subject by examining the deviation of α particles when they passed through the atoms of matter. It was found that occasionally a swift α particle was deflected from its rectilinear path through more than a right angle by an encounter with a single atom. In such a collision the laws of dynamics ordinarily apply, and the relation between the velocities of the colliding atoms before and after collision are exactly the same as if the two colliding particles are regarded as perfectly elastic spheres of minute dimensions. It must, however, be borne in mind that in these atomic collisions there is no question of mechanical impacts such as we observe with ordinary matter. The reaction between the two particles occurs through the intermediary of the powerful electric fields that surround them. Beautiful photographs illustrating the accuracy of these laws of collision between an α particle and an atom have been obtained by Messrs. Wilson, Blackett, and others, while Mr. Wilson has recently obtained many striking illustrations of collisions between two electrons. Remembering the great kinetic energy of the α particle, its deflection through a large angle in a single atomic encounter shows clearly that very intense deflecting forces exist inside the atom. It seemed clear that electric fields of the required magnitude could be obtained only if the main charge of the atom were concentrated in a minute nucleus. From this arose the conception of the nuclear atom, now so well known, in which the heart of the atom is supposed to consist of a minute but massive nucleus, carrying a positive charge of electricity, and surrounded at a distance by the requisite number of electrons to form a neutral atom.

A detailed study of the scattering of α particles at different angles, by Geiger and Marsden, showed that the results were in close accord with this theory, and that the intense electric forces near the nucleus varied according to the ordinary inverse square law. In addition, the experiments allowed us to fix an upper limit for the dimensions of the nucleus. For a heavy atom like that of gold the radius of the nucleus, if supposed to be spherical, was less than one-thousandth of the radius of the complete atom surrounded by its electrons, and certainly less than 4×10^{-12} cm. All the atoms were found to show this nuclear structure, and an approximate estimate was made of the nuclear charge of different atoms. This type of nuclear atom, based on direct experimental evidence, possesses some very simple properties. It is obvious that the number of units of resultant positive charge in the nucleus fixes the number of the outer planetary electrons in the neutral atom. In addition, since these outer electrons are in some way held in equilibrium by the attractive forces from the nucleus, and, since we are confident from general physical and chemical evidence that all atoms of any one element are identical in their external structure, it is clear that their arrangement and motion must be governed entirely by the magnitude of the nuclear charge. Since the ordinary chemical and physical properties are to be ascribed mainly to the configuration and motion of the outer electrons, it follows that the properties of an atom are defined by a whole number representing its nuclear charge. It thus becomes of great importance to determine the value of this nuclear charge for the atoms of all the elements.

Data obtained from the scattering of α particles, and also from the scattering of X-rays by light elements, indicated that the nuclear charge of an element was numerically equal to about half the atomic weight in terms of hydrogen. It was fairly clear from general evidence that the hydrogen nucleus had a charge one, and the helium nucleus (the α particle) a charge two. At this stage another discovery of great importance provided a powerful method of attack on this problem.

The investigation by Laue on the diffraction of X-rays by crystals had shown definitely that X-rays were electromagnetic waves of much shorter wave-length than light, and the experiments of Sir William Bragg and W. L. Bragg had provided simple methods for studying the spectra of a beam of X-rays. It was found that the spectrum in general shows a continuous background on which is superimposed a spectrum of bright lines. At this stage H. G. J. Moseley began a research with the intention of deciding whether the properties of an element depended on its nuclear charge rather than on its atomic weight as ordinarily supposed. For this purpose the X-ray spectra emitted by a number of elements were examined and found to be all similar in type. The frequency of a given line was found to vary very nearly as the square of a whole number which varied by unity in passing from one element to the next. Moseley identified this whole number with the atomic or ordinal number of the elements when arranged in increasing order of atomic weight, allowance being made for the known anomalies in the periodic table and for certain gaps corresponding to possible but missing elements. He concluded that the atomic number of an element was a measure of its nuclear charge, and the correctness of this deduction has been recently verified by Chadwick by direct experiments on the scattering of α particles. Moseley's discovery is of fundamental importance, for it not only fixes the number of electrons in all the atoms, but shows conclusively that the properties of an atom, as had been surmised, are determined not by its atomic weight but by its nuclear charge. A relation of unexpected simplicity is thus found to hold between the elements. No one could have anticipated that with few exceptions all atomic numbers between hydrogen 1, and uranium 92, would correspond to known elements. The great power of Moseley's law in fixing the atomic number of an element is well illustrated by the recent discovery by Coster and Hevesy in Copenhagen of the missing element of atomic number 72, which they have named 'hafnium.'

Once the salient features of the structure of atoms have been fixed and the number of electrons known, the further study of the structure of the atom falls naturally into two great divisions: one, the arrangement of the outer electrons which controls the main physical and chemical properties of an element, and the other the structure of the nucleus on which the mass and radioactivity of the atom depends. On the nuclear theory the hydrogen atom is of extreme simplicity, consisting of a singly-charged positive nucleus with only one attendant electron. The position and motions of the single electron must account for the complicated optical spectrum, and whatever physical and chemical properties are to be attributed to the hydrogen atom. The first definite attack on the problem of the electronic structure of the atom was made by Niels Bohr. He saw clearly that, if this simple constitution was assumed, it is impossible to account for the spectrum of hydrogen on the classical electrical theories, but that a radical departure from existing views was necessary. For this purpose he applied to the atom the essential ideas of the Quantum Theory which had been developed by Planck for other purposes, and had been found of great service in explaining many fundamental difficulties in other branches of science. On Planck's theory radiation is emitted in definite units or quanta, in which the energy E of a radiation is equal to $h\nu$ where ν is the frequency of the radiation measured by the ordinary methods and h a universal constant. This quantum of radiation is not a definite fixed unit like the atom of electricity, for its magnitude depends on the frequency of the radiation. For example, the energy of a quantum is small for visible light, but becomes large for radiation of high frequency corresponding to the X-rays or the γ rays from radium.

In applying the quantum theory to the structure of the hydrogen atom Bohr supposed that the single electron could move in a number of stable orbits, controlled by the attractive force of the nucleus, without losing energy by radiation. The position and character of these orbits were defined by certain quantum relations depending on one or more whole numbers. It was assumed that radiation was only emitted when the electron for some reason was transferred from one stable orbit to another of lower energy. In such a case it was supposed that a homogeneous radiation was emitted of frequency ν determined by the quantum relation $E=h\nu$ where E was the difference of the energy of the electron in the two orbits. Some of these possible orbits are circular, others elliptical, with the nucleus as a focus, whilst if the change of mass of the electron with velocity is taken into account, the orbits, as Sommerfeld showed, depend on two quantum numbers, and are not closed, but consist of a nearly elliptical orbit slowly rotating round the nucleus. In this way it is possible not only to account for the series relations between the bright lines of the hydrogen spectrum, but also to explain the fine structure of the lines and the very complicated changes observed when the radiating atoms are exposed in a strong magnetic or electric field. Under ordinary conditions the electron in the hydrogen atom rotates in a circular orbit close to the nucleus, but if the atoms are excited by an electric discharge or other suitable method, the electron may be displaced and occupy any one of the stable positions specified by the theory. In a radiating gas giving the complete hydrogen spectrum there will be present many different kinds of hydrogen atoms, in each of which the electron describes one of the possible orbits specified by the theory. On this view it is seen that the variety of modes of vibration of the hydrogen atom is ascribed, not to complexity of the structure of the atom, but to the variety of stable orbits which an electron may occupy relative to the nucleus. This novel theory of the origin of spectra has been developed so as to apply not only to hydrogen but to all the elements, and has been instrumental in throwing a flood of light on the relations and origin of their spectra, both X-ray and optical. The information thus gained has been applied by Bohr to determine the distribution of the electrons round the nucleus of any atom. The problem is obviously much less complicated for hydrogen than for a heavy atom, where each of the large number of electrons present acts on the other, and where the orbits described are much more intricate than the orbit of the single electron in hydrogen. Notwithstanding the great difficulties of such a complicated system of electrons in motion, it has been possible to fix the quantum numbers that characterise the motion of each electron, and to form at any rate a rough idea of the character of the orbit.

These planetary electrons divide themselves up into groups, according as their orbits are characterised by one or more equal quantum numbers. Without going into detail a few examples may be given to illustrate the conclusions which have been reached. As we have seen, the first element hydrogen has a nuclear charge of 1 and 1 electron ; the second, helium, has a charge 2 and 2 electrons, moving in coupled orbits on the detailed nature of which there is still some uncertainty. These two electrons form a definite group, known as the K group, which is common to all the elements except hydrogen. For increasing nuclear charge the K group of electrons retain their characteristics, but move with increasing speed, and approach closer to the nucleus. As we pass from helium of atomic number 2 to neon, number 10, a new group of electrons is added consisting of two sub-groups, each of four electrons, together called the L group. This L group appears in all atoms of higher atomic number, and, as in the case of the K group, the speed of motion of the electrons increases, and the size of their orbits diminishes with the atomic number. When once the L group has been completed a new and still more complicated M group of electrons begins forming outside it, and a similar process goes on until uranium, which has the highest atomic number, is reached.

It may be of interest to try to visualise the conception of the atom we have so far reached by taking for illustration the heaviest atom, uranium. At the centre of the atom is a minute nucleus surrounded by a swirling group of 92 electrons, all in motion in definite orbits, and occupying but by no means filling a volume very large compared with that of the nucleus. Some of the electrons describe nearly circular orbits round the nucleus ; others, orbits of a more elliptical shape whose axes rotate rapidly round the nucleus. The motion of the electrons in the different groups is not necessarily confined to a definite region of the atom, but the electrons of one group may penetrate deeply into the region mainly occupied by another group, thus giving a type of inter-connexion or coupling between the various groups. The maximum speed of any electron depends on the closeness of the approach to the nucleus, but the outermost electron will have a minimum speed of more than 1000 kilometres per second, whilst the innermost K electrons have an average speed of more than 150,000 kilometres per second, or half the speed of light. When we visualise the extraordinary complexity of the electronic system we may be surprised that it has been possible to find any order in the apparent medley of motions.

It is possibly too soon to express a final opinion on the accuracy of this theory which defines the outer structure of the atom, but there can be no doubt that it constitutes a great advance. Not only does it offer a general explanation of the optical and X-ray spectra of the atom, but it accounts in detail for many of the most characteristic features of the periodic law of Mendeléef. It gives us for the first time a clear idea of the reason for the appearance in the family of elements of groups of consecutive elements with similar chemical properties, such as the groups analogous to the iron group and the unique group of rare earths. The theory of Bohr, like all living theories, has not only correlated a multitude of isolated facts known about the atom, but has shown its power to predict new relations which can be verified by experiment. For example, the theory predicted the relations which must subsist between the Rydberg constants of the arc and spark spectra, and generally between all the successive optical spectra of an element, a prediction so strikingly confirmed by Paschen's work on the spectrum of doubly ionised aluminium and Fowler's work on the spectrum of trebly ionised silicon. Finally, it predicted with such great confidence the chemical properties of the missing element, number 72, that it gave the necessary incentive for its recent discovery.

We have not so far referred to the very difficult question of the explanation on this theory of the chemical combination of atoms. In fact, as yet the theory has hardly concerned itself with molecular structure. On the chemical side, however, certain advances have already been made, notably by G. N. Lewis, Kossel, and Langmuir, in the interpretation of the chemical evidence by the idea of shared electrons, which play a part in the electronic structure of two combined atoms. There can be little doubt that the next decade will see an intensified attack by physicists and chemists on this very important but undoubtedly very complicated question.

We must now turn our attention to that new and comparatively unexplored territory, the nucleus of the atom. In a discussion on the structure of the atom ten years ago, in answer to a question on the structure of the nucleus, I was rash enough to say that it was a problem that might well be left to the next generation, for at that time there seemed to be few obvious methods of attack to throw light on its constitution. Whilst much more progress has been made than appeared possible at that time, the problem of the structure of the nucleus is inherently more difficult than the allied problem already considered of the structure of the outer atom, where we have a wealth of information obtained from the study of light and X-ray spectra and from the chemical properties to test the accuracy of our theories.

In the case of the nucleus, we know its resultant charge, fixed by Moseley's law, and its mass, which is very nearly equal to the mass of the whole atom, since the mass of the planetary electrons is relatively very small and may for most purposes be neglected. We know that the nucleus is of size minute compared with that of the whole atom, and can with some confidence set a maximum limit to its size. The study of radioactive bodies has provided us with very valuable information on the structure of the nucleus, for we know that the α and β particles must be expelled from it, and there is strong evidence that the very penetrating γ rays represent modes of vibration of the electrons contained in its structure. In the long series of transformations which occur in the uranium atom, eight α particles are emitted and six electrons, and it seems clear that the nucleus of a heavy atom is built up, in part at least, of helium nuclei and electrons. It is natural to suppose that many of the ordinary stable atoms are constituted in a similar way. It is a matter of remark that no indication has been obtained that the lightest nucleus, viz., that of hydrogen, is liberated in these transformations, where the processes occurring are of so fundamental a character. At the same time, it is evident that the hydrogen nucleus must be a unit in the structure of some atoms, and this has been confirmed by direct experiment. Dr. Chadwick and I have observed that swift hydrogen nuclei are released from the elements boron, nitrogen, fluorine, sodium, aluminium, and phosphorus when they are bombarded by swift α particles, and there is little room for doubt that these hydrogen nuclei form an essential part of the nuclear structure. The speed of ejection of these nuclei depends on the velocity of the α particle and on the element bombarded. It is of interest to note that the hydrogen nuclei are liberated in all directions, but the speed in the backward direction is always somewhat less than in the direction of the α particle. Such a result receives a simple explanation if we suppose that the hydrogen nuclei are not built into the main nucleus but exist as satellites probably in motion round a central core. There can be no doubt that bombardment by α particles has effected a veritable disintegration of the nuclei of this group of elements. It is significant that the liberation of hydrogen nuclei only occurs in elements of odd atomic number, viz., 5, 7, 9, 11, 13, 15, the elements of even number appearing quite unaffected. For a collision of an α particle to be effective, it must either pass close to the nucleus or actually penetrate its structure. The chance of this is excessively small on account of the minute size of the nucleus. For example, although each individual α particle will pass through the outer structure of more than 100,000 atoms of aluminium in its path, it is only about one α particle in a million that gets close enough to the nucleus to effect the liberation of its hydrogen satellite.

This artificial disintegration of elements by α particles takes place only on a minute scale, and its observation has only been possible by the counting of individual swift hydrogen nuclei by the scintillations they produce in zinc sulphide.

These experiments suggest that the hydrogen nucleus or proton must be one of the fundamental units which build up a nucleus, and it seems highly probable that the helium nucleus is a secondary building unit composed of the very close union of four protons and two electrons. The view that the nuclei of all atoms are ultimately built up of protons of mass nearly one and of electrons has been strongly supported and extended by the study of isotopes. It was early observed that some of the radioactive elements which showed distinct radioactive properties were chemically so alike that it was impossible to effect their separation when mixed together. Similar elements of this kind were called " isotopes " by Soddy, since they appeared to occupy the same place in the periodic table. For example, a number of radioactive elements in the uranium and thorium series have been found to have physical and chemical properties identical with those of ordinary lead, but yet to have atomic weights differing from ordinary lead, and also distinctive radioactive properties. The nuclear theory of the atom offers at once a simple interpretation of the relation between isotopic elements. Since the chemical properties of an element are controlled by its nuclear charge and little influenced by its mass, isotopes must correspond to atoms with the same nuclear charge but of different nuclear mass. Such a view also offers a simple explanation why the radioactive isotopes show different radioactive properties, for it is to be anticipated that the stability of a nucleus will be much influenced by its mass and arrangement.

Our knowledge of isotopes has been widely extended in the last few years by Aston, who has devised an accurate direct method for showing the presence of isotopes in the ordinary elements. He has found that some of the elements are " pure "—*i.e.*, consist of atoms of identical mass—while others contain a mixture of two or more isotopes. In the case of the isotopic elements, the atomic mass, as ordinarily measured by the chemist, is a mean value depending on the atomic masses of the individual isotopes and their relative abundance. These investigations have not only shown clearly that the number of distinct species of atoms is much greater than was supposed, but have brought out a relation between the elements of great interest and importance. The atomic masses of the isotopes of most of the elements examined have been found, to an accuracy of about one in a thousand, to be whole numbers in terms of oxygen, 16. This indicates that the nuclei are ultimately built up of protons of mass very nearly one and of electrons. It is natural to suppose that this building unit is the hydrogen nucleus, but that its average mass in the complex nucleus is somewhat less than its mass in the free state owing to the close packing of the charged units in the nuclear structure. We have already seen that the helium nucleus of mass 4 is probably a secondary unit of great importance in the building up of many atoms, and it may be that other simple combinations of protons and electrons of mass 2 and 3 occur in the nucleus, but these have not been observed in the free state.

Whilst the masses of the majority of the isotopes are nearly whole numbers, certain cases have been observed by Aston where this rule is slightly departed from. Such variations in mass may ultimately prove of great importance in throwing light on the arrangement and closeness of packing of the protons and electrons, and for this reason it is to be hoped that it may soon prove possible to compare atomic masses of the elements with much greater precision even than at present.

Before leaving this subject it is desirable to say a few words on the important question of the energy relations involved in the formation and disintegration of atomic nuclei, first opened up by the study of radioactivity. For example, it is well known that the total evolution of energy during the complete disintegration of one gramme of radium is many millions of times greater than in the complete combustion of an equal weight of coal. It is known that this energy is initially mostly emitted in the kinetic form of swift α and β particles, and the energy of motion of these bodies is ultimately converted into heat when they are stopped by matter. Since it is believed that the radioactive elements were analogous in structure to the ordinary inactive elements, the idea naturally arose that the atoms of all the elements contained a similar concentration of energy, which would be available for use if only some simple method could be discovered of promoting and controlling their disintegration. This possibility of obtaining new and cheap sources of energy for practical purposes was naturally an alluring prospect to the lay and scientific man alike. It is quite true that, if we were able to hasten the radioactive processes in uranium and thorium so that the whole cycle of their disintegration could be confined to a few days instead of being spread over thousands of millions of years, these elements would provide very convenient sources of energy on a sufficient scale to be of considerable practical importance. Unfortunately, although many experiments have been tried, there is no evidence that the rate of disintegration of these elements can be altered in the slightest degree by the most powerful laboratory agencies.

It may be urged that the artificial disintegration of certain elements by bombardment with swift α particles gives definite evidence of a store of energy in some of the ordinary elements, for it is known that a few of the hydrogen nuclei, released from aluminium for example, are expelled with such swiftness that the particle has a greater individual energy than the α particle which causes their liberation. Unfortunately, it is very difficult to give a definite answer on this point until we know more of the details of this disintegration.

On the other hand, another method of attack on this question has become important during the last few years, based on the comparison of the relative masses of the elements. This new point of view can best be illustrated by a comparison of the atomic masses of hydrogen and helium. As we have seen, it seems very probable that helium is not an ultimate unit in the structure of nuclei, but is a very close combination of four hydrogen nuclei and two electrons. The mass of the helium nucleus, 4·00 in terms of $O=16$, is considerably less than the mass 4·03 of four hydrogen nuclei. On modern views there is believed to be a very close connexion between mass and energy, and this loss in mass in the synthesis of the helium nucleus from hydrogen nuclei indicates that a large amount of energy in the form of radiation has been released in the building of the helium nucleus from its components. It is easy to calculate from this loss of mass that the energy set free in forming one gramme of helium is large even compared with that liberated in the total disintegration of one gramme of radium. For example, calculation shows that the energy released in the formation of one pound of helium gas is equivalent to the energy emitted in the complete combustion of about eight thousand tons of pure carbon. It has been suggested by Eddington and Perrin that it is mainly to this source of energy that we must look to maintain the heat emission of the sun and hot stars over long periods of time. Calculations of the loss of heat from the sun show that this synthesis of helium need only take place slowly in order to maintain the present rate of radiation for periods of the order of one thousand million years. It must be acknowledged that these arguments are somewhat speculative in character, for no certain experimental evidence has yet been obtained that helium can be formed from hydrogen.

The evidence of the slow rate of stellar evolution, however, certainly indicates that the synthesis of helium, and perhaps other elements of higher atomic weight, may take place slowly in the interior of hot stars. Whilst in the electric discharge through hydrogen at low pressure we can easily reproduce the conditions of the interior of the hottest star as far as regards the energy of motion of the electrons and hydrogen nuclei, we cannot hope to reproduce that enormous density of radiation which must exist in the interior of a giant star. For this and other reasons it may be very difficult, or even impossible, to produce helium from hydrogen under laboratory conditions.

If this view of the great heat emission in the formation of helium be correct, it is clear that the helium nucleus is the most stable of all nuclei, for an amount of energy corresponding to three or four α particles would be required to disrupt it into its components. In addition, since the mass of the proton in nuclei is nearly 1·000 instead of its mass 1·0072 in the free state, it follows that much more energy must be put into the atom than will be liberated by its disintegration into its ultimate units. At the same time, if we consider an atom of oxygen, which may be supposed to be built up of four helium nuclei as secondary units, the change of mass, if any, in its synthesis from already formed helium nuclei is so small that we cannot yet be certain whether there will be a gain or loss of energy by its disintegration into helium nuclei, but in any case we are certain that the magnitude of the energy will be much less than for the synthesis of helium from hydrogen. Our information on this subject of energy changes in the formation or disintegration of atoms in general is as yet too uncertain and speculative to give any decided opinion on future possibilities in this direction, but I have endeavoured to outline some of the main arguments which should be taken into account.

In watching the rapidity of this tide of advance in physics I have become more and more impressed by the power of the scientific method of extending our knowledge of Nature. Experiment, directed by the disciplined imagination either of an individual, or still better, of a group of individuals of varied mental outlook, is able to achieve results which far transcend the imagination alone of the greatest natural philosopher. Experiment without imagination, or imagination without recourse to experiment, can accomplish little, but, for effective progress, a happy blend of these two powers is necessary. The unknown appears as a dense mist before the eyes of men. In penetrating this obscurity we cannot invoke the aid of supermen, but must depend on the combined efforts of a number of adequately trained ordinary men of scientific imagination. Each in his own special field of inquiry is enabled by the scientific method to penetrate a short distance, and his work reacts upon and influences the whole body of other workers. From time to time there arises an illuminating conception, based on accumulated knowledge, which lights up a large region and shows the connexion between these individual efforts, so that a general advance follows. The attack begins anew on a wider front, and often with improved technical weapons. The conception which led to this advance often appears simple and obvious when once it has been put forward. This is a common experience, and the scientific man often feels a sense of disappointment that he himself had not foreseen a development which ultimately seems so clear and inevitable.

It is clear that the splendid period of scientific activity which we have reviewed to-night owes much of its success and intellectual appeal to the labours of those great men in the past, who wisely laid the sure foundations on which the scientific worker builds to-day, or to quote from the words inscribed in the dome of the National Gallery: "The works of those who have stood the test of ages have a claim to that respect and veneration to which no modern can pretend."

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

A VISIT TO THE ENGINEERING EXHIBITION

By Prof. J. W. HINCHLEY, A.R.S.M., Wh.Sc., M.I.Chem.E.

The Shipping, Engineering and Machinery Exhibition at Olympia, London, which opened on August 31 and will close on September 22, should be visited by all who are interested in the Chemical Industry, for it comes at an opportune time and is full of exhibits of great value. Although trade is bad, we can console ourselves with the knowledge that our credit is good, through the national finances being in good order, and that it ought to be possible to build up again our industrial machine while our competitors are still struggling with unrest. Exhibitions of this kind help towards that end, and this one in particular seems destined to do so.

The number of exhibits which are of direct value to the chemical engineer is very great; several visits will not exhaust the list of possible discoveries. Unfortunately, *discovery* is necessary for the stand system, in which each exhibitor raises barricades against his neighbours, which defeats the real object of the exhibition to a great extent.

An interesting catalogue is issued, but, as is often the case, some of the most interesting exhibits are not mentioned. The classified index, however, is most useful, but could be extended with great advantage.

.Steam power plants and their accessories are shown by the leading firms. The dissected full size chain-grate stoker of Messrs. Babcock & Wilcox, Ltd., and the economiser, with its scrapers in motion, of Messrs. E. Green & Son, Ltd., call for special comment. The model boilers at Messrs. John Thompson's stand give the best practice in Lancashire and similar boilers, and a small vertical boiler shown by Messrs. Robey & Co., Ltd., may be said to be the "latest" in vertical boilers. This boiler is provided with water tubes arranged to give better water circulation than is usual in such boilers.

Messrs. Spencer-Bonecourt, Ltd., show one of their small gas-fired boilers in operation, supplying steam to adjacent stands. The efficiency of the gas governor on this boiler is demonstrated very effectively.

Electric and other motors are shown by many firms; one of these, the "Willing Worker," a small portable or fixed paraffin engine (3 h.p.) exhibited by Messrs. Drummond Brothers, Ltd., together with its associated tools, has great interest for the manufacturer in out-of-the-way places. The associated tools are a specially designed drag saw and a force pump, which form "willing worker units" of great utility.

Every factory manager is aware of the importance of sound design, quality and workmanship in the details of his plant, and of the balance-sheet value of those accessories which, while being effective, need no attention for replacement, repair or breakdown. The exhibition contains a large number of examples of accessories which will attract the practical manager. The B. & S. Packless Valve shown by Messrs. Butler & Son, Ltd., avoids the use of packing, the usual steam leakage and other consequent troubles. The writer has some experience of this valve, the workmanship of which commands admiration. The Reducing Valve of Messrs. Clark & Son, Ltd., is another example of an excellent accessory. It has neither diaphragm nor springs and can be readily adjusted to the required pressure conditions. The same firm exhibits a steam heating system for ships in which only one pipe is used for the connexion with the radiators. The control fitting on each radiator determines circulation by an application of the "Venturi" principle of a converging and diverging nozzle. There seems to be no reason why the system should not be applied to factory and other buildings.

The full-bore valves shown by Messrs. Robey & Co., Ltd., should be carefully inspected. A clear way passage is formed right through the casing while the valve and its seat are sheltered from the flowing fluid. Another valve exhibited by the same firm is a gate valve provided on its back with three stainless-steel pins, which may be screwed on its face and used as a guide for grinding the valve and its seat "true" after removal from the casing. Another gate valve, which has been designed for viscous fluids which tend to cement the parts together, has little more than line contact on the valve face, and the first effect of opening the valve is to "pull" the face of the valve from the seating.

The "Menno" Automatic Compressed Air Grease Cup is another simple device which will recommend itself. The feed of grease is determined by the air trapped and compressed in the upper part of the cup. Apart from the fact that attention to the cup is only required occasionally—every month or so on line shafting, filling being necessary about once a year—the automatic increase of lubricant, should the bearing become warm, is a valuable feature.

Packings for valves and joints of all descriptions are found at many stands.

The J. D. Insulating and Refrigerating Co., Ltd., exhibit a hinge and fastener for doors of refrigerators which ought to be of value on chemical plant. That member of the hinge which is fixed to the door is in two parts, one sliding over the other and held in position by nuts. Should the door sag through wear or other causes, a simple adjustment of the nuts enables the door to close accurately again. The fastener handle is provided with a cam to move the latch and make a tight joint. On opening, the latch may be used for "levering" the door opening when it is cemented in position.

Pipe bending machines are shown at several stands, the well known Kennedy machine at the stand of Mr. Kennedy, and another by Messrs. Major, Robinson & Co., Ltd. A complete hydraulic plant for the purpose is shown by Messrs. T. B. Bilton & Sons, Ltd., and a plant for very thin tubing by Messrs. P. Wilkinson & Sons.

A simple hand machine which deserves special mention on account of its simplicity and cost, and also because coils may be readily made or pipes bent in position by it, is shown by Messrs. Skylux, Ltd.

Measurement, regulation and record keeping are fundamental points in good management and essentials to determine improvement. The Lea Recorder Co., Ltd., show their new "Cubi" meter for coal or similar material. Such a meter enables the engineer in charge to know the amount of coal burnt in every shift. A plate conveyor carries a bed of coal under a hinged flap and a recording mechanism registers the volume of coal passing by integrating the speed of the conveyor with the position of the flap. To demonstrate the practical accuracy of this method the firm shows a volume of small coal perfectly balanced by an equal volume of coal of a larger size.

A simpler type of coal measurer is shown by Messrs. George Kent, Ltd. A spiral vane is inserted in the casing carrying the coal to the boilers or furnaces. The number of revolutions made by the vane determines the volume of coal passing, and is registered by a suitable mechanism. On the same stand may be seen water meters of the Venturi, rotary and piston types for which this firm is justly celebrated.

An interesting instrument—the "Servis Recorder"—is shown by Messrs. Bramco, Ltd. It consists of a small circular box, containing a pendulum and also a clock movement actuating a recording disc of paper. The box is attached to any moving or vibrating part of a machine, lorry, etc. When the particular machine is at work the pendulum vibrates and a point on it marks the registering disc. A complete record is thus obtained of the actual working time of any machine.

The Aster Remote Level Indicator exhibited by the Aster Engineering Co., Ltd., deserves attention. A closed reservoir suspended from a spring balance is connected by flexible piping to the tank, still or boiler above and below the fluid level. It is obvious that the reading of the spring balance will be determined by the level of the fluid and may be transmitted electrically to any place required.

(*To be continued.*)

Dr. A. A. Noyes, director of the Gates Chemical Laboratory of the California Institute of Technology, has been elected an honorary fellow of the Royal Society of Edinburgh.

CORRESPONDENCE

HAFNIUM OR CELTIUM ?

Sir,—According to my opinion, one of the most important questions is whether the element possessing the Moseley No. 72 is to be called Celtium or Hafnium. Having devoted forty-six years to the theoretical and practical study of the elements of the rare-earth series (I was introduced to it in Bunsen's laboratory in 1878), I think that I am enabled to add something to the elucidation of the question. *Celtium* was discovered by Urbain in 1911. He photographed its spectrum, but, unfortunately, he published the wave-lengths of the strong lines only and not of the weak ones. It may be doubted whether the years 1911-12 are the real birthday of Celtium, but most certainly this element, the Moseley number of which is 72, was rediscovered or discovered by Dauvillier and Urbain in spring, 1922 (*cf. Nature*, June 17, 1922), by its Röntgen spectrum (*l.c.*, May 22, 1922).

This discovery was confirmed more than half a year later, but in spite of it Messrs. Coster and Hevesey have used the same method and obtained the same result, though the lines were measured a little more accurately (later on the lines were measured with greater accuracy by Dauvillier and Urbain); the two Danish physicists declare this "72" element a new one, and give it the new name "Hafnium."

A polemic took place between Urbain and the Danish physicists, but only a chemist who is a specialist in this department (a pretty difficult one) is able to see that splendid physicists may show a great want of a truly "chemical sense." First of all they use the names, "Aldebaranium" and "Cassiopeium," in spite of the fact that the International Committee for Atomic Weights has declared eleven years ago, under the presidency of Ostwald, that the names given by the first discoverer, (Neo) Ytterbium and Lutecium, must be adopted, Urbain having the priority of their discovery.

Messrs. Coster and Hevesey give an historical account of the discovery of "new" elements in zircon, but they ignore the names of Linnemann and of Pribram. Equally in their history of the splitting up of Marignac's Ytterbium they ignore the important fact that Nilson, when he discovered Scandium in 1879, not having it quite pure (free from Yb), concluded that it is a tetravalent earth-element with the atomic weight, Sc=180 (*i.e.*, to-day Moseley's No. 72). One of the leaders in the chemistry of the rare-earths could not distinguish whether really this element is ter- or tetra-valent, the earth, R_2O_3 or RO_2. Really Sc more resembles Th than La.

And the Danish physicists regard it as a great sin that Urbain regarded his celtium as a rare-earth element.

Messrs. Coster and Hevesey say that "hafnium" possesses physical and chemical properties quite different from those ascribed to a rare-earth element celtium (*Nature*, April 7). But if you ask (or look for) what these chemical properties are you find almost nothing. From the English articles we learn that it is easily separated from Zr, but only in the recent article in the *Chemiker-Zeitung* do they say "by fractional crystallisation of a salt." Only one more very unimportant property is given: that it forms a phosphate insoluble in water. Well, a look into an elementary text-book of qualitative analysis would have convinced the said physicists that all elements form insoluble phosphates—except the alkalis. Messrs. Coster and Hevesey always speak of their "hafnium" as being an analogue of zirconium, but they never say that its higher analogue is thorium and that it must possess properties lying between the two elements :—

IV	Zr	Ct-Hf	Th
	90	180	232

But we must not forget that Th, being more positive, is quantitatively precipitated as oxalate.

The chief "chemical argument" of Coster and Hevesey against Urbain is that the solutions of Hf are not precipitated by oxalic acid. It may be that in certain circumstances it is true of the pure salt solutions (see the analogous behaviour of Zr), but if they conclude that the fractions in which celtium was found by Urbain were purified by precipitation with oxalic acid and could not therefore contain any element 72, they are perfectly wrong. An element having the properties between Zr and Th must be precipitated by oxalic acid when other rare earths are present and will go down with them into the precipitate. So this great and heavy "chemical" argument disappears like fog.

But last, not least, Messrs. Hansen and Werner have measured the part of the spectrum lying between 2559-3497 A.U., obtained with a one-prism Hilger quartz spectrograph, and give the wave-lengths for 52 "hafnium" lines. I beg to direct the attention to the fact that some of the lines absolutely coincide with the Yb ("Ad") lines measured by Exner and Hatschek in 1911 with great exactness, other lines come extremely near to lines of Yb, Lu and Zr—*i.e.*, within the limits of experimental error due to a one-prism spectrograph.

We must conclude that the said physicists do not know the literature of the subject in question: they do not know the important work published by Exner and Hatschek as long as twelve years ago. The only work they quote is the dissertation of Bachem on the zirconium spectrum published in Bonn (1910), but the lines do not seem to be determined with great exactness.

One other chief argument of the Danish physicists is that the lines (X-ray) observed by Dauvillier and Urbain are not hafnium lines. No proof is given of this assertion, and Coster and Hevesey do not say what these lines, identical with their own, are. They are certainly not lutecium lines.

It may be that the lines of Coster and Hevesey were stronger than those of Dauvillier and Urbain, but when one scientist discovers weaker lines and another scientist stronger lines more than half a year later, is the second scientist to be regarded the true discoverer ?

I beg to ask, what is the good of putting down in print such alternatives as "Es musste demnach entweder die Theorie von Bohr unrichtig sein oder aber die Identifizierung der seltenen Erde Celtium mit dem Element 72." ?

I am a great admirer of Professor Bohr's theory of the atomic structure, but I think the authors would have done better not to mention his name in this connexion, for every rare-earth chemist knows that this "tail" of the fractionation—this most soluble portion—contains a mixture of trivalent and tetravalent earths which are not easily distinguished at once.

Except the X-ray spectrum found by Dauvillier and Urbain, and confirmed by Coster and Hevesey, we have only an incomplete spectrum by Hansen and Werner. No other physical property was determined up to this time (*e.g.*, specific gravity) and chemically this element is very insufficiently characterised. No atomic weight determination is known, and not one salt (except the phosphate) is described.

My opinion is that Prof. Urbain is the real discoverer of celtium and that there is no hafnium.—I am, Sir, etc.,

Prof. Bohuslav Brauner

The University, Prague

PERSONALIA

It is announced that during the meeting of the British Association in Liverpool, the University of Liverpool will confer the honorary degree of D.Sc. upon Sir E. Rutherford, president of the Association; Mr. G. H. Griffiths, treasurer of the Association; and Professors J. C. Maclennan, Neils Bohr and G. M. Lewis, and Dr. J. Schmidt.

The American Chemical Society announces that a trust fund for establishing a fellowship in biological chemistry in the College of Physicians and Surgeons, Columbia University, to be named in honour of the founder, William John Gies, will be presented at the twenty-fifth anniversary of that department on October 1. The committee will also present to Prof. Gies an illuminated book containing letters of appreciation from former students, and from friends in the United States and in Europe.

* * *

From Pittsburg the death is announced of W. F. McCook, founder and president of the Pittsburg Steel Co.

NEWS AND NOTES

SOUTH AFRICA

Production of Vanadium Ore

The *South African Journal of Industries* reports that the two consignments of 25 and 30 tons, respectively, of vanadinite concentrate, averaging 13 per cent. V_2O_5, from the Kaffirs' Krall mine in the Transvaal, constitute the first important shipment of this ore from the Union.

UNITED STATES

Mica in 1921

Mica was produced in 1921 in eight States, the total sales amounting to 2948 short tons, valued at $175,362 and including 741,845 lb. of sheet and 2577 t. of scrap mica. The sales of sheet mica represented a decrease of 56 per cent. in quantity and 78 per cent. in value, compared with decreases of 55 per cent. in quantity and 66 per cent. in value shown by scrap mica. Imports of sheet mica were 164 t. and of splittings 646 t., so that, estimating the export at 70 t., the apparent consumption of sheet mica was 1111 t.—(*Cf. J.*, 1922, 453 R.)

FRANCE

Société Française de Physique

To celebrate its fiftieth anniversary, the French Physical Society is organising a national exhibition to be held in Paris, at the Grand Palais, from November 30 to December 17. The exhibits, classed in nineteen groups, will illustrate the scientific, industrial and commercial applications of physical science, and will include, *inter alia*, apparatus for experimental physics and for biological and physiological physics, electrical and electrochemical apparatus, glassware, insulators, apparatus for optics, photography and the study of light, rare and compressed gases, heat, metallurgy, and measuring and controlling apparatus.

GENERAL

Production of Essential Oils from Citrus Fruits

This industry is centred mainly round the Mediterranean basin and in the British West Indies. Italy is probably the largest producer of essential oils of citrus fruits, the production in 1920 (latest available statistics) being 889,500 kg. and including 635,690 kg. of lemon oil and 111,170 kg. of bergamot oil. Neroli oil is produced in Algeria, and certain amounts are produced in France and Spain. Dominica and other islands of the Leeward Island group produce lime products as well as orange oil. Imports of citrus oils into Great Britain totalled 2,014,325 ℔. in 1921. The consumption in the United States is increasing, imports of lemon oil alone having risen from 450,000 ℔. before the war to nearly 700,000 ℔. in 1922. It is reported that the industrial distillation of citrus oils is being established in Southern India in Mysore.—(*U.S. Com. Rep., May* 14, 1923.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Sept.* 7)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina ..	Tinplate, corrugated iron	287
„ ..	Steel piping (tender)	8652/F.L./E.C./2
Australia ..	Steel girders (tender)	12037/E.D./E.C./2
British India	Steel, galvanised sheets (tender) ..	*
Canada ..	Steel tubes	12009/E.D./E.C./2

New Zealand	Paper (tender) ..	12019/E.D./M.P.
Norway ..	Iron tubes and fittings	852/15/F.G./E.C./2
South Africa	Tar, tar substitute (tender)	11996/E.D./C.C./2

* The Madras and Southern Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, S.W. 1.

TARIFF CUSTOMS EXCISE

Denmark.—The present issue contains information regarding the marking of imported rubber goods.

Esthonia.—Oil-shale distillation plants and their equipment are admitted duty-free.

Italy.—The manufacturing tax on spirits has been raised, and is now also leviable on methyl alcohol and all other refined alcohols, except ethyl alcohol.

New Zealand.—Glass bottles are now subject to duty, and leathers, goatskins and kidskins are duty-free.

South Africa.—Rebates of duties are allowed on turpentine, oils, tinfoil and motor spirit.

United States.—An investigation is taking place on the differences in cost of production, etc., in respect of metallic magnesium, magnesium alloys, tubing and wire, under the "flexible tariff" regulations.

REVIEWS

TABELLE UND ANLEITUNG ZUR ERMITTELUNG DES FETTGEHALTES NACH VEREINFACHTEM VERFAHREN IN NAHRUNGSMITTELN. FUTTERMITTELN UND GEBRAUCHSGEGENSTANDEN. *By* DR. J. GROSSFELD. *Pp.* 12. *Berlin : J. Springer*, 1923. *Price* 1*s*.

The author explains that the favourable reception which his method has met with, on the part of his colleagues, has caused him to write a short description of what he deems to be a simpler and more rapid process than the older Soxhlet method.

He proposes, for the rapid estimation of fat in such substances as butter, margarine, soap, cheese, cocoa, and baked goods, to dissolve the fat in a given quantity of trichlorethylene (100 c.c.) and to evaporate an aliquot portion (25 c.c.) of the fatty extract. Particulars of the necessary modifications of the method for use with various substances are given. For the convenience of anyone who is sufficiently impressed to use the method, a comprehensive table is appended for the correction for the volume of fat in 25 c.c. of the fatty solution evaporated. E. R. BOLTON

ANLEITUNG ZUR ORGANISCHEN QUALITATIVEN ANALYSE. *By* HERMANN STAUDINGER. *Pp. xiv*+94. *Berlin : Julius Springer*, 1923. *Price* 3*s*.

Inorganic qualitative analysis is apt to degenerate into the mere routine carrying out of a scheme given in the " tables," and for this reason loses much of its educational value. No such systematic tables can be drawn up for dealing with organic products, and consequently the student is compelled to use his own initiative in devising means of separation and identification. For this reason the educational value of organic " spots " is high, and in this country a considerable portion of the student's time has always been devoted to work of this nature. This has not been the case in Germany, but the appearance of Professor Staudinger's book suggests that the value of qualitative organic work is now receiving wider recognition.

Since it is impossible to draw up a systematic scheme which will lead to the identification of any organic compound, books on qualitative organic analysis must be confined to suggesting tests which will gradually narrow down the search and finally lead to identification by the preparation of suitable derivatives. In the book under review organic compounds are first divided into two broad classes, viz., L.F. (leichtflüchtige) and S.F. (schwerflüchtige) Verbindungen, the former consisting of those compounds which boil below 140°. The L.F. class is again subdivided according to the solubility of the compound in water and ether, and finally according to the elements present. The subdivision of the S.F. class is carried out on similar lines, although in greater detail. It will thus be seen that compounds are classified according to their physical properties, rather than according to their chemical reactions, a mistake from an educational point of view. Under each sub-division suggestions are made for the preparation of derivatives. These suggestions are very brief and it is extremely improbable that the average student could carry out the great majority of the preparations without very much further information. For such information the reader is referred to " L," but neither in the list of abbreviations (which is given as a footnote on page 25) nor elsewhere is any explanation of " L " given.

No tables of melting points or boiling points are given, it apparently being intended that the student should refer to Richter's " Lexikon " for information of this nature. This no doubt has the great advantage of familiarising him with the literature, but the time occupied is apt to be excessive, especially when it is merely desired to ascertain whether a given derivative is a solid or a liquid before attempting to prepare it.

The book is well printed on reasonably good paper and is very free from typographical errors. It is not, however, likely to come into general use in this country.

E. DE BARRY BARNETT

DIZIONARIO DI MERCEOLOGIA E DI CHIMICA APPLICATA. *By* PROF. G. V. VILLAVECCHIA, *with the assistance of* PROFS. G. FABRIS, G. ROSSI, A. BIANCHI, *and* R. BELASIA. *Fourth edition, revised and enlarged. Vol. I. Abelmosco-Cuscuta. Pp.* 872. *Milan : U. Hoepli*, 1923. *Price* 36 *lire*.

The issue of a fourth edition of this dictionary of chemical and commercial products testifies to the public appreciation of its worth. Under headings which cover a great variety of subjects, ranging from anthracene, cosmetic waters and plums to white lead, paper, timber, and camphor, are given the names of the product dealt with in various languages, its chemical formula (where possible), its origin, physical and chemical properties, purity, adulteration, uses and other general information. Although the range of subjects covered is so extensive, errors of fact appear to be gratifyingly absent, though in certain cases, *e.g.*, under " Coke," figures need revision. Much of the information of production, trade and customs duties given in small type at the end of each section, is not sufficiently recent to be of much value (though more recent information is given in an appendix), and it is to be hoped that the three forthcoming volumes will be printed on better paper than this one. The dictionary will undoubtedly prove a useful work of reference to scientific as well as commercial readers.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There is no appreciable change in market conditions. Export business is largely confined to Heavy Chemicals and is being maintained. The Home trade conditions show a slight improvement.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw.	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton makers' works.
Ammonia Alkali	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	6¼d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt· wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£8—£10 per ton, according to grade. Market quieter.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% P.O. Fairly regular demand.
Solvent	6s. per gall. 40% O.P. Demand steady.
Wood Tar	£5—£6 10s. per ton, according to grade. Market quiet.
Brown Sugar of Lead	£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.—1s. 2½d. per lb. Good demand. Market firmer.
Crude 60's	3s. 3d.—3s. 6d. per gall. Good demand for spot delivery.
Acid Cresylic—97/99	2s.—2s. 5½d. per gall.
Pale 95%	1s. 10d.—2s. 5d. per gall. Market weaker.
Dark	1s. 10d.—2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price.
Anthracene Oil—	
Strained	8¾d.—10d. per gall. Supply short.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	1s. 1½d. per gall.
Standard Motor	1s. 6½d. per gall. delivered buyer's works.
Pure	2s.—2s. 1d. per gall. d/d. buyer's works.

Toluole—90%	1s. 9d.—1s. 10d. per gall.
Pure	2s. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9¾d. per gall. Fair enquiry.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 5d.—1s. 6d. per gall.
Solvent 90/190	1s. 3d.—1s. 6½d. per gall.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Supply short.
Whizzed or hot pressed	£11—£12 per ton.
Naphthalene—	
Crystals	£20 per ton.
Flaked	£20 10s. per ton.
Pitch, medium soft	132s. 6d.—145s. per ton. Market quiet.
Pyridine—90/140	19s.—20s. per gall. Market very strong.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 10d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 7d.—1s. 8d. per lb. Market weaker.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—10d. per lb. naked at works. Price hardening.
Aniline Salts	9½d.—10d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 0d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Prices firm with a good steady demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d.—8d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 1d.—3s. 2d. per lb. Distinctly firmer in price.
Acid, Benzoic	2s. 3d. per lb. Some German makers are stated to be out of stock.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 5½d.—1s. 6½d. per lb., less 5%.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb., according to quantity.
Acid, Salicyclic	2s. 2d.—2s. 4d. per lb.
Acid, Tannic	3s. 3d. per lb.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market continues weak.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. Market very quiet.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	17s. per lb.
Benzonaphthol	4s. 6d. per lb.
Bismuth Salts	A steady market.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	6½d. per lb.
Ammonium	7d. ,, ,,
Sodium	7½d. ,, ,,
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.
Chloral Hydrate	3s. 9d.—4s. per lb. Somewhat firmer.
Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.
Creosote Carbonate	8s. lb. Demand negligible.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	3s. 6d. per lb. Continental prices higher.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s. per lb. Competition has lowered price.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality & quantity.
Menthol	A.B.R. recryst. B.P. 64s. per lb.

Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 4d. per lb.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid: Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9d., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 5d. per lb.
Paraldehyde	1s. 4d. per lb. in demijohns, 1s. 4½d. in bottles.
Phenacetin	6s. per lb., with slight shading for large quantity.
Phenazone	7s. per lb.
Phenolphthalein	6s. 6d.—6s. 9d. per lb.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	3s.—3s. 6d. per lb., according to quantity.
Potass. Iodide	15s. 8d.—15s. 11d. per lb. Good market and strong demand for Japan.
Potass. Metabisulphite	5d. per lb. Spot value somewhat lower.
Potass. Permanganate	10d. per lb. in drums.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. in bulk packages. Steady demand.
Resorcin	5s. 6d. per lb.
Salol	3s. per lb.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 6d. per lb. for spot supplies. German makers quote 1s. 11d. f.o.b., equal to 2s. 8d. per lb. here.
Sod. Citrate, B.P.C. 1923	2s. 3d. per lb.
Sod. Hyposulphite—Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Demand not very brisk.
Sod. Salicylate	Powder 2s. 5d.—2s. 7d. per lb., and Crystal at 2s. 7d.—2s. 9d. per lb.
Sod. Sulphite, anhydrous	£27 10s.—£29 per ton, according to quantity for home trade, 1-cwt. packages included. Export prices from £25—£26 10s. per ton.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.	
Aubepine	13s. ,, ,,	
Amyl Acetate	3s. ,, ,,	
Amyl Butyrate	7s. 3d. ,, ,,	
Amyl Salicylate	3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,	
Benzyl Alcohol free from Chlorine	3s. ,, ,,	
Benzaldehyde free from Chlorine	3s. ,, ,,	
Benzyl Benzoate	3s. ,, ,,	
Cinnamic Aldehyde Natural	17s. 6d. ,, ,,	
Coumarin	18s. ,, ,,	
Citronellol	19s. 6d. ,, ,,	
Citral	9s. 6d. ,, ,,	
Ethyl Cinnamate	10s. ,, ,,	
Ethyl Phthalate	3s. 9d. ,, ,,	
Eugenol	10s. ,, ,,	
Geraniol (Palmarosa)	35s. ,, ,,	Advanced.
Geraniol	5s. 6d.—12s. 6d. per lb.	
Heliotropine	8s. per lb.	
Iso Eugenol	15s. per lb.	
Linalol ex Bois de Rose	18s. 6d. ,, ,,	
Linalyl Acetate	21s. ,, ,,	
Methyl Anthranilate	7s. ,, ,,	
Methyl Benzoate	6s. ,, ,,	
Musk Xylol	11s. ,, ,,	
Phenyl Ethyl Acetate	10s. ,, ,,	
Phenyl Ethyl Alcohol	16s. ,, ,,	
Rhodinol	45s. ,, ,,	
Safrol	2s. 1d. ,, ,,	
Terpineol	3s. ,, ,,	
Vanillin	22s. 3d.—23s. 6d. per lb. Firm with steady demand.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	1s. 10½d. ,, ,,	
Bergamot Oil	12s. 6d. ,, ,,	spot.
Bourbon Geranium Oil	30s. ,, ,,	
Cananga Oil, Java	9s. ,, ,,	
Cinnamon Oil, Leaf	4½d. per oz.	
Cassia Oil 80/85%	12s. 6d. per lb.	
Citronella Oil—		
Java 85/90%	4s. 2d. ,, ,,	
Ceylon	2s. 10d. ,, ,,	
Clove Oil	8s. 6d. ,, ,,	
Eucalyptus Oil 70/75%	2s. 3d. ,, ,,	
Lavender Oil	18s. 6d. ,, ,,	
Lemon Oil	2s. 10d. ,, ,,	
Lemongrass Oil	2¾d. per oz.	
Orange Oil, Sweet	12s. 6d. per lb.	
Otto of Rose Oil—		
Bulgarian	34s. per oz.	
Anatolian	24s. per oz.	
Palma Rosa Oil	22s. 6d. per lb.	
Peppermint Oil—		
English	80s. ,, ,,	
Wayne Country	14s. 9d. ,, ,,	
Japanese	13s. ,, ,,	Market rising owing to speculation.
Petitgrain Oil	7s. 6d. per lb.	

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, SEPTEMBER 21, 1923 No. 38

EDITORIAL

THE meeting of the British Association at Liverpool has been a conspicuous success. The attendance was almost, if not quite, a record; the organisation was excellent, reflecting great credit on the local secretaries and committees, the papers and discussions were of a high order and the weather all that could be desired, and better than could be expected. The address of the President, Sir Ernest Rutherford, was broadcasted, and those of us who were in London were able to hear with unusual distinctness every syllable and every change of intonation. If other cities were as well served in this respect as London, the achievement must have given universal satisfaction. The sectional meetings were in many cases full to overflowing, and the public lectures were equally crowded. The British Association made a successful attempt to spread its influence over a wide area; by arrangement with various local societies it organised a series of lectures not only in Liverpool but also in some of the towns in the vicinity. For instance, Sir John Russell gave a lecture in Warrington on plant foods. Sir John Russell, who is in charge of the Experimental Station at Rothamsted, has not only a familiarity with the subject and its history which is probably unique, but he has also the gift—or has taken pains to acquire the art—of explaining his facts in simple and intelligible terms. He traced our knowledge of crops and their increase from the early work of Lawes and Gilbert to the most recent experiments made in the summer of 1923. To many of his audience one of the most interesting features was his account of the value of straw wetted by a spray of water and allowed to ferment. If suitable bacteria are available, the fermented straw seems to have great value as a manure, and it is to be hoped that a detailed account of this will be easily accessible at an early date. Another point of interest was the considerable effect on the growth of the plants of very small quantities of boron, manganese, silicon and some other elements whose importance as constituents of the soil is not usually recognised. Even those whose talk is of the breed of bullocks, as the Scriptures say, could have understood the lecture and profited by it, and we feel sure that in the future such local lectures in the electronic orbits surrounding the nucleus of the meeting itself will be widely appreciated.

* * *

Some little time ago we published a letter from an anonymous correspondent, who, with a good deal of reason, objected to the introduction of the personal element into the discussion of scientific questions. Our correspondent, possibly desirous of being perfectly consistent, omitted to inform us of his identity. In this issue we print a letter from another correspondent who, it would seem, has also a liking for anonymity, as he too has omitted to disclose his identity. We cannot complain if some of those who contribute matter for inclusion in our correspondence columns think fit to utilise a *nom-de-plume*, but we must insist that this anonymity be limited to the printed page only and not extended to the editorial sanctum. In future we hope that our correspondents will, without exception, authenticate their letters by including their names and addresses, *though not necessarily for publication*. It is the universal editorial rule in such cases to apply, as the Persian proverb has it, the padlock of silence to the portals of speech, and though our correspondents make themselves known to us, they can still, if they wish, be content to blush unnamed in print. Our correspondence columns should in time be an interesting and important feature; there are many debatable and doubtful points in our pages, and our readers value very highly the corrections and suggestions which appear, one of which on the theory of the Stream-Line filter appears in this issue. Surface tension and surface action will be extremely important factors in the chemistry of the twentieth century.

SOME ASPECTS OF THE PHYSICAL CHEMISTRY OF INTERFACES*

By Prof. F. G. DONNAN, C.B.E., F.R.S.

It was at the last meeting at Liverpool, in 1896, that I first had the honour of attending a gathering of the British Association. Looking back on that meeting one can say now that it came at the dawn of a new era in the development of physico-chemical science. The X-rays had just been discovered by Rontgen. Perrin had proved experimentally (1895) that a negative electric charge was associated with the cathode rays and had surmised that these so-called " rays " were constituted by electricity in motion, thus corroborating Crookes' brilliant views of a decade earlier and demonstrating that Lenard was wrong. Sir J. J. Thomson had just begun that splendid series of researches which resulted not only in the complete elucidation of the nature of the cathode "rays," but also in the discovery of the negative electron as a constant, universal, and fundamental constituent of all matter. The discovery of the chemically inert elementary gases by Rayleigh and Ramsay had begun in 1894, and the series of investigations which finally led to the recognition of the radio-active transformations of atoms and to the discovery of the nature and constitution of the atom itself, were just beginning. During the last twenty-five years the influence of these discoveries on chemical science has been enormous. There has come about a fresh reunion of physics and chemistry, somewhat analogous to that which occurred in the days of Volta and Davy. During the two decades preceding 1896, physical science had been largely concerned with the phenomena of the " ether," with electric and magnetic fields, electromagnetic waves, and the identification of light and other forms of radiant energy as electromagnetic phenomena. Now that the physicists have brought physical science back to the close and intimate study of matter, physics and chemistry have come together again, and the old and homogenous science of " natural philosophy " has been reconstituted. It is time that the walls which divide our chemical and physical laboratories were broken down, and that the young men and women who come to our Universities to study physics *or* chemistry, should study the facts and principles of a fundamental science which includes both.

In recent years chemists, physicists and physiologists have paid much attention to the phenomena that occur at the surfaces or interfaces which separate different sorts of matter in bulk. During the last quarter of the nineteenth century, both J. Willard Gibbs and J. J. Thomson had shown clearly, though in different ways, the peculiar nature of these interfacial or transitional layers. It was evident that things could happen in these regions which did not occur in the more homogenous and uniform regions well inside the volume of matter in bulk. Such happenings might reveal molecular or atomic peculiarities which would be undetectable in the jostling throng of individuals inside. A surface or surface layer represents a sort of thin cross section which can be examined much more readily than any part of the inside bulk. It is indeed only within comparatively recent years that X-rays have provided a sufficiently fine probe for examining this bulk in the case of crystalline matter.

The living organisms of plants and animals are full of surfaces and membranes. What can happen at surfaces is therefore a matter of great importance for the science of living things. We are bound to hold as long as possible to the assumption that the physico-chemical manifestations of life can be explained in terms of the potentialities of action inherent in electrons, atoms, and molecules. The modes of action of ordered arrays and marshallings of atoms and molecules are of extreme interest, since such modes of action will constitute phenomena non-existent in a disordered multitude of the same atoms and molecules with exactly the same individual powers and potentialities. These phenomena may be intimately connected with the phenomena of living matter, and as the latter evidently require the existence of surfaces and membranes, the idea naturally suggests itself that the special arraying or ordering of individuals occurs at, and may start from, such surfaces.

An essential characteristic of this ordering or arraying may consist in *special orientation*. In the chemical and physical actions occurring in a volume of liquid whose bulk is large compared with its surface, the molecules or atoms probably move towards each other with every sort of orientation, no special type being privileged or distinguished. Should, however, some special orientation be characteristic of interfaces, then it is clear that such interfaces will exhibit new phenomena due to this special sort of arraying. Moreover, if we are dealing with molecules which are ionised into electrically polar constituents, or which, if not actually dissociated can be treated as electrically bi-polar, it follows that, if orientation occurs at interfaces and surfaces, then electrical double layers and electrical potential differences may be set up at such boundaries.

In the theories of Laplace, Gauss, and Poisson the field of force surrounding an attracting element or molecule was regarded as essentially uniform in its spatial relations, *i.e.*, the equipotential surfaces were regarded as concentric spheres with the molecule as a small element at the centre. The older "physical" theories of cohesion according to central forces with uniform orientation have been to some extent replaced, or at all events supplemented, by "chemical" theories according to which the attractive force-fields are highly localised round active chemical groups and atoms, are relatively minute in range, and can be saturated or "neutralised" by the atoms or groups of neighbouring or juxtaposed molecules.

---

* Presidential Address delivered before Section B (Chemistry) at the meeting of the British Association for the Advancement of Science held in Liverpool from September 12 to 19. (Abridged.)

Dr. W. B. Hardy has been the chief pioneer in developing these newer theories, having been led thereto by his researches on surface tension, surface films, composite liquid surfaces and static friction and lubrication. As the matter is very important I shall give two quotations from Hardy's scientific papers.

"The corpuscular theory of matter traces all material forces to the attraction or repulsion of foci of strain of two opposite types. All systems of these foci which have been considered would possess an unsymmetrical stray field—equipotential surfaces would not be disposed about the system in concentric shells. If the stray field of a molecule, that is of a complex of these atomic systems, be unsymmetrical, the surface layer of fluids and solids, which are close-packed states of matter, must differ from the interior mass in the orientation of the axes of the fields with respect to the normal to the surface, and so form a skin on the surface of a pure substance having all the molecules oriented in the same way instead of purely in random ways. The result would be the polarisation of the surface, and the surface of two different fluids would attract or repel one another according to the sign of their surfaces." (Hardy, 1912).

These ideas are even more clearly expressed in the following passage. "If the field of force about a molecule be not symmetrical, that is to say, if the equipotential surfaces do not form spheres about the centre of mass, the arrangement of the molecules of a pure fluid must be different at the surface from the purely random distribution which obtains on the average in the interior. The inwardly directed attractive force along the normal to the surface will orientate the molecules there. The surface film must therefore have a characteristic molecular architecture, and the condition of minimal potential involves two terms—one relating to the variation in density, the other to the orientation of the fields of force." (Hardy, 1913.)

Hardy thus bases the notion of molecular orientation at the surface on the existence of unsymmetrical fields of force surrounding the molecule; in other words, the parts of the molecule possessing the most powerful stray fields will be attracted inwards towards the bulk and thus cause a definite orientation of the whole molecule at the surface.

It seems that the cohesional forces are essentially chemical in origin and that they depend in large measure on the presence of "active" atoms or groups of atoms, namely, those possessing strong fields of "residual chemical affinity"; in other words, powerful and highly localised stray fields of electrical or electromagnetic force (or of both types). The existence of such atoms or atomic groups is strong presumptive evidence of the unsymmetrical fields of force postulated by Hardy and therefore of the molecular orientation at surfaces.

The conclusions drawn by Hardy have been amply confirmed by W. D. Harkins and his collaborators, who in a long series of accurate measurements of surface and interfacial tensions have found that with many organic liquids the "adhesional work" towards water is greatly increased by the presence of oxygen atoms (as in alcohols, acids, and aldehydes). They find that the very symmetrical halogen derivatives CCl_4 and $C_2H_4Br_2$ (which possess specially high values for their own cohesional work) give markedly low values for their adhesional work towards water, and that in the case of unsymmetrical molecules, the adhesional work towards water is determined by the presence of certain active atoms or atomic groups.

In his work on static friction and lubrication, Hardy has found that the influence of chemical constitution and the effects of active atomic groups are very pronounced. Thus, comparing aliphatic or open chain compounds, the coefficient of static friction falls (and the lubricating power increases) as we pass through the series hydrocarbon—alcohol—acid. The corresponding ester is in this case a much worse lubricant than the related acid or alcohol. These results suggest, as Hardy has indicated, that friction is caused by the molecular cohesion of surfaces, and that in the action of such lubricants the molecules are oriented with their long axes normal to the surface, whereby the active atomic groups play an important part in "taking up" or saturating a portion of the stray force-fields of the molecules of the solid surfaces, and in orienting and anchoring the lubricant molecules to these surfaces. Many facts lend strong support to Hardy's views. Thus it is true, I believe, that the addition of aliphatic esters improves the lubricating value of hydrocarbon oils, whilst H. Wells and W. Southcomb have demonstrated the marked improvement due to a small addition of a fatty acid. Recently W. E. Garner and S. S. Bhatnagar have shown that the interfacial tension between mercury and B.P. paraffin oil is markedly lowered by small additions of oleic acid; the oleic acid molecules are therefore absorbed or concentrated at the mercury-oil interface, an action which may well be due in part to the fixation and orientation of these molecules at the metal-oil interface.

This question of the orientation of molecules at the surfaces of liquids has been greatly extended in recent years by a detailed study of the extremely thin and invisible films formed by the primary spreading of oily substances on the surface of water. The late Lord Rayleigh showed many years ago that when olive oil forms one of these invisible films on water, there is no fall in surface tension until the surface concentration reaches a certain very small value. He made the highly interesting and important suggestion that this concentration marks the point where there is formed a continuous layer just one molecule thick. With olive oil, he found this critical thickness to be 10^{-7} cm., and concluded that this number represented the order of magnitude of the diameter of a molecule of the oil. Increase in surface concentration beyond this point causes the surface tension to fall, until a second point is reached, after which no further fall in surface tension occurs. Lord Rayleigh assumed that at the second point a layer two molecules thick is formed. The pioneer work of Lord Rayleigh was repeated and extended by H. Devaux and A. Marcelin, who showed the correctness of his first suggestion, namely, that the primary film consists of a *unimolecular* layer. It appears, however, that the fall in surface tension which he ascribed to the building up of a bimolecular layer, must be ascribed to the closer packing of the molecules of the unimolecular layer, and that the second point occurs when these molecules are packed as tightly as possible.

Instead of varying the surface concentration by adding more and more of the oily substance to a definite surface, we may attain the same end by means of a moving boundary and a variable surface, and study the relation between the force of surface-compression (difference between the surface tension of pure water and that of the contaminated surface) and the surface concentration. Although these researches had firmly established the theory of the formation of a unimolecular surface layer and therefore of the existence of a *new "two-dimensional" phase,* Langmuir made a very important advance by connecting this conception with the ideas of chemically active groups and molecular orientation. Influenced no doubt, by the ideas of Hardy, Langmuir reasoned that the formation of these primary unimolecular films must be due to the presence of active groups in the molecules, which are attracted inwards towards the water and thus cause the long open-chain molecules of the fatty acids to be oriented on the water surface with their long hydrocarbon axes vertical and side by side.

Working by means of the method of Devaux, Langmuir put these ideas to the test of experiment, and determined the internal molecular dimensions of a unimolecular layer. His results agree wonderfully well, both with the idea of a unimolecular layer and with that of molecular orientation. If we calculate the average distance between two adjacent carbon atoms in palmitic, stearic and cerotic acids, we obtain a value of $1{\cdot}4\times10^{-8}$ cm. Now this distance must be of the order of magnitude of the distance between the centres of the carbon atoms in the crystal structure of a diamond. This latter distance is known to be $1{\cdot}52\times10^{-8}$ cm. The agreement is striking.

These regularly oriented and unimolecular surface films on water have been recently investigated by N. K. Adam, who, from a closer analysis of the relationship between the force of surface compression and the surface concentration (expressed as area occupied per molecule), has shown that a distinction must be made between the close packing of the polar or active end groups (head groups) of the molecules and the subsequent close packing of the hydrocarbon chains. Adam's results provide an ample confirmation of the theory of unimolecular films of juxtaposed and oriented molecules. If we calculate the average distance between two carbon atoms for the following four acids, we obtain the following results in cm. $\times10^{-8}$:— Myristic acid, 1·6; pentadecylic acid, 1·6; stearic acid, 1·5; behenic acid, 1·5.

Concerning this point some very interesting results have been recently obtained in Sir William Bragg's laboratory by Dr. A. Müller, who has examined layers of crystallised fatty acids on glass plates by an X-ray photographic method. From these results it appears that the unit cell is a long prism, the cross section of which remains constant for the substances investigated, whilst the length of the prism increases linearly with the number of carbon atoms in the molecule. The increase in length of the unit prism per carbon atom in the molecule is found to be $2{\cdot}0\times10^{-8}$ cm. Since it appears likely that there are *two* molecules arranged along the long axis of each unit cell (prism), it would follow that the increase in the length of the molecule per carbon atom added is $1{\cdot}0\times10^{-8}$ cm. Comparing this result with the value for the distance between the carbon centres in the diamond lattice, the carbon atoms in the long hydrocarbon chains of the higher saturated fatty acids appear to be arranged in a zig-zag, or more probably in a spiral or helix. If this be so, the closer packing or compression of the juxtaposed molecules in the unimolecular films, as indicated by Devaux, Langmuir, and Adam, may be explained to some extent by the straightening out of these zig-zags, or perhaps by the "elastic compression" of the helices.

As Langmuir pointed out, the question of the formation of unimolecular surface films can be attacked in a different manner. It is known that gases or vapours can be condensed or adsorbed by solid and liquid surfaces. The question then arises, does the formation of primary unimolecular films ever occur in such cases? Hardy made the suggestion that the formation of the primary unimolecular film in the spreading of oily substances on water might be due to adsorption from the vapour. To examine this question, Mr. T. Iredale has recently measured in my laboratory the fall in the surface tension of mercury caused by exposing a fresh mercury surface to vapours of increasing partial pressure. Working with the vapour of methyl acetate, Iredale found by applying Gibbs' formula that at a temperature of 26° C. and a partial pressure of 62 mm. of mercury, the excess surface concentration of the adsorbed vapour was $4{\cdot}5\times10^{-8}$ g. per square centimetre of surface. Therefore there are $0{\cdot}37\times10^{-15}$ molecules of methyl acetate adsorbed per square cm., and that the area per molecule is 27×10^{-16} sq. cm. As under the conditions corresponding to this calculation the molecular surface layer was probably not quite saturated (in the unimolecular sense), we may expect the value found to be of the same order of magnitude but somewhat greater than the values found by Adam for the cross section of the head group of the higher saturated fatty acids (25×10^{-16}) and of the esters (22×10^{-16} for ethyl palmitate and ethyl behenate). We may, therefore, say that Iredale's results appear to indicate the formation of a primary unimolecular layer built up by adsorption from the vapour phase.

Let us now consider another type of formation of surface layers at the surfaces of liquids—namely, the case where a substance dissolved in a liquid concentrates preferentially at the liquid-air or liquid-vapour interface. Gibbs, and later J. J. Thomson, have shown that if a dissolved substance (in relatively dilute solution) lowers the surface tension, it will concentrate at the surface. In 1908 S. R. Milner applied the same method to aqueous solutions of sodium oleate, and arrived at a mean value of $1{\cdot}2\times10^{-10}$ gram mols. excess concentration per sq. cm. of surface. For a dilute solution, we can calculate q, the amount concentrated or "adsorbed" in the surface per sq. cm. (excess surface concentration) by making use of the equation of Gibbs,

$$q = -\frac{d\gamma}{d\mu}\ .$$

where γ=surface tension and μ=chemical potential of the adsorbed substance in the bulk of the solution. Writing $\mu=\mathrm{RT}\log a+k$, where a="activity" of the solute, and k is a quantity dependent only on the temperature and nature of the solute and solvent, $d\mu=\mathrm{R\,T}\,d\log a$, and so Gibbs' equation can be written in the form

$$q = -\frac{1}{\mathrm{RT}}\,\frac{d\gamma}{d\log a}.$$

If for very dilute solutions (or for so-called "ideal" solutions) we put $a=c$, we can write

$$q = -\frac{1}{\mathrm{RT}}\,\frac{d\gamma}{d\log c} = -\frac{c}{\mathrm{RT}}\,\frac{d\gamma}{dc}.$$

In this way Milner has calculated from Whatmough's data for aqueous solutions of acetic acid that the "saturation" value of q is $3{\cdot}3\times10^{-10}$ mols. per sq. cm., from which it follows that the area per molecule in the surface is 50×10^{-16} sq. cm. In a similar manner, Langmuir has calculated from B. de Szyszkowski's data for aqueous solutions of propionic, butyric, valeric, and caproic acids that the surface area per molecule adsorbed in the saturated layer is equal to 31×10^{-16} sq. cm., whilst Harkins has arrived from his own measurements for butyric acid at the value 36×10^{-16} sq. cm.

In 1911 Dr. J. T. Barker and myself made a direct determination of q for a solution of nonylic acid in water, which showed that for a practically saturated surface layer, the surface area per molecule is 26×10^{-16} sq. cm.

These various values are not very different from the values found by Langmuir and by Adam for the oriented unimolecular layers of practically insoluble fatty acids resting on the surface of water. That in the present case some of the values are larger might easily be explained on the ground that these adsorption layers are partially, or completely, in the state of "surface vapours." For Adam and Marcelin have recently made the important discovery that the unimolecular surface films investigated by them may pass rapidly on increase of temperature from the state of "solid" or "liquid" surface films to the state of "vaporised" surface films, in which the juxtaposed molecules become detached from each other and move about with a Brownian or quasi-molecular motion, probably communicated to them by the thermal agitation of the water molecules to which they are attached. The question as to whether the simplified form of Gibbs' equation yields a sufficiently accurate value for the excess surface concentration can scarcely be decided without more experimental data.

There is another very interesting phenomenon relating to the surfaces of liquids and solutions—namely, the existence of an electrical potential gradient or potential difference in the surface layer. These interfacial potential differences are of great importance, and play a fundamental rôle in determining the stability or instability of many colloidal states of matter. The liquid-gas interface offers the simplest case of such interfaces, and so the investigation of the potential differences which may exist at this interface is a matter of fundamental interest. In 1896 F. B. Kenrick developed, on the basis of earlier experiments of Bichat and Blondlot, an electrometric condenser method for the comparative determination of the gas-liquid P.D.'s. His results show that substances (such as the aliphatic alcohols and acids) which concentrate at the surface produce a very great change in the surface P.D., whilst highly dissociated univalent inorganic salts, such as KCl, do not. Kenrick's results have been much extended by an investigation carried out with the same type of apparatus by Prof.

T. Thorwaldson in my laboratory. The general result of these experiments can be described in the following terms :—

Consider the system :

Aqueous Solution of KCl (conc.=c)	Air	Aqueous Solution of KCl (conc.=c)
A		B

The positive potential of A will be equal to that of B. If we now add to the solution B a small quantity of a substance S (generally a a non-electrolyte or weak electrolyte) which has a strong tendency to concentrate at the air-B interface, it is found that the positive potential of A rises markedly above that of B, the value of the quantity, positive potential of A minus that of B, varying with the concentration of S in the way that is characteristic of adsorption phenomena. What is the interpretation of this phenomenon ? If we were to assume that there was practically no P.D. at the interface A-air, it would follow that the effect of S is to make the positive potential of the bulk of B markedly below that of the air. The same result would follow if we were to assume that at the interface A-air there exists a P.D. which makes the positive potential of the bulk of A markedly below that of the air outside. Both these assumptions would lead to the conclusion that in the surface layer of the solution at the A-air interface there must exist either no electrical double layer, or else one with its *positive* half oriented towards the air side. Now Quincke has shown that a bubble of air in water placed in an electrical potential gradient travels towards the anode—*i.e.*, the bubble behaves as if it were negatively charged. From this it would follow that the P.D. at the air-water interface is such that the *negative* half lies towards the air side. As an electrolyte such as KCl is negatively adsorbed at an air-liquid surface, it is probable that a P.D. of the character indicated by Quincke's experiment exists at the A-air interface. If we accept this conclusion, it follows that the effect of S is markedly to *reduce* this P.D. (or to reverse it). Now the P.D. at the air-water interface is probably due to the existence of a double layer containing hydroxyl ions on the outside and hydrogen ions on the inside, or to oriented water molecules regarded as electrical bi-poles. If S is a non-electrolyte (or a substance which possesses little self-ionisation), we can understand why its concentration at the surface could result in the reduction of this P.D.

The experiments of Thorwaldson show that a substance such as the hydrochloride of methyl violet has a powerful effect on the P.D. at the air-water interface. It is probable that in this case the complex basic dye cation is drawn into, or " adsorbed " in, the outside layer next to the air, the result of this being a reduction or possibly reversal of the original potential difference.

Kenrick found that if gases such as hydrogen and coal gas be substituted for air, there is no effect on the surface P.D.

When liquids are sprayed or splashed, or when gases are bubbled through liquids, the gas often acquires an electrical charge, whilst the liquid acquires an opposite one (so-called " waterfall " electrification). Originally, Lenard thought that the effect was due to a " contact electrical " action between the gas and the liquid, whilst J. J. Thomson was inclined to ascribe it to a sort of partial chemical action between them. It is known that there are produced in the air or gas relatively slow-moving carriers, both positive and negative. Lenard has quite recently changed his views, and ascribes the origin of these carriers to the tearing off of very small portions of the outside layer of the electrical double layer existing in the surface of the liquid. It may be mentioned that Kenrick, Thorwaldson, and McTaggart came to the conclusion that the surface P.D.'s measured by them were not connected, or at all events not connected in any simple manner, with the phenomena of waterfall electrification. We may say, therefore, that if there be a relation between these two types of phenomena, it is a complicated and still largely obscure one.

The subjects which I have been discussing have an interesting bearing on the formation and stability of foams and froths. If air be violently churned up with water, only comparatively large bubbles are produced, and these quickly rise to the surface and burst. If now a very small quantity of a substance which concentrates at the air-water interface be added, an almost milk-white " air emulsion " of small bubbles is produced, which rise to the surface and produce a relatively durable froth. It is clear that the diminution in interfacial tension facilitates the subdivision or dispersal of the air. The existence of the surface layer will also confer a certain amount of stability on the resultant froth, since it will give rise to forces which resist the thinning of a bubble wall. Any sudden increase in the surface will produce a momentary diminution in the concentration or " thickness " of the surface layer, and hence a rise in surface tension, which will persist until the normal thickness or concentration is readjusted by diffusion of molecules from the inside volume—a process which in very dilute solution will occupy a perceptible time. That this explanation (due to the late Lord Rayleigh) is correct can be seen from the fact that very often stronger solutions of the same surface-active substance scarcely foam at all. In this case the readjustment of the equilibrium thickness or concentration of the surface layer occurs with such rapidity (owing to the greater concentration of the molecules in the inside volume) that practically no rise in surface tension, and hence no counteracting force, comes into play. These effects will be the more pronounced—other things being equal—the greater the mass and hence the smaller the motion of the solute units, as in the case of large molecules or colloidal micelles. It is probable, however, that the explanation of the stability of very durable forms, as, for example, those produced by the sea at the sea coast, by beer and stout, by aqueous solutions of soap or saponin, etc., is often more complex, and that we must seek it in the formation of very viscous or semi-rigid or gel-like membranes at the interface. Moreover, small solid particles may contribute to the stabilisation of a froth, as in the case of the "mineralised froths" of the ore flotation process; and the preferential aggregation of small particles in the interface between two phases has been demonstrated in the experiments of W. Reinders, F. B. Hofmann, and many others.

How far do the phenomena which are characteristic of a gas-liquid interface occur also at the interface between two immiscible or partially miscible liquids. Many years ago Gad and also Quincke showed that a fatty oil (such as olive oil) is very readily dispersed in the form of an emulsion by a dilute solution of caustic soda. Some experiments which I once made showed that a neutral hydrocarbon oil could be similarly emulsified in a dilute aqueous solution of alkali if one of the higher fatty acids was dissolved in it, whilst the lower fatty acids do not produce a similar action. It was shown that the action runs parallel to the lowering of interfacial tension and must be ascribed to the formation of a soap, which lowers the interfacial tension and concentrates at the interface.

If a substance which is dissolved in one liquid A, and which is practically insoluble in another liquid B, is found to have, in very dilute solutions, a strong effect in lowering the tension at the interface A-B, the following interesting questions arise:—

(1) What is the amount of the surface concentration or adsorption per sq. cm. of interface?
(2) Can it be calculated by means of the simplified Gibbs equation?
(3) How does the surface adsorption vary with the concentration?
(4) Does the "saturation" value correspond to the formation of a unimolecular layer?

Some of these questions were experimentally investigated in my laboratory by W. C. McC. Lewis. For the liquid A water was chosen, and for B a neutral hydrocarbon oil. Working with sodium glycocholate as the surface-active substance, it was found that the experimentally measured surface adsorption q was much greater than that calculated by means of the equation

$$q = -\frac{c}{RT}\frac{d\gamma}{dc}.$$

For example, a 0·2 per cent. aqueous solution at 16° C. gave a directly measured value of $q=5\times10^{-6}$ g. per sq. cm., whilst the calculated value was 5×10^{-8} g. per sq. cm., practically a hundred times smaller. A similar type of discrepancy was found for Congo Red and methyl orange. If we calculate from the experimentally found surface adsorption of sodium glycocholate the value of the surface area per molecule, we obtain about $0{\cdot}9\times10^{-16}$ sq. cm. A similar calculation for Congo Red gives a correspondingly low figure. If we compare these values with those previously obtained for the air-liquid surface, it is clear that in the present case we are not dealing with simple unimolecular layers, but with adsorption layers or films many molecules thick. But if we calculate from Lewis' results the surface area per molecule as deduced from the surface tension measurements by the simplified Gibbs formula, we arrive at values of the order of 90×10^{-16} (sodium glycocholate) and 100×10^{-16} (Congo Red). These are values which are consistent with the gradual building up of a unimolecular layer (of possibly heavily hydrated molecules or micelles). It is possible, therefore, that the Gibbs equation gives the surface concentration of the primary unimolecular "two dimensional" surface phase, and that any building up of further concentrations beyond this layer does not affect the surface tension. It is true that in the case of substances such as sodium glycocholate, and especially Congo Red, in aqueous solution, there is a considerable amount of uncertainity as to the nature and molecular weight of these substances as they exist, not only in the bulk of the solution, but especially in the surface phase. In a later investigation Lewis determined the surface adsorption of aniline at the interface mercury-aqueous alcoholic solution, and found in this case a very fair agreement between the observed and calculated results. This case is more favourable, since we can be in little doubt concerning the molecular weight of the solute units. The mean observed value for the surface adsorption was $2{\cdot}7\times10^{-8}$ g. per sq. cm. Hence the number of molecules per sq. cm. of interface $=2{\cdot}7/93\times10^{-8}\times6{\cdot}06\times10^{-23}=0{\cdot}17\times10^{-15}$, and the surface area per molecule$=58\times10^{-16}$ sq. cm. Langmuir's calculation from Worley's measurements of the surface tensions of aqueous solutions of aniline gives at the air-water surface the value 34×10^{-16} sq. cm. for the area per molecule of aniline. We may conclude, therefore, that Lewis' measurements in this case point to the building up of a primary unimolecular layer, unaccompanied by any further concentration or "condensation" of molecules or colloidal micelles.

The relation between surface adsorption and fall of interfacial tension at a mercury-water interface was further investigated by W. A. Patrick, who concluded that, although there was a correspondence between the two phenomena, the surface adsorption could not be calculated from the simplified Gibbs equation. If we were to accept this conclusion as correct, we might find an explanation either in the suggestion made above, or in the possible invalidity of conclusions drawn from the use of the simplified Gibbs equation; either because the simplifications introduced are not justified, or because the existence of electrical or other factors requires an extension or elaboration of the original equation. This matter has been discussed by Lewis, by A. W. Porter, and by various investigators of electro-capillary phenomena.

From very accurate measurements of the interfacial tensions of the aqueous solution-mercury interface, W. D. Harkins has calculated (by means of the simple Gibbs equation) that when the interface is saturated as regards butyric acid molecules coming from the aqueous solution, the surface area per molecule is 36×10^{-16} sq. cm.

Here, again, a calculation by means of the Gibbs equation seems to point to the formation of a primary unimolecular layer. Experiments similar to those of Lewis have been recently made by E. L. Griffin, who has measured directly the adsorption of soaps from aqueous solutions at a mineral oil-water interface. The average surface per molecule adsorbed was, for sodium oleate, 48×10^{-16} sq. cm., for potassium stearate, 27×10^{-16} sq. cm., and for potassium palmitate, 30×10^{-16} sq. cm.

These figures are very interesting, for they would appear to indicate the formation of unimolecular surface layers. It may be mentioned here that T. R. Brigges has investigated the adsorption of sodium oleate at a benzene-water interface, and finds that the amount of soap adsorbed at the interface increases rapidly at first with small increases in the concentration of the solution, and then remains very nearly constant while the concentration of the solution undergoes great increase. This is just what one would expect from the building up of a saturated surface or surface layer (whether unimolecular or otherwise).

We have seen that in the case of the air-water surface there exists an electrical separation or potential difference in the surface layer, and that certain substances can produce pronounced variations, or even reversals in sign, of this electrical double layer. It becomes a matter, therefore, of great interest to inquire whether similar phenomena occur at the interface between two immiscible liquids, and, if so, to ascertain whether such electrical charges or double layers bear any relation to the "stability" of pure emulsions, or fine dispersions of one liquid in another. It is well known that those disperse or finely heterogeneous states of matter known as colloidal solutions depend in part for their stability on the existence of such electrical potential differences. We might expect, therefore, that an investigation of these emulsion systems would throw some light on the general theory of what are called "suspensoid" or "lyophobic" colloidal states. Investigations with these objects in view were carried out some years ago in my laboratory by R. Ellis and F. Powis. The method employed was to measure directly by means of a microscope the motion of minute globules (suspended in water) under the influence of a known electric field. The experiments of Powis brought out the very important fact that when the interfacial P.D. (whether positive or negative) is above a certain value, which was about 0·03 volt for his conditions, the rate of coagulation or coherence of the oil drops is relatively small, but rapidly increases when the P.D. falls inside the zone –0·03 to +0·03 volt. Under definite conditions there exist, therefore, what we may, speaking broadly, call a *critical potential* and a *critical potential zone.* When the P.D. is outside this zone the emulsion is comparatively very "stable." Very small concentrations of electrolytes, which, as we have seen, increase the P.D., increase this stability. As soon as the concentration of any electrolyte is sufficient to bring the P.D. into the critical zone, the stability of the emulsion undergoes a sudden and very marked decrease, and relatively rapid coagulation occurs. Take, for example, the case of thorium chloride. On increasing the concentration we find that the interfacial P.D. traverses successively the following regions :—

(1) Above the critical value (and negative).
(2) Inside the critical zone (negative and positive).
(3) Above the critical value (and positive).
(4) Below the critical value (and positive).

In exact correspondence with this series we find that the emulsion goes through the following states :—

(1) Stable (oil particles "negative").
(2) Unstable and flocculating (oil particles negative or positive).
(3) Stable (oil particles positive).
(4) Unstable and flocculating (oil particles positive).

Here we see a very striking analogue and explanation of the phenomena observed by Joly in studying the effect of aluminium salts on the sedimentation of clays, and of the numerous examples of the so-called "irregular series" observed in the flocculation of suspensoid hydrosols by salts with polyvalent cations.

These studies of oil emulsions (and of the glass-water interface), by means of the micro-cataphoresis method, have thrown a great deal of light on many previously ill-understood points in the theory of colloids. If, for example, the P.D. between the particles of a suspensoid hydrosol and the aqueous fluid are not above the critical potential, coagulation will occur. But very small concentrations of certain electrolytes can raise the P.D. and stabilise the hydrosol. This is the explanation of the well-known "peptising" action. Higher concentrations of even the same electrolytes will reduce the P.D. below the critical potential, and produce flocculation. We see also that rapid coagulation will occur before the P.D. becomes zero. It is obvious, therefore, that coagulation of a lyophobic hydrosol will occur before the iso-electric point is reached, and that Hardy's famous rule requires revision.

There is not time or space at my disposal to enter into the much discussed question as to the inner mechanism of the action whereby ions (and electrically charged micelles) set up or vary the potential difference in the interfacial layer. According to Freundlich's original theory we must ascribe an independent effect to each ion, which will depend on the sign of its charge, its specific adsorbability, and electro-valency and the nature of the already existing double layer. A different theory was proposed by Freundlich in order to explain the results obtained in the electroendosmotic experiments of Elissafoff. According to this point of view, the "solid" surface acts chemically (as an acid, base, ampholyte, or salt), whereby it may dissociate off an ion or ions, and itself become an ionised surface. Invading foreign ions may then alter this ionisation equilibrium; or they may simply combine with the ionised surface and form neutral insoluble spots (compare the views of Freundlich, Gyemant, and Kolthoff). J. N. Mukherjee has suggested that ions are attached to the surface by chemical forces, and has attempted to work out an electro-kinetic theory of ion adsorption. It is probable that surfaces very often do act ionically or chemically, and that specific actions of this sort must often be taken into account in dealing with the great variety of material presented in the study of surface actions. Nevertheless, in the case of the hydrocarbon oil droplets studied by Ellis and Powis, or the gas-liquid interface studied by Kenrick, Thorwaldson, and McTaggart, any *specific* chemical activity or ionisation of the oil or gas would seem improbable. Any theory which attempts a general treatment of the problem must be prepared to deal with cases such as these.

Many measurements have been made of the potential differences between solids and liquids, or between pairs of immiscible (or partly miscible) liquids, using electrometric methods. Thus Haber and Klemensiewicz determined the potential difference at a glass-water solution interface, and found the glass to act like a hydrogen electrode. It will be at once obvious that these results are not in agreement with those obtained by cataphoretic and electroendosmotic methods. A somewhat similar type of discordance has been observed in the electrometric measurements of the potential difference between solid paraffin and an aqueous solution made by G. Borelius, and of the P.D.'s between pairs of liquids made by R. Beutner, E. Baur, and others. Freundlich and Gyemant have drawn attention to the fact that in all such electrometric measurements, where in the process of the measurement an electric current must pass from one phase to the other, we measure the total or "thermodynamic" potential difference between the phases in bulk, whereas in determinations by the methods of electroendosmose and cataphoresis, we measure only a portion of this total potential difference. These "electro-kinetic" P.D.'s, although of fundamental importance in relation to the stability of suspensoid (lyophobic) systems, need not, and in general will not, coincide in value with the total (thermodynamic) potential differences. I drew attention to a quite analogous difference in discussing the measurements of the potential differences at gas-water interfaces made by Kenrick and by McTaggart.

We may illustrate this point by considering the P.D. between two immiscible phases, L_1 and L_2, in equilibrium with each other, and each of which contains dissolved in it the electrolyte KA. If ϵ denote the positive potential of L_2 above L_1, and F the quantity of electricity associated with an ionic gram equivalent, then by a virtual variation of the equilibrium system it follows that

$$(\mu_K)_1-(\mu_K)_2=F\epsilon=(\mu_A)_2-(\mu_A)_1$$

where the subscripts refer to the cation or anion and to the phases L_1 or L_2 and the μ's denote the chemical potentials per gram equivalent (partial equivalent free energies) of the ionic constituents in the bulk of the two phases. Whatever may be the "electro-adsorption" or ion adsorption of K and A at the interface L_1—L_2, it is clear that ϵ depends only on the "bulk" values of the respective chemical potentials, which likewise determine the surface concentrations. If the phases L_1 and L_2 be not in equilibrium, then velocity or diffusional terms will enter into the equations, and the potential difference will be partly or wholly a "diffusional potential."

In dicussing the "stabilities" of hydrocarbon oil emulsions, it must not be forgotten that I was dealing with very dilute *suspensions* of oil in water, produced by mechanical agitation without the addition of any "emulsifier." I pointed out that in the emulsification of oils in water by means of soap, the soap lowers the interfacial tension and concentrates at the interface. When we wish to produce oil emulsions in the ordinary sense of the term we must use some such emulsifying agent, and for this purpose many substances are employed, such as soap, gum acacia, gelatin, casein, starch, etc. All these substances concentrate or condense on the surfaces of the oil globules. If we may regard these surface films as very mobile from the molecular-kinetic point of view, it is clear that they will confer an increased degree of stability on the emulsion. For any sudden decrease of interface (caused, for example, by coalescence or partial coalescence of two adjacent globules) will produce a momentary increase in the surface concentration or thickness of the adsorption layer, and so a decrease in the interfacial tension, if the surface layer is not saturated. It may require a perceptible time for the molecular-kinetic motion (especially in the case of large molecules or hydrated micelles) to readjust the equilibrium between the surface layer and the bulk.

It is probable, however, that the stability of the emulsion is in many cases due to the fact that the surface films possess a very viscous, quasi-rigid, or gel-like character, so that a more mechanical explanation is necessary. As S. U. Pickering showed, oils may be emulsified in water by the gels of certain basic salts ; and A. U. M. Schlaepfer has shown that emulsions of water in kerosene oil may be obtained by means of finely divided "carbon." Nevertheless, even in cases where an emulsifier is used, we may hope to succeed in obtaining a more precise physical analysis of the system. It is interesting in this connection to note that Mr. W. Pohl has recently found in my laboratory that when a neutral hydrocarbon oil is emulsified in water by means of sodium oleate, the electrical potential difference at the oil-water interface is almost doubled, and that the effects of alkalis and salts on this potential difference are very similar to those found when no emulsifier is employed.

I cannot conclude this account of certain aspects of surface actions and properties without making a passing, though all too brief, reference to the beautiful investigations of Sir George Beilby on the amorphous layer. He has shown that when the surface of crystalline matter is subjected to shearing stress there is produced a surface layer of a vitreous or amorphous character—a "flowed" surface—in which the particular ordered arrangement of the molecules or atoms which is characteristic of the crystalline matter largely disappears. Working at University College, London, Dr. Travers and Mr. R. C. Ray have recently obtained a very interesting confirmation of the Beilby Effect. The heats of solution (in kilogram calories per gram mol) of vitreous silica and silver sand (silica as crystalline quartz) in aqueous hydrofluoric acid were found to be 37·24 and 30·29 respectively. After grinding for fifteen hours the corresponding values were 36·95 and 32·46 respectively. If we assume that the internal energy of the amorphous phase produced by grinding is the same as that of the vitreous silica (silica glass), we can calculate from these results that about 31 per cent. of the crystalline silica has been converted by grinding into "amorphous" silica. The densities of silica glass and silver sand were found to be 2·208 and 2·638 respectively. After fifteen hours' grinding the density of the latter was lowered to 2·528. On the same assumption as before, it follows that about 26 per cent. of the quartz has been converted into the vitreous condition. The difference between the figures 31 and 26 is doubtless due to the approximate character of the assumption underlying the calculations and to experimental errors. There seems little doubt, however, about the soundness of the main conclusion—namely, that the mechanical action of shearing stress on crystalline matter is to produce a random molecular or atomic distribution in the surface layers.

This discussion, necessarily brief and limited, of certain aspects of the properties of surfaces—molecular orientation, surface concentration or adsorption, electrical or ionic polarisation—has dealt very largely with states of thermodynamic equilibrium. The chief interest of such studies has always appeared to me to lie in their possible ultimate bearing on the phenomena of life. We must remember, however, that the activities, and indeed the very existence, of a living organism depend on its continuous utilisation of an environment that is not in thermodynamic equilibrium. A living organism is a consumer and transformer of external free energy, and environmental equilibrium means non-activity, and eventual death.

It is probable, therefore, that along and across "living surfaces" there is a continual flux of activity. Does the very existence of these surfaces depend on some special sort of activity ? Questions such as these must make us cautious as regards any premature generalisation from simple physico-chemical results. But there is encouragement if we may assume that the physico-chemical manifestations of life are functions of the same powers and potentialities of electrons, atoms, ions, and molecules that we find in what we call inanimate environments. Life would then be simply a new functional relationship of very old parameters. at all events in so far as its various physico-chemical "mechanisms" are concerned.

In the totality of its activities and relationships, however, a living organism is an individual, and to arrive gradually at an understanding of this "individualisation" it will be necessary to study very carefully the laws pertaining to the intimate and particular modes of action of simpler individuals. The actions of an individual are conceived by science as determined by its internal state and by its relation to its environment. As we pass from certain peculiar atomic states, where the actions appear to have no relation to environment, to molecules, colloidal micelles, and living cells, the effects of the environment in determining activity seem to become more and more pronounced.

The internal state of a living cell or organism may arrive from time to time at "critical" points and "critical" transformations. Whatever may be the relation of such possible critical states to the previous cell-environment reactions the resulting events will be immediately determined by the special internal nature and activity of the cell itself. Is this "special internal nature and activity" simply a special type of organisation or arrangement of the positions, shapes, sizes, orientations and motions of electrons, atoms, ions, and molecules? To this oft-put question the answer of physico-chemical science is still in the affirmative. More complex individuals are not cloaked in any mysterious "law of complexity." Probably future progress will depend more on the investigation of the special nature, situation, and action of individuals than on the statistical thermodynamic treatment of the average behaviour of the "crowd."

THE BOHR ATOM AND THE PERIODIC LAW*

By N. V. SIDGWICK, D.Sc., F.R.S.

The essential peculiarity of the Bohr atomic model lies in the division of the successive groups of electrons into sub-groups. The electrons are rotating round the nucleus in orbits whose shapes are determined by the laws of ordinary dynamics (the electrostatic attraction of the nucleus being balanced by centrifugal force), but subject to the quantum restriction, which makes a certain set of orbits alone possible. Each orbit is defined by two quantum numbers, the first representing roughly the major and the second the minor axis of an ellipse; if the two are equal, the orbit is circular. Thus, if the principal quantum number of the group is, say, 3, the second may be 1, 2, or 3, giving three sub-groups 3_1 (long ellipse), 3_2 (ellipse) and 3_3 (circle). Hence a group of principal quantum number n can contain n sub-groups. The maximum number of electrons in a sub-group is found to be $2n$, though a smaller number may have considerable stability. Thus the maximum number of electrons possible in a group is $2n^2$ (2, 8, 18, 32).

The most stable arrangements of electrons are those of the inert gases :—

		1_1	2_1	2_2	3_1	3_2	3_3	4_1	4_2	4_3	4_4	5_1	5_2	5_3	6_1	6_2
Helium ..	2	2														
Neon	10	2	4	4												
Argon ..	18	2	4	4	4	4	–									
Krypton ..	36	2	4	4	6	6	6	4	4	–	–					
Xenon ..	54	2	4	4	6	6	6	6	6	6	–	4	4	–		
Emanation ..	86	2	4	4	6	6	6	8	8	8	8	6	6	6	4	4

It will be noticed that the largest groups are not on the outside, as in Langmuir's theory, but in the middle.

The development of these groups in the periodic table takes place in four different ways. (1) The establishment of two 1_1 orbits in H 1 and He 2. (2) The development of an 8-group (two fours) in the first short period (Li 3—Ne 10), repeated in the second short period (Na 11—A 18), in the second half of each of the two long periods (Cu 29—Kr 36 and Ag 47—Xe 54) and in the last quarter of the fifth period (Au 79—Em 86). (3) A third form of growth occurs in the first half of each of the two long periods, or rather just after their beginning (Sc 21—Ni 28 and Y 39—Pd 46) and in the third quarter of the fifth period, from about Hf 72 to Pt 78. In each of these places there are in the outer (valency) group of electrons two sub-groups of 4 expanding into three of 6; this involves 10 elements instead of 8, and so the single inert gas is replaced by the triad of Mendeléeff's eighth group. (4) The fourth type occurs in the rare-earth group (Ce 58—Lu 71), in which three sub-groups of 6 grow into four of 8, giving the 14 rare-earth metals.

The most general types of development are (2) and (3). (2) is that of the first two short periods, and is sufficiently familiar. Type (3) ($2\times4\longrightarrow3\times6$) occurring in the neighbourhood of the three triads, leads to quite a new series of properties. These elements all form metallic ions of variable valency, with marked colour and paramagnetic power, and they are all of high catalytic activity; moreover in the triads we find successive elements very similar to one another. All these properties are no doubt due to the same cause: that an arrangement of the outermost (valency) electrons in sixes has a less definite stability than an arrangement in fours, so that various groupings are possible which differ little in energy. Among the rare-earth metals (type 4) similar relations hold (small change of properties with increasing atomic number, colour, catalytic and paramagnetic power); but since the growth is that of an inner electronic group, the change in properties is still smaller, and for the same reason the absorption bands in the spectrum are far narrower than they are in the triads.

This is a very brief outline of the development of the periodic table on Prof. Bohr's theory. Of the almost innumerable relations between the structure and the behaviour of the elements which might be discussed, I will confine myself to one, which is not generally recognised, the relation between the atomic structure and the co-ordination number.

Combination between atoms involves a re-arrangement of their electrons with an increase of stability; and this can take place in two ways, either by the actual migration of an electron from one atom to another (ionic or polar link) or by the "sharing" of electrons (two to each link) between two atoms (non-polar link, covalency). This second kind of link, as Prof. G. N. Lewis, to whom its recognition is mainly due, has pointed out, is the only one which really deserves the name of link or bond; it is this alone which determines structure in the organic sense, as indicated by isomerism or stereoisomerism. How this sharing of electrons is effected is still uncertain. Each such electron certainly forms part of the constitution of both the atoms which it joins; and I have suggested that the electron encircles both nuclei. This point, however, I will not now discuss. I will only assume, what I think is beyond dispute, that a shared electron occupies an orbit of the same general type, but different from those of the unshared electrons.

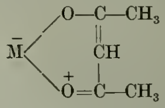
---

* Paper read before Section B (Chemistry) of the British Association on September 14.

Now the number of such non-polar links which an atom can form is primarily determined by the number of electrons which it can contribute to, or receive from, the atom to which it is linked; that is, by what we ordinarily term the valency. Sulphur, for example, with six valency electrons, can take up two methyl groups to make this number up to 8, as in argon. This limit, however, is not final. The sulphur can take up another methyl group (form a third covalency), if it expels an electron to make room for the new one, giving the positive $(CH_3)_3S$ ion. It can form a fourth covalent link, as in H_2SO_4, probably by itself contributing both of the electrons to two of links. Thus by a redistribution of electrons the atom can exert more than its normal number of covalencies. There is, however, a definite limit to the number which can be so exerted, and it is the nature of this limit which I propose to discuss. Those compounds in which the number of covalencies is larger than we should expect from the ordinary behaviour of the element really constitute the co-ordinated compounds of Werner. The stereoisomerism which many of them exhibit is a proof that the linkages are of the normal non-polar kind; the assumption of a special kind of subsidiary or co-ordination linkage is quite unnecessary.

An examination of these compounds shows that whilst an element may exhibit different co-ordination numbers, the maximum value of this number is definitely related to its position in the periodic table, that is, to its atomic structure, and in the following simple way. The maximum co-ordination number—the largest number of covalent links that the atom can form—is equal to the number of electrons in a sub-group of its valency electrons, or, in other words, to twice the principal quantum number of the group to which the valency electrons belong. In the first short period (Li 3—Ne 10) the valency electrons are in the 2-quantum group, for which the limit of a sub-group is 4. Here therefore the co-ordination number cannot exceed 4; this fact is generally admitted by the Werner school. In the second short period (Na 11—A 18), the valency electrons are in the 3-quantum group, and so a covalency of 6 is possible, as we see in $K_2[SiF_6]$ and SF_6. Indeed, this covalency is possible for any atom above neon. The 4-quantum group begins to be filled up after we have got past nickel, and though a co-ordination number of 8 is rare (the most conclusive example is OsF_8, b.pt. 47·5°) we find it as early as zirconium.

The best evidence for this conclusion is afforded by the acetylacetone compounds. These derivatives are formed by the replacement of the hydroxylic hydrogen in the enolic form $HO{\cdot}C(CH_3){=}CH{\cdot}CO{\cdot}CH_3$ (which may be abbreviated to HA) by the metal, which then joins itself to the ketonic oxygen by sharing two of the electrons of the latter. This gives rise to the grouping



each acetylacetone group forming two covalent links with the metal. Aluminium, for example, forms a volatile compound AlA_3, with a co-ordination number of 6. Boron, on the other hand, although trivalent, like aluminium, does not form BA_3 but a salt $[BA_2]X$ (X=anion). This shows that its covalency is limited to 4, its valency electrons being in the 2-quantum group, whilst that of aluminium, where they are in the 3-quantum group, can be 6. Again, whilst Si 14 and Ti 22, in which the 3-quantum group can contain the valency electrons, give 6-co-ordinated compounds $[SiA_3]X$ and $[TiA_3]X$, it is found that Zr 40, in which the 3-quantum group is already filled and the valency electrons are in the 4-quantum group, forms an 8-co-ordinated compound ZrA_4; and similarly we have CeA_4 and ThA_4.

This relation, that the maximum covalency or co-ordination number is equal to the number of electrons in a valency sub-group, is perhaps surprising. Since a covalency of n means the sharing on $2n$ electrons, we might have expected the highest covalency to be equal to half the number of electrons in a group (4, 9, 16) or half the number in a sub-group (2, 3, 4). The fact that it is equal to the number in a sub-group suggests that the pair of shared electrons forming one link occupy orbits with the same principal and different secondary quantum numbers: that the fully co-ordinated atom has two full sub-groups of shared electrons.

This may be made clearer if we calculate the "effective atomic number" of the atom in question, and resolve it, on the Bohr system, into the most probable groups and sub-groups. The effective atomic number is the actual number of electrons, shared or not, which are attached to the atom in the particular compound. It is attained by adding to the actual atomic number one for every substitution link and two for every link where the two electrons are taken from another atom (as in the link to the ketonic oxygen in the acetylacetone compounds), and allowing for electrons added or removed by ionisation. In the resolution the lines of the Bohr theory are followed as closely as possible. The following may be given as examples ; electrons of the same group are enclosed in brackets, and sub-groups of shared electrons are italicised :—

Al $= 13$ . . . : (2) (4,4) (3)
Al in $[\mathrm{Al}]\mathrm{Cl}_3 = 13 - 3 = 10$: (2) (4,4)
Al in $\mathrm{AlA}_3 = 13 + 3 \times 3 = 22$: (2) (4,4) (*6,6*)
S in $\mathrm{SF}_6 = 16 + 6 = 22$: (2) (4,4) (*6,6*)
Zr in $\mathrm{ZrA}_4 = 40 + 4 \times 3 = 52$: (2) (4,4) (6,6,6) (*8,8*) (4,4)
Co in $[\mathrm{Co(NH_3)_4Cl_2}]\mathrm{Cl} = 27 + 4 \times 2 + 2 - 1 = 36$
= (2) (4,4) (6,*6*,*6*) (4,4)

The relation between the nature of the symbol so obtained and the stability of the compound can only be elucidated by further investigation. In order to calculate the effective atomic number we must, of course, know the molecular weight of the compound and its ionisation, if any. It will be observed that the familiar octet is a phenomenon connected with the 4-co-ordinated compounds ; with covalencies of 6 or 8 it is replaced by a stable group of 12 or 16 electrons. This relation of the co-ordination number to the structure can only be accounted for by the Bohr theory, since the division into sub-groups on which it depends is one which that theory alone assumes.

I have not discussed the position of hydrogen, which must differ greatly from that of the other elements. The molecular weight of hydrofluoric acid, and the evidence for its ionisation into H^+ and F_2H^- have led Prof. Lewis to the formula H[F—H—F], in which the hydrogen exerts a covalency of 2, by sharing one of the " lone pairs " of a fluorine ion. This seems quite in accordance with the principles laid down above. The valency electron in hydrogen occupies a 1-quantum orbit. The group and the sub-group are here identical, their maximum size being 2, so that a covalency of 2 should be possible. The symbol for this divalent hydrogen atom would be $2 \times 1_1 + 2 \times 2_1$. The first quantum number would necessarily be different in the two pairs of orbits. But the behaviour of helium, in which one of the electrons may occupy either a 1_1 or a 2_1 orbit, would indicate that such a structure is not impossible. Fluorine, perhaps on account of its small atomic volume, is peculiarly able to develop the highest covalency of an atom, as we see in SF_6 and OsF_8. Also the only alternative structure for H_2F_2, which is $[H_2F]F$, on the analogy of $[(C_6H_5)_2I]I$, not only leads to a type of ionisation which is not in accordance with the facts, but also assumes a state of combination of the halogen which, though reasonably stable with iodine, is very unstable with bromine, and is scarcely if at all known with chlorine or fluorine. It does not of course follow that because hydrogen is in this sense divalent in its compound with fluorine, it is so in its compounds generally ; but it may be so in some cases.

Dyson Perrins Laboratory, Oxford

THE CONTINUOUS MEASUREMENT OF LARGE VOLUMES OF WATER

(FROM A CORRESPONDENT)

The recent paper, " The Storage and Handling of Water," read by Mr. J. B. Ball, of Kilmarnock, at the summer meeting of the Institution of Mechanical Engineers, included an interesting discussion on the scientific principles of the measuring of bulk supplies of water. When the water has a free surface and sufficient fall, the principle of the " V " or " Weir " notch is generally used. That is to say, the water is allowed to flow through a series of weirs or notches of known dimensions, placed side by side as may be required, a " V "-notch recorder being essentially an instrument for measuring continuously the height of the water flowing through the notch and recording this direct in gallons of water. The same principle is of course used in the chemical industry for boiler-feed water and, to a limited extent, in measuring, for example, acids, the " V " notch being of an antimony-lead alloy. A modern instrument for bulk water supply, such as the " Williamson " supplied by Messrs. Glenfield and Kennedy, Ltd., includes both a device for giving a continuous record in the form of a curve, by means of a pen and chart driven by clockwork, and an integrating mechanism to add up the figures. Further, the instrument when necessary is arranged in a duplex form so that a separate record can be kept of the compensation water, often always flowing from reservoirs.

When the water is flowing in very large pipes either the " Venturi " or the " Pitot " tube principle is adopted, and the latest development of the " Pitot " tube in this connexion is the " Cole " recording pitometer. The flow of the water is measured by means of a composite rod introduced into the pipe through a 1-in. stopcock. This rod contains the usual " Pitot " tube, a small tube bent with one end facing the flow and the other the reverse way, and the recording device is essentially a very delicate and sensitive differential pressure recorder graduated direct in gallons of water. The flow of the water in the pipe of course causes a difference in pressure in the tube circuit, the leg facing the stream having a slightly-increased pressure due to the action of the water, and the other leg a slight reduction because of a tendency to suction due to the water flowing away from the pipe. This difference of pressure is proportional to the velocity of the flow in the pipe—that is, the volume—and in this way an accurate record of any amount of water can be obtained.

The "Venturi" tube principle consists essentially of a constriction inside the pipe, one form of which is a simple hollow disc. Since the same volume of water is always flowing in the pipe at any one portion, the velocity through the disc is greater since the same bulk of water has to pass through less space. Consequently, a small pipe at the disc has a slightly greater pressure than one in the ordinary flow, and in the same way as in the "Pitot" tube this small difference of pressure is a measure of the amount of water flowing, this principle also being used in the metering of steam.

COMBUSTIBLE MATTER IN BOILER ASHES *

By W. S. PATTERSON, M.Sc., A.I.C.

The amount of combustible matter in the ashes discharged from boilers is often entirely neglected in the consideration of the boiler efficiency. When care is exercised it does not assume a large proportion of the total carbon consumed, but without attention strikingly large figures may be obtained, working under modern boiler conditions with artificial draught, moving grate, and mechanical stoking. This paper is intended to review briefly the extent and causes of such losses and to indicate methods of mitigation.

There are two ways by which combustible matter may be passed into the ashes. First, the coal ash may have a low fusion temperature and, attaining a semi-molten condition on the hearth, may absorb adjacent particles of coke, preventing further access of air and therefore combustion of such particles. Such carbon would be present embedded in the fused ash, and the discharge so formed is usually called clinker. The loss due to this cause is referred to as "fusibility loss" in this paper.

The second cause of the loss of carbon to the ashes is governed by mechanical effects produced on the grate. Under this heading is grouped losses due to irregular and too rapid movement of the grate, inadequate aeration of the fuel bed, and the use of fuel unsuited chemically and physically to the design of the grate. Such losses of combustible matter will be referred to as "mechanical losses," the carbon being present in the ashes as small pieces of free cinder, the average carbon content of these being about 90 per cent. in the samples reported.

It is shown later that in practically all cases the bulk of the carbon transferred to the ash discharge can be attributed to these "mechanical losses." To arrive at some general idea of the extent of the losses of combustible matter occurring in practice, samples of coal, together with the ashes formed from them, have been collected from several large boiler installations. Names and localities are omitted, but in all cases the conditions of combustion are those of mechanical stoking devices and grates and artificial draught. The samples were all taken during actual practice and are not special test samples. Table I gives the proximate analysis of the fuels, their calorific value, and the percentage of combustible matter in the ashes. Column 4 clearly shows the large variations in the amount of carbon lost in the ashes which occurs in practice.

TABLE I

Coal	Volatile matter 1	Fixed carbon 2	Ash 3	% Carbon in ashes 4	Carbon in ashes as % of coal 5	Calorific value of coal 6	Available calorific value 7	Size of coal 8
A	28·90	51·16	16·34	17·24	3·34	12,285	11,801	⅛in slack.
B	27·96	50·94	17·38	11·61	2·40	12,199	11,851	Dust to ½in. pieces.
C	25·38	50·54	18·88	22·84	5·50	11,826	11,029	Small slack.
D	24·98	52·68	20·38	13·22	3·00	12,107	11,672	¾in slack.
E	30·84	57·30	9·70	11·22	1·20	13,675	13,501	1in. slack.
F	24·86	47·60	25·40	30·44	11·00	11,254	9,659	Dust to ½in. pieces.
G	28·18	51·62	14·18	15·88	2·60	12,336	11,959	Clean pea slack.
H	26·00	46·36	23·68	17·64	5·00	10,788	10,063	½in. slack.
K	26·06	48·04	22·00	13·40	3·40	11,453	10,960	⅛in. slack.

Figures varying from 5 per cent. to 40 per cent. have been obtained. The weight of carbon lost in the ashes reckoned as a percentage of the original coal has been calculated from the carbon in the ashes. Thus, in case A, since the coal contains 16·34 per cent. ash and the discharge from the grate contains 17·24 per cent. carbon, $17{\cdot}24 \times 16{\cdot}34 \div 82{\cdot}76 = 3{\cdot}34$ per cent. of carbon in the ashes calculated on the coal. Table I, col. 5, gives these values. Taking the calorific value of carbon as 14,500 B.Th.U. per lb., deduction is then made of the available calorific value of the fuel reckoned on the actual carbon gasified. Taking case A again, we get 14,500×3·34÷100 =484 B.Th.U. as the heating value, lost in the ash discharge, per lb. of coal consumed. The available calorific value is therefore 12,285—484=11,801 B.Th.U. (*cf.* Table I, col. 7).

---

* Communication to the Yorkshire Section

In some cases the loss is very large and attention to the clinker discharge would result in a much improved combustion efficiency. To ascertain the relative proportion of the "fusibility losses" and the "mechanical losses" another set of experiments was carried out.

The figures for carbon in ashes given in Table I, col. 4, were the result of tests on the completely sampled ashes, and therefore include both "fusibility" and "mechanical" losses.

From each batch of ashes another laboratory sample was prepared by grinding up several large lumps of clinker. The combustible matter was obtained and calculated on the original ashes. Small particles of cinder representing "mechanical losses" were in this way eliminated and only the "fusibility losses" were determined. It was assumed that the cinder particles in the ashes contained 90 per cent. carbon, a figure confirmed by actual tests. The relative losses due to the two causes were then calculated as follows:—

In the case of sample A considering 100 parts of boiler ashes,

If X=amount of free cinder,
100—X=clinker.

$$\text{and } 2{\cdot}88\,(100-X)+90X=100\times17{\cdot}24$$
$$X=16{\cdot}3;$$

i.e., there are 16·3 parts free cinder (90 per cent. C.) and 83·7 parts clinker (2·88 per cent. C.) per 100 parts ashes discharged.

Hence, the actual amount of combustible matter lost in clinker per 100 parts ashes is 2·88×83·7÷100=2·41 per cent. By difference, the amount lost in the discharge by mechanical effects in the form of free cinder is 17·24—2·41= 14·83 per cent. The figures given in Table II, cols. 3 and 4, were obtained in this way.

TABLE II

Sample	% Carbon in clinker 1	% Carbon in completely sampled ashes 2	Carbon in clinker as % of total ashes 3	(2–3) carbon in cinder 4	Softening point temperature of coal ash °C. 5
A ..	2·88	17·24	2·41	14·83	1200
B ..	1·66	11·60	1·47	10·13	1260
C ..	0·65	22·84	0·48	22·36	1350
D ..	5·10	13·22	4·61	8·61	1130
E ..	1·30	11·22	1·15	10·07	1320
F ..	4·32	30·44	3·00	27·44	1140
G ..	0·50	15·88	0·41	15·47	1250
H ..	1·51	17·64	1·31	16·34	1290
K ..	2·82	13·40	2·37	11·03	1180

The results are interesting because they indicate what a large share of the loss of carbon can be attributed to what have been called "mechanical losses" (cols. 3 and 4).

The softening point of nine of the coal ash samples was determined (Table II, col. 5). There is distinct evidence of a relationship between the fusibility of the coal ash and the amount of unconsumed carbon in the clinker. Samples D, F and K show the highest content of carbon, and these are also the three ashes having the lowest softening temperatures; sample A is somewhat exceptional.

Considerable difficulty lies in the way of diminishing the loss of carbon due to fusibility of the ash. However, in all cases examined this quantity is only a relatively small proportion of the total loss.

The causes bringing about the more important "mechanical losses" can fortunately be eliminated by careful working and attention to the plant. Excessive grate speed is the first cause. Since the efficient combustion of any fuel has a time factor, loss of carbon must occur if the period during which the fuel is on the grate is not long enough to effect combustion under the conditions of the hearth. A higher rate of steaming may be produced by increasing the speed of the grate, but it may easily be obtained at the expense of producing a clinker containing 25 per cent. of combustible. The speed of the grate should be the minimum rate compatible with the maintenance of the steam pressure.

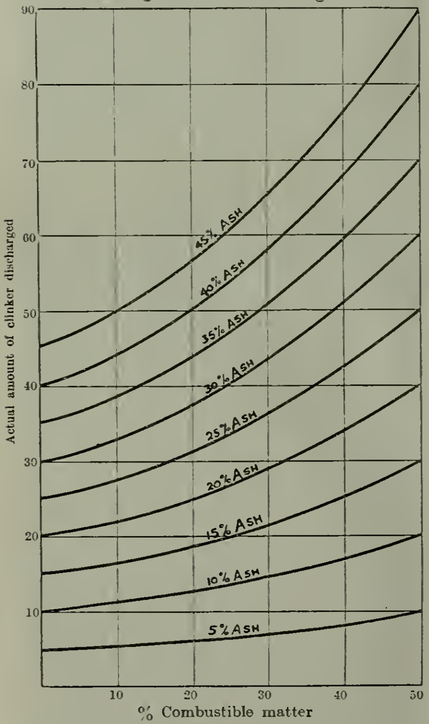
The next cause of the "mechanical losses" is the unsuitability of the design of the grate and the hearth for the fuels used. A fine slack cannot be burnt with efficiency on a grate designed for a large coal without some alteration being made. In one case 11·22 per cent. of combustible matter in the ashes was obtained from a plant when a clean 1-in. nut coal was used. The same plant, operating under similar conditions, produced an ash discharge containing 40·48 per cent. of combustible matter, when the fuel was a fine slack. This is perhaps an extreme case, but it serves to emphasise the importance of considering the suitability of the fuel to the conditions of the plant, as well as the calorific value and price when purchasing large supplies of coal.

The condition of the grate is also of importance in considering the amount of carbon lost to the ashes. A badly burnt grate owing to distortion will have gaps in it through which particles of cinder are riddled and also will have solid areas through which air cannot pass, and hence carbon on such areas will be transferred to the ash discharge. Frequent examination of mechanical grates is the best method of prevention here.

Adequate air supply through the incandescent fuel will always be an important factor in minimising loss of carbon to the ashes, since even with a perfect grate and slow speed of working, along with a suitable fuel, loss of carbon must result from insufficient air supply through the fuel bed. This cause is best eliminated by attention to the flue gases, and an intelligent interpretation of their composition.

It should be noted that for any given percentage of combustible matter in the ashes the actual loss of carbon calculated on the original coal becomes greater, with increasing amounts of ash in the fuel. Thus with 10 per cent. ash in the coal and 20 per cent. carbon in the discharge from the grate we get a loss of 2·5 per cent. of the carbon in the coal, whilst with 40 per cent. ash and still 20 per cent. combustible matter in the discharge, the loss of carbon becomes 10 per cent. The actual amount of discharge from the grate, in each of the above cases, per 100 tons of fuel consumed is 12·5 tons and 50 tons, respectively.

A graph is appended showing for different amounts of ash in the coal the relationship between the combustible matter in the ashes and the actual weight of ashes discharged.



Graph showing relation between carbon in ashes discharged, and the amount of the discharge for various percentages of ash in coal

Knowing the amount of ash in the coal used, and the weight of discharge obtained, the percentage of combustible matter in the ashes is obtainable.

The subject of the loss of carbon in ashes is of considerable importance now stoking operations are tending increasingly to become mechanical.

High thermal efficiencies in boiler practice cannot be obtained unless the fuels are chosen with consideration for the design of the hearth and grate and the conditions under which these must operate in practice. What might be called the combustion efficiency of the hearth with respect to any type of coal should have equal consideration in the purchase of fuel supplies, as the calorific value and price.

The author would like to acknowledge his indebtedness to Miss P. Ackroyd for much assistance in the preparation of samples and in the laboratory work.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS

The Society of Chemical Industry has in each of the past two years held a dinner in London in the month of October, but for the present year arrangements have been made for an Informal Dinner and a Social Gathering of Chemists under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, which members of these, and of any other of the Chemical Societies, with their friends (including ladies) may attend.

This dinner will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on the evening of Wednesday, October 31, at 7 for 7.30. The price of tickets for ladies or gentlemen will be 12s. 6d. each, not including wine.

Further particulars will be issued later, and the Councils hope that Members of the Societies mentioned, who intend to be present, will make early application for tickets, which must be limited to 300. These will be issued in the order in which applications accompanied by payment are received.

Applications should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

FORTHCOMING EVENT

Sept. 25. Society of Chemical Industry, *Birmingham and Midland Section.* Joint visit with the Midland Junior Gas Association to the Gas Exhibition at Bingley Hall, Birmingham. Meeting at 6 p.m. (1) "Specific Heat of Coal in Relation to its Composition," by G. Coles, B.Sc. (2) "A New Gas-Fired Combustion Furnace," by T. J. Hedley. (3) "Improvements in Nett Value Calorimetry, with a description of an automatic device for temperature and pressure correction," by C. H. Beasley.

INSTITUTE OF METALS

The Annual Autumn Meeting was held in Manchester on September 11 and 12. An interesting feature of the meeting was the formal opening by Sir George Beilby of the new metallurgical laboratory of the University of Manchester, in which accommodation is provided for up to 35 students and 10 research workers. The second Autumn Lecture was delivered by Lieut.-Col. Sir H. Fowler, K.B.E., who spoke on "The use of non-ferrous metals in engineering," and pointed out that it could be said that the use of non-ferrous metals by engineers was the ultimate object of all papers read before the Institute. Copper had been in long use, and alloyed with tin and zinc, its uses were as endless as were those of white metals. Aluminium was one of the most interesting metals, and recent investigations had opened up a new field for its use. Alloys of other metals were helping to solve the problems arising out of recent advances in engineering practice.

The following are summaries of the papers presented :—

(1) "The Cause of Red Stains on Sheet-glass," E. A. Bolton, M.Sc. After reviewing the various explanations of the cause of red stains, the author said that the stains occurred through reactions of copper oxides in the scale formed during annealing and the pickling medium. Cupric oxide, contrary to the usual opinion, was as harmful as cuprous oxide. Oxides of copper might be present owing to the action of acid left through careless washing after pickling, the presence of iron in the brass, and the use of impure rolling oils. The main cause was the use of the old-fashioned annealing furnace in which the flames impinge directly upon the brass. Possible remedies for the trouble were suggested.

(2) "Brinell Hardness Numbers," H. W. Brownsdon, M.Sc., Ph.D. The author drew attention to the desirability that Brinell numbers for non-ferrous metals should be expressed in figures that can be compared, and it was suggested that balls and loads should be used for which the ratio of the load in kilograms divided by the square of the ball diameter in millimetres was constant. Some one fixed ration should be invariably used for one class of alloys, *e.g.*, for copper alloys with Brinell hardness numbers from about 40 to 200 the choice should rest between the ratio 5 standardised in the United States or the ratio 10 favoured in this country.

(3) "Stereotyping," A. H. Mundey and G. Gartland, M.Sc. The evolution of stereotyping from its invention in 1750, by a practical metallurgist, W. Ged (an Edinburgh goldsmith), was traced from the plaster of Paris process to the use of papier-maché flong, and from the simple stereo plates for flat bed machines to the elaborate requirements of the modern newspaper.

(4) "The Crystallisation Effect on Galvanised Iron Sheets," J. D. Hannah, M.Sc., and E. L. Rhead, M.Sc. The authors have investigated the causes of failure to produce galvanised zinc surfaces having large characteristic spangles and state that the metal (iron or steel) had practically no influence on the result if the temperatures were satisfactorily maintained, that pure zinc did not yield the desired large spangles, and that too high temperatures led to the production of a zinc-iron compound which crystallised in needles on the metal and interfered with the development of the spangles. The presence of tin or aluminium did not produce the results, whereas the addition of zinc did so immediately. The effects obtained were ascribed to the separation of the impure zinc forming the layer on the metal sheet into conjugate solutions—lead-rich and zinc-rich—at the dipping temperature, and to the method of subsequent crystallisation. Bismuth introduced similar effects. The temperature at which good results could be obtained was limited by the tendency to form excessive amounts of the iron-zinc compound, and the time occupied in dipping and cooling.

(5) "Effects of Rate of Cooling on the Density and Composition of Metals and Alloys," R. C. Reader, Ph.D., M.Sc. The densities of pure metals were not affected by their rate of solidification, nor were those alloys which solidified at a constant temperature. With alloys that solidified over a range of temperature, the rate at which they passed through this range seriously affected the density, the slower the rate of solidification the lower being the density. Alloys possessing a long solidifying range were less dense in the centre than at the outside when prepared in cylindrical chill moulds. Rapid solidification greatly affected the composition of alloys that solidified over a range of temperature. When prepared in chill these alloys were richer on the outside in the component of the lower melting point and richer in the centre in the component of the higher melting point. Sand castings of these alloys were uniform. Alloys that solidified at constant temperature were uniform in composition throughout, whether prepared in sand or chill moulds.

(6) "The Effect of Small Quantities of Nickel upon High-Grade Bearing Metal," A. H. Mundey and C. C. Bissett, B.A., B.Sc., B.Met. A brief account was given of a practical trial of the effect of varying small quantities of nickel upon a tough well-reputed bearing metal, containing, per cenc., tin 93, antimony 3·5 and copper 3·5. Nickel was now added to this alloy, possibly as a means of identification though merit was also claimed for it. It was concluded from the results of physical tests that the beneficial results of nickel in an alloy of the character employed were yet to be demonstrated.

(7) "The Measure of the Change of Volume in Metals during Solidification," Hikozo Endo.

The paper contained the results of measurement of the change of volume during solidification or melting of a number of metals having low melting-points up to 1100° C. and forms the first report of the results of a long series of experiments which are to be extended to other metals having higher melting-points. The method of investigation consists in measuring the change of buoyancy of a metal suspended in an inactive liquid during its solidification or melting by means of a thermobalance.

(8) "The Constitution and Age-hardening of the Quaternary Alloys of Aluminium, Copper magnesium and Magnesium Silicide," Miss L. V. Gayler. The alloys dealt with contained up to 6 per cent. copper, 4 per cent. magnesium and 4 per cent. magnesium silicide, and it was shown that when these components were present in aluminium, any two of them had a marked effect on the solubility of the third, the sum of the effects being that ultimately $CuAl_2$ and Mg_2Si were both thrown out of solution. If copper and magnesium were present in a ratio greater than approximately 12 to 15, alloys quenched from high temperatures age-hardened at room temperature, whereas if the ratio of copper to magnesium were less than 12 to 5 no age-hardening took place, as there was little difference in the solubility of Mg_2Si at high and low temperatures. The slight increase in hardness obtained on further heat treatment of these quenched and aged alloys was due to the small difference in solubility of copper at the quenched and ageing temperature. The age-hardening of alloys of the Duralumin type was due primarily to Mg_2Si, copper causing very little age-hardening. The addition of magesium and copper was important as both reduced the solubility of Mg_2Si at high and low temperatures and subsequently reduced the maximum age-hardness due to Mg_2Si.

(9) "The Electrochemical Character of Corrosion," U. R. Evans, M.A. Experiments were described indicating that the corrosion of metals was mainly, probably entirely, electrochemical in character. Of the two main types, that accompanied by evolution of hydrogen gas was characteristic of reactive metals placed in acid solutions, but the velocity varied greatly with the degree of purity of the metal. Where this type was impossible, slower corrosion could occur at a rate determined by the diffusion of oxygen to the metal, and comparatively independent of the purity. When a metal was immersed in a solution of potassium chloride, one alkali was produced at the cathodic portions, the chloride of the metal was formed at the anodic portions, and hydroxide was precipitated where these meet. The electric current could be measured, and is found to account for the greater part of the corrosion observed. Generally the cathodic areas were those to which air had free access, whilst the anodic areas were those protected from aeration. Corrosion usually proceeded most rapidly at the comparatively "unaerated" places, hence the intense corrosion observed in "pits" and over areas covered up by porous corrosion-products.

(10) "Experiments with some Copper Wire; Cohesion a Function of both Temperature and Cold Work," D. H. Ingall, B.Sc. Five examples of copper wire were used representing soft annealed and four degrees of cold work given by 25, 40, 50 and 75 per cent. reduction of area by drawing. The cohesion at elevated temperatures was determined by placing given loads on the wire at atmospheric temperature, heating the wire and determining the temperature at which it broke. All the samples gave similar graphs (plotting cohesion against temperature), in which with rise of temperature the cohesion decreased along a straight line to a constant critical temperature of 350° C., beyond which the cohesion was represented by a sharply descending curve. The equations to the straight lines $C=a-bT$ and to the curves $TC^n=k$ (C=cohesion and T=temperature) showed that the percentage increase of the constant b and the percentage decrease of the constant n were represented by the corresponding percentage reductions for any given cold reduced wire.

(11) "Investigation of the Effects of Impurities on Copper," D. Hanson, D.Sc., C. B. Marryat, B.Sc., and Grace W. Ford, B.Sc. Studies of the effect of oxygen, up to a concentration of 0·36 per cent., on the mechanical and physical properties of pure copper, showed that oxygen had a relatively small effect on the properties of copper and was neither seriously deleterious nor remarkably beneficial. The mechanical properties were not much affected by small quantities of oxygen, nor was the electrical conductivity. The relatively small effect of oxygen was without doubt due to the fact that the solubility of the oxide in solid copper was so low that, for all practical purposes, oxygen could be regarded as insoluble in solid copper. The oxygen-bearing metals must, therefore, be considered as a heterogeneous mixture of pure copper and finely divided particles of cuprous oxide, and within the range of composition investigated the percentage of copper greatly exceeded that of cuprous oxide. The materials consisted essentially of a soft ductile copper matrix, in which harder particles of cuprous oxide were distributed, and the properties of the series were such as would be expected from a mechanical mixture of such constituents. These conclusions, however, were applicable strictly only to pure copper containing oxygen and free from other impurities. The effect of the simultaneous presence of other impurities might be very appreciable, and required special investigation.

(12) "Hardness Tests on Crystals of Aluminium." Hugh O'Neill, M.Met. Two pieces of aluminium strip were treated separately by the process worked out by Prof. Carpenter and Miss Elam, but only the first became a single crystal. By accident it was annealed for a

short time just below its melting point and upon its upper surface three series of parallel ridged markings were visible. X-ray examination showed that this surface was a rhombic-dodecahedral (011) face, whilst two crystals chosen from the second piece proved likewise to be presenting octahedral (111) and cube (001) faces respectively. Brinell tests showed that at low loads the different crystallographic planes resisted penetration to different degrees, and gave indentations of different shapes. In the Brinell sense the (110) face was the "hardest" and the cube (001) face appeared to be the "softest." But the load required to immerse the ball—and probably eventually to make it perforate the metal—was apparently the same in all cases. Crystal boundaries were also found to be without any appreciable effect in increasing the resistance of aluminium to penetration. In terms of Meyer's formula. $L=ad^n$, where L is the applied load and d the diameter of the indentation produced, *if a* 1 *mm. ball were used* then, whilst n varied from 2·483 for the (001) face to 2·274 for the (011) face, a was a constant for annealed aluminium. It was independent of the presence of grain boundaries and, in single crystals, of grain orientation.

(13) "The Behaviour of Metals under Compressive Stresses," H. I. Coe, M.Sc. Compression tests carried out on small cylinders of metals showed that with successive increments of loads plastic flow occurred, after the elastic limit had been exceeded, at an increasing rate. At a certain load the rate of flow for a given increment of load underwent a more or less abrupt change, very soft metals, such as tin and lead, becoming perfectly plastic, harder metals becoming more plastic than under preceding loads and immediately succeeding loads. When this particular load was expressed as a stress per sq. in. of the enlarged section of the cylinder, it was found that the value obtained agreed very closely with the maximum load per sq. in. in tension of the same material. The term "critical plasticity" was used to indicate the change in the rate of plastic deformation which most metals exhibited at a particular load. Annealed metals appeared to commence flowing at a comparatively low load and continued to do so at an increasing rate up to the load corresponding to critical plasticity; the same metals, however, in the worked condition were much more resistant to compressive stresses until they approached near the load corresponding to critical plasticity, when they suddenly collapsed and a marked temporary flow occurred.

(14) "A Dilatometric Study of the Transformations and Thermal Treatment of Light Alloys of Aluminium," Albert M. Portevin and Pierre Chevenard. Light aluminium alloys (density less than 3) capable of being hardened by quenching followed by tempering included the Duralumin group, whose essential characteristic was their magnesium content. The work of Rosenhain, Archbutt, Hanson and Gayler had linked up the phenomena of quenching shown by these alloys, with the variation of the solubility, in solid aluminium, of the compound Mg_2Si formed between magnesium and the silicon always present in commercial aluminium. But the solubility curves of this definite compound, Mg_2Si, in solid aluminium, had only been indirectly traced by the examination of alloys quenched at different temperatures, the transformations having hardly been studied, until last year, directly by direct physical measurements—in particular, by the investigation of thermal expansion. From their experimental work, the authors conclude that:—(1) The application of dilatometric methods, using the recording differential dilatometer, permitted the study of the transformations and the mechanism of heat-treatment of the light alloys of aluminium-magnesium-silicon, and in general of alloys containing two phase, univariant transformations. (2) The study of the constant temperature transformation by the differential dilatometer, using a high sensitivity apparatus, led to general expressions representing the phenomena as functions of time and temperature. (3) The phenomena of quenching and tempering in the aluminium-magnesium-silicon alloys could be interpreted by the known variations in the solubility of Mg_2Si in the solid state, without it being necessary to assume any further transformations in these alloys.

(15) "Equilibrium in the System Gold-zinc (based on Investigations of Electrical Conductivity at high temperatures)." Prof. P. Soldau. The alloys of gold and zinc belong to the type of AR-brasses, A and R being metals belonging to the first and second groups of the periodic system respectively. As in chemical nature these alloys were very close to the alloys of copper with zinc, *i.e.*, to the ordinary brasses, investigation of the nature of the alloys of gold and zinc should help to throw light on the complicated transformations which take place in the alloys of copper and zinc below their melting temperature. The author has thus investigated the alloys of gold and zinc, taking advantage of several different methods of physico-chemical analyses, that check and complement one another. Special attention was paid to the determination of electrical conductivity at high temperatures, which has necessitated the construction of a special apparatus. To check this, it was used for the determination of the transformation temperatures in iron and steel, which have been accurately determined by various physico-chemical methods. When the results obtained by the electrical conductivity method at high temperatures and by quenching showed a complete concordance, then that former method could be recommended for the investigation of other metallic systems.

ACADÉMIE DES SCIENCES

Monsieur Lacroix, the perpetual secretary of the Académie, gave an interesting account, at the meeting held on August 27, of a meteorite found in the Haut Garonne district, and containing the rare mineral aldhanite (calcium sulphide).

On September 3, Monsieur Joubin communicated the results of experiments made by Mme. Randoin on the food value of the oyster. The author claimed that the oyster possessed the highest known content of vitamin C, only the lemon being comparable with it in this respect. Using guineapigs affected with scurvy, it was found that 15 g. of oysters given in summer contained sufficient vitamin C to prevent the occurrence of the disease, a smaller amount being necessary in winter. This large content of vitamin was correlated with the food ingested by the mollusc. During the same meeting, note was taken of a brochure by Monsieur M. Delacre entitled, "An Essay on Chemical Philosophy."

On September 10, Monsieur J. L. Breton gave an account of an interesting article by Prof. Cotton on "The Magnetic Saturation of Iron." Monsieur Breton also presented a note by Monsieur P. Dumanois on a new process for dehydrating air, a process which has become necessary owing to the storage of large quantities of absolute alcohol or mixtures of alcohol and petrol used as motor fuel. If special precautions are not taken, the presence of moist air may cause either diminution in the concentration of the alcohol, or effect the stability of the mixture. The device consists in passing the air through a small tank provided with baffles and containing alcohol which absorbs moisture from the air. An automatic control is provided to ensure a constant level of alcohol in the tank.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on September 13, 1923. In the absence of the chairman and vice-chairman, Sir John Brunner, Bart., occupied the chair. Before commencing the business of the day sympathetic reference was made to the death of Dr. E. K. Muspratt, and it was resolved to send a letter expressing the condolences of the Council to Sir Max Muspratt, Bart.

It was decided that the Association should tender evideuce before the Committee, which had been set up by the Minister of Health, to consider and report upon the use of preservatives and colouring matters in food.

The industry is very interested in publicity, and in order that the public may be kept informed, the Council authorised the General Manager to proceed with the preparation of two films illustrative of the distillation of coal, and of the heavy chemical industry.

The provisions of the Smoke Abatement Bill, 1923, were examined, and whilst the new Bill is a little more favourable than that introduced into the last Parliament there are still several matters which require adjusting from the standpoint of the Chemical Industry. The General Manager was instructed to secure amendments that will safeguard the position.

The General Manager reported that the plans for the Chemical Section of the British Empire Exhibition are now complete and the whole of the available space has been allocated. The Scientific Section is making great headway under the guidance of Dr. H. Levinstein, and it is expected this Section will prove of great interest to the general public.

It was decided to hold the next annual meeting of the Association within the precincts of the Exhibition on Thursday, July 10, 1924.

Sir William Alexander presented a very interesting report on the Ruhr situation, which showed that the occupation by the Franco-Belgian forces had not had the effects anticipated in some quarters of bringing the German dyestuff industry to a standstill.

Amongst other matters of routine which were dealt with was the election of the Cwmbran Chemical Co., Ltd., to membership of the Association.

PERSONALIA

Mr. C. W. Heppenstall has been elected chairman of the advisory board of Pittsburgh business and scientific men organised to cooperate with the work of the Department of Mining and Metallurgy of the Carnegie Institute of Technology.

Prof. C. Matignon, vice-president of the Société de Chimie Industrielle has been appointed an Officer of the Legion of Honour.

F. W. Zerban has succeeded C. A. Browne as chemist in charge of the New York Sugar Trade Laboratory.

Prof. N. Parravano has succeeded Prof. Paternò as director of the Chemical Institute of the University of Rome.

Prof. Raffaello Nasini has been elected president of the Italian Association for General and Applied Chemistry for the period 1923-25.

On September 2, Wilhelm Ostwald, the well-known physical chemist, celebrated his seventieth birthday at his residence, "Energie" in Grossbothen, near Leipzig.

Prof. J. Franck, who succeeded Prof. Debyes at Göttingen, has been offered the chair of physics in Berlin University, vacant through the death of Prof. H. Rubens.

* * *

From France, the death is announced of F. Magonnier, managing director of the Société des Usines de St. Gobain.

A VISIT TO THE ENGINEERING EXHIBITION

By Prof. J. W. HINCHLEY, A.R.S.M., Wh.Sc. M.I.Chem.E.

(*Continued*)

Another useful exhibit is the "Arca" automatic regulator shown in operation for controlling the hygrometric state of the air, the temperature, vacuum or pressure in a vessel, or the electrical conditions at any point. A diaphragm valve controlling the admission of water to the operating cylinder which moves the valve admitting the supply of motive fluid (water, steam, gas, etc.) is actuated by water, which also passes through a jet impinging on the end of a lever whose position is determined by a pressure box in the case of a motive fluid, by a series of cotton threads where the hygrometric state is to be controlled, by an ebonite strip for air temperature regulation or by other devices to suit the conditions in question. The lever moves only about one-thousandth of an inch, yet the action is most definite and the regulation most remarkable.

The Cambridge and Paul Scientific Instrument Co., Ltd., exhibit a range of their well known instruments. The Foster Instrument Co., Ltd., show a robust form of electrical indicator and a strain-meter for measuring changes in the strain of a structure due to loading, heating or other forces.

A large number of pumps are exhibited, several being shown at work. The water elevator of Messrs. Boulton and Paul, Ltd., claims one's attention on entering the exhibition, for it is at once seen lifting water through a height of 40 feet. It consists of a cellular endless belt hanging in the water to be lifted and passing over an upper driving pulley. The belt is made by rivetting a zig-zag strip of zinc on the back of an ordinary machine belt. The cells formed carry the water and discharge it as the belt turns round the upper pulley. The apparatus will lift water through a distance of over 300 feet at a high efficiency, and quantities up to 20,000 gallons per hour can be dealt with.

Rotary pumps of different kinds are shown by several exhibitors. The "Squeegee" pump is shown at work by the Avonmore Pump Co., Ltd.; the "Kitson-Utley" by the Kitson Engineering Co., Ltd.; the "Feuerheerd" by Messrs. Stothert & Pitt., Ltd.; and the "Essex" by Messrs. Jobson & Beckwith, Ltd. A new design of hand or power piston pump is shown by Messrs. Zwicky, Ltd. It has valuable features with respect to a filtering device and the simple mechanical arrangements of the valves, gland and other parts.

Welding apparatus of all kinds are shown in operation at several stands. Oxygen sheet-metal cutting plant by several makers may also be seen.

Metallisation, Ltd., demonstrate the "Schoop" process of coating surfaces with lead, copper, tin, zinc, etc. The coating metal, in the form of a wire, is melted by an oxy-hydrogen or other flame and projected by a "pistol" on the surface to be covered. Vessels coated with lead, copper, tin and zinc may be inspected. The thickness of one coating appears to be of the order of 1/100th inch. The artistic results of spraying decorative ironwork with copper, brass, zinc, etc., are very delightful.

The Radio-jet air pump, shown by Messrs. John Musgrave & Sons, Ltd., will attract chemists engaged in distillation work who demand "more and more vacuum." Although the plant shown is intended for marine service, it can be readily adapted for distillation under vacuum.

Air and gas compressors are to be found at many stands. An important exhibit is that of Messrs. Luchard & Co. Low, medium and high-pressure machines are shown, the last up to 7000 lb. per sq. in., of which the compactness and workmanship are admirable. The British Oxygen Co., Ltd., and Messrs. Lacy-Hulbert and Co., Ltd., also show some excellent machines. Several types are shown at work on refrigerating plants by Messrs. John Kirkaldy, Ltd., Messrs. L. Sterne & Co., Ltd., Apeldoornache Machinefabriek, Messrs. West & Beynon, Ltd., and the Kitson Engineering Co., Ltd.

The castings shown by Messrs. Thomas Summerson & Sons, Ltd., deserve close inspection, and chemical engineers should investigate the value of their high tensile "Granfin" cast iron. It is an electric furnace product, free from impurities, and, apart from its simple use, should form a basis for chemical cast irons of great value to the chemical industry.

The Yorkshire Copper Works, Ltd., and Messrs. Allen Everitt & Sons, Ltd., exhibit tubes for condensers and evaporators of copper, brass and special alloys.

"Plymax" is ordinary plywood having a thin sheet of galvanised steel cemented on each side, exhibited by Messrs. Venesta, Ltd. It can be cut by saws and formed by means of corner-pieces, etc., into skips, trucks, barrels, tanks, etc. It ought to be of great value to chemical manufacturers.

It is impossible to avoid the stand of the "Stream Line Filter Co.," or to avoid discussion of the remarkable results obtained. A large filter with a capacity of 10,000 gals. per hour is seen in the centre of the stand, and eight smaller filters are at work on the stand itself. Still smaller laboratory filters are used for demonstration, and working models show the action of the cleaning plugs, which force out the separated solids. One small filter is at work on cyanide sludge, yielding a stiff residue and a clear filtrate. Two others remove dye from solutions, and another filters beer and produces a colourless liquid which is not beer and does not smell like beer, or produces any other filtrate up to a bright beer which is really beer. The concentration of soluble substances of which there is evidence may be due to the stream-line action rather than to edge filtration. At any rate, the filter will produce a profound change in nearly all industrial undertakings. The machine is welcome, however, to the chemical engineer and manufacturer as a means of dealing with problems which are becoming day by day more and more overwhelming.

It is curious to note that the straining apparatus exhibited by Auto-Klean Strainers, Ltd., has a remarkable resemblance to Dr. Hele-Shaw's apparatus. Metal sheets with separating washers are employed, and although straining only is accomplished, the advantages over gauze strainers are well made out.

Another device due to Dr. Hele-Shaw, a flexible joint for piping, is shown by the Victualic Co., Ltd.; the force to be resisted, the pressure in the piping, makes the joint by means of a flexible ring acting like the "U" leather in hydraulic plant. A joint based on the same principle, the "Flexstel," is shown by Messrs. W. H. Dorman and Co., Ltd. Klinger Patents exhibit a valve which has some relationship to these joints. It is a seatless valve in which closing is effected by a cylindrical metallic plunger moving through two jointing rings of flexible material separated by a metallic bush in which are the ports for the passage of the fluid.

Centrifugal separators of excellent workmanship and design are shown by British Separators, Ltd., the De Laval Chadburn Co., Ltd., and by United Water Softeners, Ltd. (the Sharples' machine). The value of these machines for separation work is well known.

For the slow drives required in many types of chemical plant the "H. R." reduction gear shown by the H. R. Gear Co., Ltd., is very attractive. It is an arrangement of worm gearing in an extremely small casing, by which reductions of 100,000 to 1 in its simple form and of 10,000,000 to 1 in the compound form, may be readily obtained. The workmanship and efficiency of the gear are everything that could be desired.

The joinery machinery shown by the Eland Engineering Co. also deserves some notice. A simple lathe and circular saw are mounted together and adapted to form woodwork joints for frameworks; a cylindrical projection and recess is formed and is held together by a screw; the joint replaces the usual costly mortice and tenon.

It is difficult to mention in a short space all the interesting exhibits, but a slide-rule reading to four figures, the "Otis-King Calculator," ought not to be omitted. This is a tubular slide-rule with spiral scales on one tube, with a plain tubular cursor; it is equivalent to a slide-rule of ordinary type, 66 ins. long.

CORRESPONDENCE

THE ATOMIC THEORY AND THE PROGRESS OF CHEMISTRY

SIR,—In January last I heard Sir J. J. Thomson make a statement almost, if not quite, identical with that reported in your editorial of September 7. I was startled, and pondered the matter for some time, finally concluding, on the following grounds, that the statement is too severe a condemnation of the chemistry of the last century. The atomic theory as originated by Dalton and subsequently developed by the application of Avogadro's hypothesis is the basis of the formulæ and equations which have allowed chemists of the last 100 years to develop the synthetic methods that have been so important in both pure and applied chemistry. No one now doubts the truth and the importance of Avogadro's hypothesis, as is evidenced by the publication of the fifth edition of Nernst on "Theoretical Chemistry from the Standpoint of Avogadro's Rule and Thermodynamics." Yet it is hard to see what meaning such a rule could have, apart from an atomic theory.

At the same time I should like to point out that he suggests, even urges, that in the teaching of chemistry the structure of the atom should be the starting point and that it should be brought forward to explain the phenomena of the science from the first. So here is another matter for consideration: will it pay to teach chemistry upside down?—I am, Sir, etc.,

E. PASCAL

Bishop's Stortford College Sept. 12, 1923

THE BRITISH DYESTUFFS INDUSTRY

SIR,—May I be allowed to make the following comments on Prof. Morgan's article on the British Dyestuffs Industry, which appeared in the last issue of *Chemistry and Industry*.

1. Read Holliday and Sons, Ltd., was not in low water financially, but had paid 10 per cent. on its capital for several years. Its management was responsible for dinitrochlorobenzol being available in this country at the outbreak of war, from which so much lyddite was subsequently made.

2. The tragedy of the present dyestuffs industry is that the two men who had long commercial and technical pre-war experience of the industry, have been allowed by directors, without any of this experience, to leave the industry. I refer to Dr. Levinstein and Sir Joseph Turner.

3. Patent Blue at 8s. is 6½ times pre-war price: the direct cotton colour (Sky Blue FF) at 12s. 3d. is twelve times its pre-war price. If prices on this basis are essential to maintain the industry as a national necessity, the colour-user's argument is that the whole burden should not be borne by him. The Government's share in a national necessity is £1,700,000 share capital largely inflated at the formation of the British Dyestuffs Corporation.

4. The present Board of the Corporation has neither technical qualifications nor pre-war commercial experience of the industry. Is it to be wondered at that a Board so constituted cannot live up to a three-times factor.—I am, Sir, etc., C. M. Whittaker

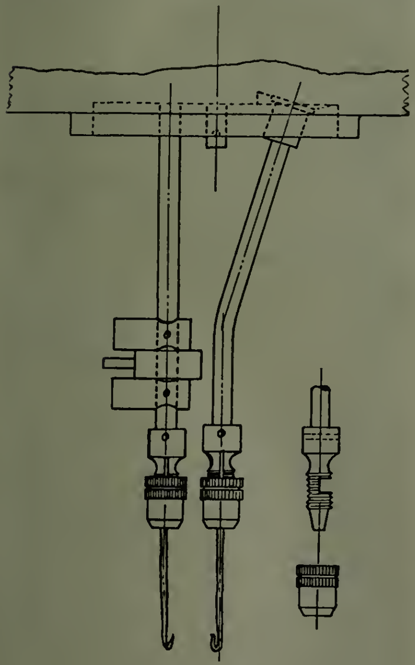
Cheadle Hulme, Cheshire

ELECTRICAL CONTACTS FOR THE BOMB CALORIMETER

Sir,—I have used the bomb calorimeter for a number of years and appreciate the great accuracy of the results obtained thereby, but have always had difficulty in obtaining a suitable adjustment for the electrical contacts, owing to the rapid corrosion of the points. After experimenting with several devices, with more or less success, I have now found that the one shown in the accompanying illustration is most satisfactory, and send it you for publication in the hope that others may find it equally successful.



Screw Adjustments for Bomb Calorimeter

By means of the screw adjustment shown, the terminals may be removed for cleaning or, if and when beyond this stage, replaced by new ones.—I am, Sir, etc., James S. Mann

Langdon Hills, Sept. 11, 1923

THE FINISH OF CHEMICAL GLASSWARE

Sir,—It is an easy matter for those chemists who have access to a power-driven grindstone to grind off at an angle the stems of separating and dropping funnels, condenser inner tubes, etc.

Not all chemists, however, are so fortunately situated, and I venture to suggest to the manufacturers of chemical glassware that the ends of such apparatus should be ground in this way as a matter of standard practice in manufacture. At present it is quite common, for example, to find a condenser inner tube practically full of liquid when it is used in the reflux position, owing to the fact that the end of the tube is drawn off so much that it prevents the return of liquid to the flask and the passage of vapour at the same time.—I am, Sir, etc.,

THE ORIGIN OF SYMBOLS

Sir,—Your correspondent " Analyst " desires information on the earliest use of symbols in chemistry.

We all know that our alchymistic predecessors used symbols for expressing their ideas and sometimes for hiding their ignorance. However, up to the time of George Wilson, Chymist, each man was a law unto himself. Wilson (c. 1670) held a strict inquiry into the possibility of transmutation, and in each case seems to have co-ordinated the symbols of the varied inventors into standard forms. It is probable that through Wilson's work the pharmaceutical symbols for the drop, drachm, scruple, ounce, pint, etc., were fixed and made eternal.

As chemistry ceased to be an art and became a science these symbols became obsolete, until Dalton on August 26, 1804, used a new set of symbols to explain his atomic theory to Thomas Thomson. Dalton's symbols were simply circles oriented internally to represent a few elements.

It is strange now to remember that Davy held the atomic theory up to ridicule, but was convinced by Mr. Gilbert, who owed his conversion to Dr. Wollaston. Now Dr. Wollaston for argument substituted " Proportion " for " Atom," and shortly afterwards he put out a sliding rule, or rather a set of slide rules, whereby the " Combining proportion of a substance in any weight whatever " could be seen at once. The present writer's great grandfather received an early ivory set of these slide rules with written instructions from Dr. Wollaston, and the writer remembers them being destroyed by the breakage of a winchester of Liq. Potassae. The scales were all provided with symbols in the modern sense : Oxygen, O=unity. Hydrogen, H, was 1/7 ; Nitrogen (Azote) was given as Az, Sodium or Soda as Na, Potass. as Ka, and quite a number of others. The atomic weights even when taken as equivalents were in most cases rather incorrect, but I am of opinion, partly on hearsay evidence from my father, and partly on the contemporary account of Thomson, that the real founder of our chemical symbols and perhaps of volumetric analysis was Dr. Wollaston, and that both subjects came from his slide rule.

I do not know of another of those rules, although an account of a later one much more complete is given in *Phil. Trans.*, 1814, to which unfortunately I have not access. It is rather curious that in the old days men like Boyle, Black and Cullen, who really had something to say, used no symbols, whereas the visionary alchymist and the charlatan held out unintelligible formulae as being proofs of their theories. Is history a cyclic phenomenon ?—I am, Sir, etc., N. C. L.

Paisley

THE STREAM-LINE FILTER

Sir,—I am writing with reference to the description in the editorial of the issue of September 7 of the capabilities of Prof. Hele-Shaw's stream-line filter. The statement there appears that substances in solution (dyestuffs, common salt, copper sulphate, etc.) may be partially "filtered" off.

While not doubting that the solution which emerges is more dilute than the original solution, I make bold to criticise the use of the term "filtered" in this connexion. If we say that some of the solute has been filtered off in the ordinary sense of the word, we make the entirely unjustifiable assumption that the molecules or ions of the solute are larger than those of water.

The phenomenon of the removal of part or all of a solute by such a process is by no means a new one. It may be illustrated with much simpler apparatus than Prof. Hele-Shaw's filter. If a glass tube is packed with glass wool or asbestos and a coloured solution poured through it, it will emerge colourless or, at least, much paler in colour.

The explanation of this was provided by Prof. Sir J. J. Thomson to explain the action of semi-permeable membranes in observations of osmotic pressure. (The action of these membranes is similar in that they allow free passage of the solvent molecules but impede those of the solute.)

This explanation is as follows : The tendency of a liquid is always to diminish its surface energy wherever possible. In most cases, the effect of increasing the concentration of a solution is to diminish the surface tension with a solid surface. Now, suppose we have a solution flowing through a very narrow channel. In order to diminish its surface energy, the solute will tend to accumulate at the sides, and if the channel is long compared with its diameter the solute will be partially or completely removed from the emerging liquid.

I have no doubt that Prof. Hele-Shaw's filter is a perfectly parallel case to the above, and suggest that this explanation of its action is a perfectly satisfactory one.—I am, Sir, etc.

NEWS AND NOTES

CANADA

Mineral Output in 1921

The following figures showing the mineral production in 1921 have been extracted from the annual report published by the Dominion Bureau of Statistics, Mining, Metallurgical and Chemical Branch :—

Metallic :—	1921	Quantity	Dec. (−) or Inc. (+) per cent.
Cobalt, metallic and contained in oxide	Lb.	251,986	—53·85
Copper	,,	47,620,820	—41·64
Gold	Fine oz.	926,329	+21·09
Iron pig from Canadian ore	Tons	56,564	—25·45
Iron ore sold for export	,,	1,058	—88·09
Lead	Lb.	66,679,592	+85·46
Nickel	,,	19,293,060	—68·55
Palladium	Crude oz.	591	—35·27
Platinum	,,	292	—50·92
Rhodium, osmium, iridium	,,	57	—88·89
Silver	Fine oz.	13,543,198	+1·60
Zinc	Lb.	53,089,356	+33·18
Non-metallic :—			
Actinolite	Tons	78	—22·00
Arsenic, white and in ore	,,	1,491	—39·37
Asbestos	,,	92,761	—53·52
Barytes	,,	270	—64·05
Chromite	,,	2,798	—74·60
Coal	,,	15,057,498	—9·47
Corundum	,,	403	+105·61
Feldspar	,,	29,868	—21·14
Fluorspar	,,	5,519	—50·88
Graphite	,,	937	—57·21
Gypsum	,,	386,550	—9·93
Magnesite	,,	3,730	—79·70
Magnesium sulphate	,,	2,029	+4·21
Manganese	,,	68	—89·52
Mica	,,	702	—68·13
Natro-alunite	,,	30	—
Natural gas	M. cu. ft.	14,077,601	—16·43
Oxides, iron	Tons	9,048	—52·70
Peat	,,	1,666	—63·38
Petroleum, crude	Bbl.	187,540	—4·44
Phosphate	Tons	30	—
Pyrites	,,	32,173	—24·36
Quartz	,,	100,350	—21·78
Salt	,,	164,658	—21·54
Sodium carbonate	,,	197	—
Sodium sulphate	,,	623	—23·18
Strontium	..	—	—
Talc	,,	10,124	—53·28
Tripolite	,,	341	+31·15

The total value of the mineral output was $171,923,342, of which metallic minerals represented 28·7 and non-metallic minerals 51·09 per cent. The two biggest items were gold and coal, representing 11·14 and 42·14 per cent., respectively, of the value of the total output. This total value includes $34,737,428 for the production of structural materials and clay products, the chief items being 2931 tons of fire-clay and 124 t. of kaolin and 5,752,885 barrels of cement.

FRANCE

The Coke Industry

During May, the French coke works belonging to the French coal companies produced, roughly, 160,000 metric tons of coke, compared with 250,000 t. during the same period before the war. Several coke works have been restarted in the Nord District, and others are in such a state of preparation that it is hoped that 140,000 t. a month will be produced at the end of the year in the Nord and Pas de Calais districts alone, or, roughly, 200,000 tons in the whole of France, 120,000 t. being destined for use in blast furnaces (in May, 180,000 t. was used for this purpose). It is estimated, though not on a sure basis, that the coke production of the metallurgical companies amounts to some 120,000 t. per month. In the metallurgical industry many extensions are taking place, and one company alone, the Compagnie des Forges et Acièries de la Marine et Hornecourt will put up a battery of 70 by-product ovens at the end of the year, when the production of coke by the metallurgical industry should probably reach 150,000 t. per month. Altogether it can be estimated that by the end of the year the production of metallurgical coke will have reached 3,200,000 t., compared with 4,000,000 t. in 1914. The actual tendency is to install batteries of 70 coke ovens at a cost of, roughly, 10,000,000 francs and with a capacity of up to 160,000 t. per annum. In 1922 the French consumption of metallurgical coke was 6½ million t., compared with 7 million t. in 1913, 4 millions of this being produced locally and the rest imported. The actual deficit is thus, roughly, 2,000,000 t. per annum.

UNITED STATES

Asbestos in 1921

The asbestos-mining industry in the United States showed a great falling off in 1921, and by the end of the year production had almost ceased. The asbestos sold in 1921 declined about 50 per cent. in both quantity and value below that marketed in 1920. Chrysotile, however, which formed 93 per cent. of the total value, declined 65 per cent. in quantity and 53 per cent. in value. Asbestos was mined in Arizona, California, Georgia, Idaho, and Maryland, making a total of 831 short t. valued at $336,968. The unmanufactured asbestos imported from Canada in 1921 amounted to 71,412 t., valued at $2,687,439. The total general imports amounted to 72,463 t., valued at $2,948,302, as compared with 167,558 t., valued at $9,120,253 in 1920. This was a decrease of 57 per cent. in quantity and 68 per cent. in value.

The total world's production of asbestos in 1921 was 106,500 m.t., being the smallest since 1914. The outstanding features for 1921 are the great decline in the Canadian output of asbestos (82,015 m.t.), which is about half the quantity for 1920 (162,037 m.t.); also the maintenance of the Rhodesian production, which is mostly chrysotile (*cf. J.*, 1921, 254 R.).—(*U.S. Geol. Surv., Sept.* 19, 1922.)

Fuller's Earth in 1921

The activity prevailing in recent years in the fuller's earth industry was checked in 1921 by depression in the petroleum industry, the output of fuller's earth in that year declining by 18 per cent. in quantity and 21 per cent. in value to 105,603 short tons valued at $1,973,848. According to the U.S. Geological Survey, Florida produced 54 per cent. of the total output, 99 per cent. of the output coming from Florida, Georgia, and Texas. The demand for fuller's earth increased late in 1921 and the outlook for 1922 was so good that new deposits were to be developed in Georgia and Pennsylvania. Imports, which had increased in 1919 and 1920, fell off in 1921, reaching the lowest quantity since 1900, and representing only 39 per cent. of the export in the record year 1914. The imports included 9261 short t. of wrought or manufactured fuller's earth and 483 t. of unwrought or unmanufactured fuller's earth, the total value being $119,415.—(*Cf. J.*, 1922, 158 R.)

GENERAL

Tin in 1921

The Imperial Mineral Resources Bureau has now issued a further publication belonging to the series on the Mineral Industry of the British Empire and Foreign Countries, devoted in this case to statistics of the production of, and trade in, tin. From it we extract the following figures showing the world's production of tin ore in terms of metal and the world's smelter production of tin in 1921 :—

	Output of Tin Ore Long tons	Smelter Output of Tin Long tons
United Kingdom ..	679	14,000
Nigeria	5,057	—
Swaziland	234	—
Union of South Africa	720	—
Southern Rhodesia ..	—	4
India	1,362	172
Straits Settlements ..	*	41,917
Federated Malay States	34,490	—
Unfederated Malay States	1,611	—
Australia	2,650	2,985
Bolivia	18,804	60
Germany	—	4,000†
United States	—	10,305
China	11,200	6,134
Siam	6,181	—
Dutch East Indies ..	26,911	—
Other Countries ..	900	500
	110,800	95,000

The pamphlet (pp. iv+44) can be obtained from H.M. Stationery Office, price 1s. 6d.

REVIEWS

Practical Physical Chemistry. *By* Alexander Findlay, M.A., D.Sc. *Fourth edition, revised and enlarged. Pp. xvi*+298. *London: Longmans, Green and Co.*, 1923. *Price* 7*s.* 6*d.*

Five successive impressions of Findlay's Practical Physical Chemistry have been issued by the publishers since 1914, when the third edition first appeared. This fact affords very striking evidence of the greatly increased attention which has been given in recent years to the experimental side of physical chemistry in University courses of instruction. In meeting the demand for a fourth edition, the author has taken the opportunity to revise the text and to introduce a certain amount of new matter dealing with forms of apparatus and types of measurement with which all chemical students should have some acquaintance.

In the chapter on optical measurements, descriptions are given of the Abbe refractometer and of the Hilger wave-length spectrometer. In the section on molecular weights, an account of the boiling-point apparatus designed by Cottrell has been included. In actual practice Cottrell's apparatus has been found to give more satisfactory results than can be ordinarily obtained with other forms of ebullioscopic apparatus, in that fluctuations of temperature and errors of determination due to superheating—familiar causes of trouble to most students who have had experience of ebullioscopic work—are very largely avoided.

In the chapter on electromotive forces, sections have been added which deal with oxidation and reduction potentials, and with the methods of electrometric analysis, including the determination of hydrogen-ion concentration. The very frequent use of p_H as a means of expressing the hydrogen-ion concentration of a solution, renders it important that the beginner should realise as clearly as possible the significance of this quantity. The statement that "p_h or pH has been introduced as a symbol for the expression $-\log_{10}h$," where h is the hydrogen-ion concentration (p. 218, footnote 2), can scarcely be regarded as a satisfactory definition. Its physical significance is much more likely to be appreciated if p_H is defined as the logarithm of the number of litres of solution which contain one gram of hydrogen-ion.

The field of colloid chemistry is brought to the notice of the student by the introduction of a few appropriately selected exercises, which serve to illustrate some of the chief characteristics of matter in the colloidal state.

In accordance with the author's desire to preserve the character of the book as a guide through a general course of practical physical chemistry, the bulk of the volume has not been much increased by the revision. Whilst there is much to be said for this conservative policy, it should not be allowed to interfere unduly with the introduction of sections bearing on work which falls within the province of the physical chemical laboratory. Sections dealing with the use of indicators in the determination of p_H values and with the methods employed in the determination of freezing-point curves, for instance, would certainly not be out of place in such a guide. The experimental treatment of types of heterogeneous equilibrium might also receive further consideration since it is only as the result of the experimental investigation of such systems, of the correlation of the experimental data and of the actual construction of diagrams and models, that the distinctive characteristics of complex heterogeneous equilibria are clearly impressed on the student's mind. Furthermore, since electrochemical preparations and electrochemical analyses very frequently form part of the experimental work which is carried out in the physical-chemistry laboratory, it would obviously be of advantage to many students to have short sections devoted to these matters included in the volume.

Whilst, however, there may be considerable differences of opinion amongst teachers of physical chemistry as to what should be included in the compass of an ideal course, there can be no divergence in reference to the view that the high reputation achieved by Findlay's book as a trustworthy and efficient laboratory guide will be fully maintained by the fourth edition. The new material is clearly and adequately expounded, and the more extensive introduction of notes and bibliographical references undoubtedly adds to the value of the book which in its external aspect has been made distinctly more attractive by the substitution of Demy 8vo format for the Crown 8vo of the older editions.

H. M. Dawson

Elementary Physical Chemistry. *By* W. H. Barrett, M.A. *Pp. viii*+243. *London: Edward Arnold and Co.*, 1923. *Price* 6*s.*

This book covers the usual ground in physical chemistry, but differs from most standard books on the subject by giving instructions for performing experiments. These are designed to illustrate the principles as they are introduced, and are not, of course, intended to replace a practical course in the subject. A feature of the book is the presentation of problems at the end of each chapter; nothing assists the student more to fix his ideas on a subject than the working out of such problems. The reviewer feels, however, that the solutions of these might, with advantage, have been given. It is discouraging to the student after he has worked out a problem if he does not know whether his results are correct or not, and the teacher is not always available for every problem.

The order and method of treatment is good, so that continuity is preserved. Few errors have escaped the proof reading, though an index has been omitted in Table 31, p. 181, and the signs of the indices in Table 35, p. 212, are wrong. The book is a useful one and is available at a very low price. John A. Cranston

An Introduction to Theoretical and Applied Colloid Chemistry. *By* Dr. Wolfgang Ostwald. *Authorised translation from the eighth German edition by Dr. M. H. Fischer. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.*, 1922. *Price* 12*s*. 6*d*.

It is necessary in these days for men of science to present their work in popular form, not only to the layman, but also their fellow-workers in other branches. The five lectures in the present volume were delivered in America in 1913–14, but as they have been continuously revised by the author they have much more than a historical interest; in fact, they form an excellent introduction to colloid chemistry.

The selection of matter for such semi-popular lectures is of paramount importance, for the subject must be presented in a manner which is convincing logically and at the same time illuminated by interesting and familiar details. Prof. Ostwald has used his unrivalled command of the subject with a restraint which cannot be too highly praised. In the first lecture he defines the realms of colloid chemistry as the study of those disperse systems which lie between molecular dispersions (" true solutions ") and coarse, unstable dispersions in which the particles are usually visible under the microscope. This point of view is emphasised in the more romantic title of the German edition—*The World of Neglected Dimensions*. The second and third lectures deal with the classification and general properties of colloidal systems.

The last two lectures will be the most interesting to many readers, as they deal with the scientific and technical applications of colloid chemistry. The examples selected cover a prodigious range of human activity. Photochemistry, crystalline liquids, clouds and deltas all come in for consideration before the more obvious applications to biology and medicine. In technical matters colloidal considerations are frequently confined to the working out of a *rationale* of operations as carried out at present, though even this is the first step towards further progress. The beginnings of colloidal processes consciously undertaken are seen in the production of graphite for lubrication by Acheson's process, and in the applications of colloid mills. Many hoary controversies are illuminated by the application of the ordinary ideas of colloid chemistry, notably the constitution of gold and selenium ruby glasses, of ultramarine, and the setting of cement. The application of colloid conceptions to metallurgy is still in its infancy, and justice is done in the final lecture to the exceptionally important work of Benedicks and Gürtler. The ideas developed in relation to such matters as soap manufacture, foods, dyeing, and the vulcanisation of rubber are fairly familiar to the average colloid chemist, but will be novel to many readers.

The translation is, on the whole, good and has not made the book unreadable in its new language, as so often happens. It is, however, invidious to speak of " the classification of *the* colloids " when any substance can take on colloidal form.

The author frankly describes his work as " a propaganda sheet for colloid chemistry." As such it is not to be regarded as a substitute for the systematic works but rather as a stimulus to the study of them. It indicates to the chemist and the manufacturer where they stand with regard to a new and lively science. It is an antidote to the prevalent preoccupation with the crystalloid state of matter, and is particularly to be recommended to minds like that of an eminent professor, who recently remarked to the present reviewer, " When I see a colloid, I pour it down the sink."

P. C. L Thorne

Quantitative Chemical Analysis. *Part I By* Prof. R. M. Caven, D.Sc., F.I.C *Pp. vii*+153. *London: Blackie and Son. Ltd.*, 1923. *Price* 3*s*. 6*d*.

This volume is Part I of a book which is intended to provide instruction for the student of chemistry, after he has passed the most elementary stage, until he is ready to take an honours degree, or diploma, such as that of the Institute of Chemistry. It is based on the work carried out normally by the full-time student in the Royal Technical College, Glasgow. Some simple inorganic preparations with their gravimetric analyses are given at the commencement, but the main portion of the book is devoted to volumetric analysis. Exercises are set in the preparation and uses of standard solutions of acids and alkalis, of potassium permanganate, of potassium dichromate, of iodine and sodium thiosulphate, and of silver nitrate.

The long and successful teaching experience of the author and his well-known lucidity are reflected in the precise and systematic way in which the subject is presented and in the useful hints with which it is rounded off. The publication of Part II of the book will be looked forward to with interest.

W. O. Rutherford, vice-president of the B. F. Goodrich Rubber Co., New York, has been elected president of the Rubber Association of America.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Sept.* 13)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Brassware	7438/3/T.E./E.C./2
Australia	Sodium acetate (tender)	12039/E.D./C.P.
Belgium	Chemicals, pharmaceutical products	291
Brazil	Photographic materials	905/3/F.G./C.C./2
British India	Enamelware, paint (tender)	*
Bulgaria	Creosote (tender)	11456/F.E./C.C./2
Canada	Pulp and paper machinery, brass, copper	289
Finland	Iron, steel, brass, copper	292
Latvia	Lubricating and cylinder oil (tender)	7986/F.R./C.C./2
Norway	Tinplate, olive oil	293
Poland	Coconut and soya bean oil	7931/F.R./C.C./2
Spain	Paint, soap, cement	294
Uruguay	Electrolytic tinned copper wire (tender)	8646/F.L./C.C./2

* Director General, India Store Department, Branch No. 10, Belvedere Road, London, S.E.1.

TARIFF CUSTOMS EXCISE

Bahamas.—Kerosene oils may be imported duty free.

Germany.—The tax on starch sugar has increased to 2,900,000 marks per 100 kg., and to 7,300,000 marks per 100 kg. for other sugar.

Portugal.—Modifications have been made in the duties on sugar and tin manufactures.

South Africa.—A dumping freight duty has been levied on imports of superphosphates and cement.

France, Czechoslovakia.—The issue for September 13 gives a list of reduced duties on goods provided by the Convention concluded on August 17. These reduced rates are applicable to similar goods produced or manufactured in the U.K. and in such other parts of the British Empire as accord the most-favoured-nation treatment to goods from Czechoslovakia.

REPORT

Report on the Industrial and Economic Conditions in Norway, Dated February, 1923. *By* C. L. Paus, *H.M. Commercial Secretary, Christiania. Department of Overseas Trade. Pp.* 81. *H.M. Stationery Office,* 1923. *Price* 2*s.* 6*d.*

The general economic crisis was felt in Norway with increasing severity in 1922. Competition from abroad is serious, and although labour costs have decreased, further wages reductions will have to be effected. Increased industrial activity has led to an increase in the consumption of raw materials, but to some extent this has been met from existing stocks. There have, however, been demands for fresh supplies and the comparative stability of the krone has facilitated transactions in foreign currencies.

Agriculture passed through a critical year, prices—and consequently profits—being low. Lumbering operations were restricted, owing to large stocks of timber being held by the pulping mills. The position of fisheries improved somewhat. In 1922, 1,745,000 gals. of cod liver oil was produced, against 1,263,000 gals. in 1921. No new hydro-electric power schemes have been inaugurated, as new supplies of energy are required only for domestic purposes.

The principal difficulties with which industry had to contend in 1922 were, as in the previous year, high production costs and foreign competition (*Cf. J.*, 1922, 222 R). Large stocks of raw materials bought at high prices hampered the wood-pulp and paper-making industry. The financial condition of this industry is weak, but improvement is expected, as the decrease in British demands has been counterbalanced by a huge increase in exports to the United States and Canada. Exports of cellulose in 1922 are estimated at 225,000 t., of which 25,000 t. was drawn from existing stocks. High production costs and restricted demands have limited the activity of the mining industry, though 400,000 t. of pyrites and 150,000-200,000 t. of iron ore were produced, compared with 231,000 t. and 55,000 t. respectively in 1921; the prices obtained, however, were often less than the cost of production. The copper smelting works, nickel refineries, and nickel, chrome, and molybdenite mines were closed during the whole of the year. Carbide factories were working at about 30 per cent. of capacity, but they have cleared old stocks and are no longer working at a loss. The production of ferrosilicon was about 10,000 t. (half the normal capacity), and exports remained at the same level as in 1921, but were unremunerative. Only about 1000 t. of ferrochrome was produced; an increased demand from Great Britain is now noted, however. The nitrate factories belonging to the Norsk Hydro-elektrisk Kvaelstof A.-S. operated at full capacity in 1922, despite keen competition from Germany. Aluminium factories worked at about one-half their capacity (8000 t. per annum), but demands have now increased. During the year the output of cement was 1,500,000 barrels.

Following are the quantities (in tons) of various commodities imported in 1922, the figures for 1921 being given in parentheses:—Cement, 9576 (18,189); fertilisers, 42,314 (23,540); coal, 1,748,657 (896,593); iron, 90,375 (57,759); copper, brass, aluminium, etc., 1146 (1826); zinc, 3,739 (7635); lead, 750 (379); tin, 167 (212); potash, 1163 (257); bleaching powder, 1662 (354); salt, 183,927 (121,292); Glauber's salt, 10,121 (3740); soda ash, 23,773 (6838); caustic soda, 1741 (858); sulphur, 11,662 (4919); sulphuric acid, 184 (250). Exports included aluminium, 6043 (6266); calcium carbide, 21,004 (15,676); cellulose, 205,775 (82,456); cement, 88,714 (47,962); copper, 177 (894); ferro-chrome, 1426 (528); ferro-silicon, 9846 (5,824); iron ore, 185,307 (7107); matches, 2374 (2442); molybdenite, 15 (59); nitric acid, 1116 (794); ammonium nitrate, 1792 (13,103); sodium nitrate, 32,401 (17,314); sodium nitrite, 1674 (1619); calcium nitrate, 157,558 (81,876); cyanamide, 3899 (5,339); pyrites, 475,864 (223,879).

COMPANY NEWS

BRITISH CELLULOSE AND CHEMICAL MANUFACTURING CO., LTD.

The accounts for the 20 months ending Feb. 28 show a net loss of £491,783, including £210,538 loss on trading account, £229,270 depreciation of surplus unerected plant and losses on plant sold or wholly written off. Transfer fees amounting to £1261 were received, whilst £50,695, representing the balance of the reduction of capital account, was appropriated to meet the losses. The report states that recent developments and extensions will ensure great economies in the cost of production when the demand is increased; and that since the accounts were closed the monthly earnings have been more than sufficient to cover all charges and the debenture interest, but not to meet depreciation. Since the last report was published the authorised capital has been written down from £7,750,000 to £6,000,000, and the Cellulose Holdings and Investment Co., which was formed under the reconstruction scheme, recently agreed to provide the company with £400,000 of new capital. The issued ordinary preference capital amounts to £5,400,000, and the first mortgage debenture stock to £700,000, the company having the right to issue an additional £300,000 of similar stock if required. Freehold land, buildings, plant, machinery, and equipment are valued at £3,445,376, goodwill, patents and patent rights being valued at £1,886,451; stocks amount to £176,494, and cash to £102,580. It is proposed to change the title of the company to British Celanese, Ltd.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric ..	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw. ..	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 10s. per ton makers' works.
Ammonia Alkali ..	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White) ..	£72—£73 per ton. Not much doing.
Bleaching Powder ..	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride ..	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate ..	£25 10s.—£26 per ton.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate ..	6¼d. per lb. d/d.
Potass. Chlorate ..	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. More inquiry for forward delivery.
Brown Sugar of Lead	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.—1s. 2½d. per lb. Good demand. Market firmer.
Crude 60's	3s. 3d.—3s. 6d. per gall. Good demand for spot delivery.
Acid Cresylic—97/99	2s.—2s. 5½d. per gall.
Pale 95%	1s. 10d.—2s. 5d. per gall. Market weaker.
Dark	1s. 10d.—2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price.
Anthracene Oil—	
Strained	8¾d.—10d. per gall. Supply short.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	1s. 1½d. per gall.
Standard Motor	1s. 6½d. per gall. delivered buyer's works.
Pure	2s.—2s. 1d. per gall. d/d. buyer's works.
Toluole—90%	1s. 7d.—1s. 10d. per gall.
Pure	2s. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9¾d. per gall. Fair enquiry.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 5d.—1s. 6d. per gall.
Solvent 90/190	1s. 3d.—1s. 6½d. per gall.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Supply short.
Whizzed or hot pressed	£11—£12 per ton.
Naphthalene—	
Crystals	£20 per ton.
Flaked	£20 10s. per ton.
Pitch, medium soft	132s. 6d.—145s. per ton. Market quiet.
Pyridine—90/140	19s.—20s. per gall. Market very strong.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 10d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 7d.—1s. 8d. per lb. Market weaker.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d.—10d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 0d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Prices firm with a good steady demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.

Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 1d.—3s. 2d. per lb. Good demand. Firm market.
Acid, Benzoic	2s. 3d.—2s. 6d. per lb. Some German makers are stated to be out of stock.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 5½d.—1s. 6d. per lb., less 5%. Supply exceeds demand.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb., according to quantity.
Acid, Salicylic	2s. 2d.—2s. 3d. per lb. Firm market. Good inquiry.
Acid, Tannic	3s. 3d. per lb. for B.P. quality.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market continues weak.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. for English manufacture. Imported higher. Market very quiet.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	17s. per lb. for quantity.
Benzonaphthol	4s. 6d.—4s. 9d. per lb. Slight advance in price.
Bismuth Salts	A steady market.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	6½d. per lb.
Ammonium	7d. „ „
Sodium	7½d. „ „
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.
Chloral Hydrate	3s. 9d.—4s. per lb. Somewhat firmer. English makers are oversold.
Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	75s. per cwt. ex wharf London.
Guiacol Carbonate	8s. 6d. per lb.
Hexamine	3s. 6d. per lb. Firmly held.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s.—3s. 3d. per lb. Now asked.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate—	
Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality & quantity.
Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 4d. per lb. Distinctly firmer for English or imported, in view of normal increasing demand.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid: Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9d., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 5d. per lb.
Paraldehyde	1s. 5d. per lb. Demand slow.
Phenacetin	6s. per lb. Unchanged.
Phenazone	7s. per lb. Steady.
Phenolphthalein	6s. 6d.—6s. 9d. per lb., according to quantity and holder.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	2s. 8d. per lb. English makes are meeting foreign competition.
Potass. Iodide	15s. 8d.—15s. 11d. per lb. Good demand.
Potass. Metabisulphite	8d. per lb.
Potass. Permanganate	10d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz. Steady market.
Resorcin	5s. 6d. per lb.
Salol	3s. per lb. Limited demand.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 6d. per lb. Improved demand would lead to higher prices as present stocks cannot be replaced at current figures.
Sod. Citrate, B.P.C. 1923	2s. 3d. per lb.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	Powder 2s. 6d.—2s. 7d. per lb., and Crystal at 2s. 7d.—2s. 9d. per lb. Prices are likely to move slowly upwards as the season advances.
Sod. Sulphite, anhydrous	£25—£26 10s. per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate	3s. ,, ,
Cinnamic Aldehyde Natural	18s. 6d. ,, ,,
Coumarin	18s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	10s. ,, ,,
Geraniol (Palmarosa)	35s. ,, ,, Advanced.
Geraniol	5s. 6d.—12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. per lb.
Linalol ex Bois de Rose	18s. 6d. ,, ,,
Linalyl Acetate	21s. ,, ,,
Methyl Anthranilate	9s. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Xylol	11s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,
Rhodinol	45s. ,, ,,
Safrol	2s. 1d. ,, ,,
Terpineol	3s. ,, ,,
Vanillin	22s. 3d.—23s. 6d. per lb. Firm with steady demand.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	30s. ,, ,,
Camphor Oil	75s. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4½d. per oz.
Cassia Oil 80/85%	12s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 2d. ,, ,,
Ceylon	3s. 10d. ,, ,,
Clove Oil	8s. 6d. ,, ,,
Eucalyptus Oil 70/75%	2s. 6d. ,, ,,
Lavender Oil	18s. 6d. ,, ,,
Lemon Oil	2s. 10d. ,, ,,

TRADE NOTES

Mauritius in 1921

The colony was prosperous during 1921, despite a fall in the prices of sugar. Exports of sugar totalled 229,225 metric tons, compared with 182,425 t. in the previous year. The exports reached a total value of 157,249,822 Rs., including 287 t. of aloe fibre, as well as rum, vanilla, skins, coconut products, etc. Aloe fibre is now grown over 20,000 acres, and coconuts are cultivated over about 800 acres. A certain area has been planted with sisal, but although vanilla is cultivated its export is negligible. Imports were valued at 105,744,980 Rs., the United Kingdom supplying goods (chiefly textiles, machinery, hardware and soap) to the value of 40,563,000 Rs. Drugs, perfumery, olive oil and indigo are mainly obtained from France and coal from South Africa.—(*Col. Rep.-Ann.*, *No.* 1149, 1923.)

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications made in August for licences under the Dyestuffs (Import Regulation) Act, 1920, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 391, of which 269 were from merchants and importers. To these should be added the 29 cases outstanding on August 1, making a total for the month of 420. These were dealt with as follows:—

Granted, 282 (of which 248 were dealt with within seven days of receipt).

Referred to British makers of similar products, 74 (of which 63 were dealt with within seven days of receipt).

Referred to reparation supplies available, 30 (all dealt with within two days of receipt).

Outstanding on August 31, 34 (mostly dealt with at the meeting of the Committee held on August 31).

Of the total of 420 applications received, 341, or 81 per cent., were dealt with within seven days of receipt.

Japanese Camphor Trade in 1922

H.M. Commercial Counsellor, Tokio, reports that during 1922 the Japanese export trade in camphor showed a marked recovery, the exports amounting to 36,000 piculs as compared with 14,000 piculs and 10,000 piculs respectively in the two previous years, whilst during the March quarter of 1923, the exports of camphor amounted to 14,000 piculs. A large proportion of these exports go to the United States, other large buyers being India and Germany.—(*Bd. of Tr. J.*, *Sept.* 6, 1923.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, SEPTEMBER 28, 1923 No. 39

EDITORIAL

OUR attendances at meetings of the British Association have been so few and far between that the proceedings and atmosphere still have the charm of novelty. Some of the members regularly attended the particular section to which they were attached; others impartially flitted from chemistry to physics and botany, with occasional visits to education or psychology. They sipped each flower and changed every hour; for are not all sciences here united? It may have been a set of curious chances or it may be a sign of the times, but in several sections we found attention concentrated on things of molecular or even atomic dimensions. Our recollection of chemistry forty years ago is that the science was then more massive; half a pound of iron filings mixed with half a pound of sulphur and buried in a neighbour's flower garden constituted an experiment which he who ran could read. But now we have to consider enzymes which, according to Dr. E. F. Armstrong, are not substances but little inflammations breaking out on the surface of some colloid complex, and we are drawn into the realm of the infinitely little. The small volcano in the flower garden has to be reduced to dimensions where a surface only one molecule thick affords a clue to some catalytic phenomena. In physics our atom-smashers and orbit-weavers, lineal and worthy descendants of Newton and Laplace, trace the effect, on spectral and other manifestations, of the removal of so small a particle as an electron, while botanists and physiologists bring photosynthesis, osmosis, surface tension, hormones and other physical and chemical conceptions to aid them to see the way in which plants and animals construct their cells and fill them with complex materials. The enzyme theory seems " so like the truth 'twill serve our turn as well." The chemistry of the mass has given way to the chemistry of the surface; the study of the leaf has been displaced by the study of the membrane. It is probably due to these facts that integration is necessary to make the explanations intelligible to ordinary minds. But the discussions are in some cases a little difficult for the ignorant. Did not someone say, " They were not made for thee, less thou for them "?

There is a social side to the British Association which is certainly very pleasant and probably very valuable. In the fine reception room much casual conversation was possible, and many of those who had read serious papers found it a relief to intermix grateful digressions. Here one group seemed to be discussing the scientific exhibit at the British Empire Exhibition next year, a record of the achievements of British chemistry during modern times; there, another small knot of chemists appeared to be considering some sort of co-operation among our many societies, a place or, if not, at any rate, a scheme in which their various activities could be more conveniently fitted, as in the Ark, joined without force or strife, all creatures dwelt. In the University Club others foretold the future of chemistry, still—and perhaps always—in its infancy, for that which never is to die for ever must be young. The hospitality offered to the visitors was very generous. As we wandered about our host's garden, admiring the dahlias and watching the great ships go by, we were reminded of the description given by Milton many years ago of his idea of the manner in which the wealthy merchant might welcome a valued guest: " He entertains him, gives him gifts, feasts him, lodges him; his guest comes home at night, prays, is liberally supped, and sumptuously laid to sleep, rises, is saluted, and after the malmsey or some well-spiced brewage, and better breakfasted than he whose morning appetite would have gladly fed on green figs between Bethany and Jerusalem, his guest walks abroad at eight and leaves his kind entertainer in the shop trading all day." This with a change of only two words is what the old poet considered the true hospitality, and though nowadays the evening prayer and the malmsey before breakfast are not universal, the rest of the description could well be applied to the treatment of chemists by their hosts at Liverpool and the vicinity.

* * *

On reading through the crowded list of papers read before Section B (Chemistry) of the British Association, we saw that Prince

Ginori Conti was announced to speak on the utilisation of volcanic steam. This reminded us of the presidential address which Prince Conti delivered in opening the First National (Italian) Congress of Pure and Applied Chemistry held in Rome in June. Very appropriately, Prince Conti took advantage of the occasion to consider the chemist's standing in public estimation, and said that before the war the chemist was considered either as a superior kind of pharmacist or as a magician who, with a wave of his wand, could perform miracles. But the wartime shortage of drugs, dyes and explosives, forced the public to face facts, and thus educated it to a more just appreciation of what the chemists' work really consists. It seems somewhat doubtful if the public appreciation of chemistry is really so far advanced as we could wish, though there has certainly been an improvement. The daily papers are giving more space to, and better accounts of, scientific matters, the demand for popular expositions is growing, and, altogether, signs of greater interest in chemistry are not wanting. But there are also indications that the lessons so painfully taught by the war are in danger of being forgotten. Public appreciation of chemists and their science seems to be hampered by two main difficulties. The confusion, unequalled in any other country, due to the popular interpretation of the title "chemist" is partly responsible. The subject has been discussed long and oft, but it seems of little avail to protest as long as another section of the community has the legal right to utilise the title. In any case, however, the passage of time and the odour of sanctity conveyed by good works will, if we can be content to wait, surely bring a remedy. The other difficulty is, perhaps, even more important as it tends to prevent us from being understanded of the people ; we refer to the technical vocabulary of chemistry. We may give an illustration : Recently, an important provincial paper published a letter from a correspondent who quoted part of the description of how to prepare an organic chemical as an example of incomprehensibility, and then inquired how business men could be expected to understand such jargon. It is strange to us that names such as *Taraxacum densleonis* or *Ceutorhyncus troglodytes* are quoted glibly by people who—so we are asked to believe—are overcome by some kind of phobia when faced with 1-mercapto-2-aminoanthraquinone or hexa-chloro-*p*-xylene. That some kind of virtue resides in the purely "intellectual" value of the one as opposed to the possible commercial use of the other must, we suppose, be advanced as explanation of this difference in mental attitude. But the difficulty is there, and it is more than ever necessary for technical results to be translated into language that can be understood by non-technical persons.

CHEMISTRY IN FRANCE IN THE XVIIth AND XVIIIth CENTURIES

By C. A. SILBERRAD, B.A., B.Sc.

It is always stimulating to have a subject treated in a new way, and still more so when this is well done. There are many works giving the history of chemistry in varying degrees of detail, but there seems to be none on the lines of the one by Dr. Helène Metzger, of which the first volume has just appeared.* Her aim is to trace the development of chemistry during the seventeenth and eighteenth centuries by showing the general state of scientific opinion at the time at which each chemist wrote or worked so as to set his views and discoveries in their correct intellectual surroundings. She gives no biographical details, and emphatically does not hold with Delacre that the only important thing is to determine what each man did, but endeavours to show how the general scientific opinion of the time acted on the various chemists and how their work acted on general scientific opinion. She has confined herself to French chemists and those whose works were translated into French or had any real influence on French chemical thought.

She takes as a starting point the publication of Lemery's *Cours de Chimie* in 1675, and begins by showing what views had been current during the first three-quarters of the seventeenth century, and what was the intellectual *milieu* into which Lemery's book came.

At the beginning of the seventeenth century there was no universally accepted doctrine in chemistry ; to a very large extent each successive savant set himself to evolve a theory to explain all known chemical phenomena, and incidentally the universe as well, with little or no reference to any theories previously propounded. Yet, though at first sight independent, certain general trends of thought are discernible. At this time chemistry was still very largely regarded as a branch of metaphysics, and theories were chiefly made *a priori*, experiments being subsequently interpreted in terms of the theory and not *vice versa* as nowadays.

In the period preceding the publication of Lemery's book the best known authors were Jean Beguin, Davidson, Etienne de Clave, Arnaud, Lefèvre, Glaser, Thibaut and Malbec de Tressel.

Jean Beguin deems the end of chemistry to be the preparation of remedies, and adheres to the three "principles" of Paracelsus—salt, sulphur and mercury, which by this time, to some extent at least, had come to mean qualities rather than substances. Thus they are never obtained pure, but always mixed with more or less of "phlegm" and *caput mortuum*, and this was held to cause much difficulty in the analysis of bodies. He gives considerable details regarding apparatus and experiments.

---

* *Les Doctrines Chimiques en France du début du XVIIe à la fin du XVIIIe siècle.* By Dr. Helène Metzger. Part I. Pp. 496. Paris : Les Presses Universitaires de France, 1923. Prix 25 fr.

Davidson is primarily a metaphysician and disregards the medical side of chemistry almost entirely. He holds to Aristotle's four elements (earth, air, fire and water) and also the three "principles" of Paracelsus, "whose mutual reactions produce all bodies." As a consequence, he believes in transmutation, and holds that in solution the solvent "dissolves that which it recognises as more or less homogeneous with itself," thus endowing it with a quasi-intelligence.

Etienne de Clave's work is in marked contrast with that of the author previously named. He discusses the various theories of his predecessors and gives reasons for rejecting them and for adopting his five "elements"—water (phlegm), spirit (mercury), sulphur (oil), salt and earth—which he deems mutually inconvertible, but like others appears to confuse qualities and substances. These five elements in various proportions form all substances. He gives, however, very few experimental results.

Arnaud rather resembles Beguin and defines chemistry as "the art of separating the pure from the impure by means of fire in order to prepare remedies or to perfect the metals." He gives numerous details of chemical processes, but little or no theory, and holds pulverisation to be the chief operation, every chemical operation resulting "in making the powder finer or coarser."

Lefèvre more resembles Davidson in that he goes into much metaphysical detail. He argues in favour of experiment, yet gives practically no account of any experimental work. He holds that the source and root of all things is the "universal spirit," which has in itself "three substances distinct and not different . . . . a hot, a damp and a dry," and which is accordingly "triple in its name, in that by its natural fire it is called sulphur, by its moisture it is mercury, and by its dry root connecting the dampness and fire it is called salt." By the action of certain "ferments" (not further described) this spirit takes the form of various bodies and becomes materialised, adopting more or less of the characters of sulphur, mercury or salt, according to the substance which it becomes—the precise process is decidedly obscure. He holds, however, that all substances can be resolved into two or more of five elements, which are well exemplified when dealing with the distillation of organic materials. They are :—Phlegm, or the watery distillate ; spirit, the gaseous portion ; sulphur, the oily combustible matter ; salt, the part of the solid residue soluble in water ; and earth, the insoluble portion. The chemist can only separate or transfer those elements, which are pre-existent, and consequently he holds transmutation to be possible though not yet effected. Fire, according to Lefèvre, goes towards heaven because "like attracts like." Air is the matrix of the universal spirit, and does not form a part of any compound body, its assistance to combustion being due solely to its removing the products thereof. He gives many "analyses" of organic and inorganic materials which he interprets in the light of his theory, but not forgetting that the main object of such work is the production of remedies.

Glaser accepts the five "principles," which, however, signify rather classes of bodies, but he mainly confines himself to practical details, especially of metals and their compounds.

Thibaut likewise is almost entirely free from theoretical considerations, only giving practical details regarding the apparatus used and the methods of carrying out experiments. He holds that precipitation is due to a combat between the added precipitant and the solvent.

Malbec de Tressel endeavours to uphold the older views ; he adopts the four Aristotelian elements and the three Paracelsian principles, but his views are decidedly confused. He gives, however, accounts of various operations.

The authoress, having thus outlined the theories actually current during the earlier part of the seventeenth century, proceeds to greater detail and begins (Chap. II.) with a sketch of the place held by the "philosophy of metals" in chemical theory at that time.

In early times a close connexion was assumed between the seven planets and the seven known metals, doubtless mainly because both were seven in number and both are bright ; then when astrology came to connect the various parts of the human body (also deemed seven in number) with the planets, it was natural to assume the corresponding metal to have a special influence on that portion of the body. But when more metals were discovered the connexion with the planets came to be regarded as doubtful.

The similarity in appearance of the metals is probably the root cause of the belief in transmutation. A close analogy was also assumed to exist between the organic and inorganic worlds, and metals were regarded as growing or ripening, the imperfect metals developing into the perfect metal gold, and the alchemist sought to accelerate the process. Their ideas are various and somewhat confused, but one chief line of thought appears to have been that gold of itself has no power of assimilating the baser metals unless there is present a special digestive ferment, the philosopher's stone ; and one great object of the adept was to obtain this so as to enable the "seed of gold" (regarded as present in gold) to assimilate to itself the base metals on which it feeds. Further, just as water is necessary to the growth of a plant, so is a liquid necessary to the growth of gold, and this liquid is the "mercury."

Views on the actual composition of the metals were also confused. That they were more or less similar in composition was held certain, both by reason of the general similarity of their properties and as regards several of them by their more special properties. Thus it was held that lead and mercury must be specially closely related by reason of the similarity of their effects on those who worked with them. The general view was that they consisted of mercury and sulphur in varying proportions and of varying purity, though neither the mercury nor the sulphur was the substance now known by that name. Mercury was regarded as the essentially metallic character, the "species of matter which Nature has made to produce gold from"; sulphur was that which by its presence together with the mercury formed the baser metals.

An alternative and later view was that there was one essential metallic substance common in greater or less degree to all metals, but in each metal combined with some material special to that metal, so that to change one metal into another required substitution rather than transmutation.

It must further be remembered that for long it was held that different species of plants were mutually interchangeable. Thus, wheat was held to be transformable into oats. On this ground it was not so unreasonable to assume metals to be changeable one into another.

Thus it appears that the ideas of the alchemists, though to us *prima facie* so fantastic, were not really so devoid of reason. For with the knowledge then available metals appeared much more similar *inter se*, and so might be assumed more easily interconvertible than a metal and its ore. Then given the premise that there is essential similarity between the vegetable, animal and mineral kingdoms, the ideas of growth and ripening follow logically, as also do those of the philosopher's stone and the "mercury."

But why do the alchemists invariably state their results in mystical and enigmatic language? To this there seems no one clear answer. It is hard to believe that all were intentional deceivers, though doubtless many were. One reason was probably the desire to keep results secret or only for those to whom they should personally explain them. Another suggestion is that of Boerhaave, that these directions state rather what it is hoped would be successful than what have been.

As time passed, however, and failure was the result of all efforts at transmutation, doubt as to its possibility became more widespread and the way became more and more clear for views such as the corpuscular hypothesis, though even Descartes held that all visible bodies are transmutable into each other—a natural deduction from his view that the ultimate particles of all consisted of the same material. The fundamental idea of the corpuscular or mechanistic hypothesis was that all bodies consisted of innumerable small particles all of the same material, those of one substance being all of the same shape and different in shape from those of all others. The possibility of changing one substance into another by changing the shape of its ultimate particles was a matter of dispute. Those who held it to be impossible became more and more numerous, and by the end of the seventeenth century the believers in transmutation were negligible in number.

The authoress next (Chap. III) considers the influence of the teachings of Paracelsus, Van Helmont and others. Paracelsus pretended entirely to disregard the teachings of his predecessors and ostentatiously burned the works of Galen and Avicenna, but none the less in reality made much use of their ideas. He laid great stress on "correspondences" and "analogies," and, though he alleged a contempt for astrology, held that there was a close connexion between the planets and the parts of the human body, and as a consequence between the various metals and these same parts. In opposition to Galen, who held that "opposites cure opposites," his view was that "like cured like," which resulted in ideas such as that because gold and the sun and the heart and the sun were regarded as closely connected, therefore gold was a remedy for diseases of the heart, as also anything resembling either, *e.g.* the citron which resembles gold in colour and the heart in shape. Or again salt and fire were analogous because both preserved organic materials from decay. These analogies were extended to the incorporeal world and resulted in fantastic and metaphysical ideas such as that of the microcosm and macrocosm. The very fantastic nature of these developments gradually destroyed them, and with them also the ancient and mediæval philosophy. The great contribution of Paracelsus to science was the incentive he gave to the study of the metals.

In his contempt for Aristotle, Galen and his predecessors generally, Van Helmont resembled Paracelsus, and his system, fanciful though it appears, is a violent reaction against the scholastic philosophy, and is really a systematisation of material phenomena as known to him, always limited by the necessity of conformity with the Biblical cosmogony. He holds that the prime material of all bodies is water, whence everything is derived by the action of specific ferments, which either are, or are accompanied by (it is not clear which) a directing spirit termed the "archeus." (Compare *Genesis* i, 2. "The spirit of God moved on the face of the waters.") That water is the one basic material is held proved by various alleged facts, such as that plants produce solid matter from water, and that water, when evaporated, leaves an earthy residue. The idea of the alcahest or universal solvent is invented whereby all things are reducible to "water." The superior density of many substances is attributed to compression of the water forming them. Air was, however, held to be a separate element, not transmutable into water. It did not support combustion, but was the medium that carried away the products thereof. Van Helmont appreciated the existence of other substances similar to but different from air, and invented the term *gas* to denote them. These substances he held to be transmutable into water, having apparently been led to this view by discovering that water is convertible into steam and back again to water with no change of weight. Later it was observed that air and gases were essentially similar and Van Helmont's "air" came to resemble rather the modern ether. Van Helmont's theories did not spread, and his most important contribution to science was probably his making the constancy of matter as measured by weight the basis of his experiments, though for the time being the chief influence of his views was that they greatly assisted in the final overthrow of the older theories and by holding all matter to be derived from one prime material helped to lead up to the corpuscular hypothesis. The search for the alcahest and for evidence that water was the basic material of all things induced much experimental work.

Next come the dualistic views based on the intrinsic opposition between acid and alkali, whence contrariwise acid and alkali were held to be present wherever any mutual action occurred. Anything soluble must be alkali, and any solvent acid. Thus all fermentation was the result of acid and alkali, and everything in nature including the digestion (solution) of food was explained by the theory, which like its predecessors fell beneath the weight of the subsidiary theories required to "explain" facts, but also like its predecessors was of some value in inducing experimental inquiry. It was finally more or less assimilated by the corpuscular theory which held that acids consisted of sharp pointed particles fitting into holes in the porous particles of alkalis.

The supporters of these various theories disputed with each other in no measured terms, and the authoress gives as an example the famous quarrel regarding the use of antimony in medicine, which, beginning in the sixteenth century was revived in the seventeenth, and formed the subject of a decree of the Parliament of Paris in 1666 authorising the use. The one party urges for example that as antimony cleanses metals so its compounds must cleanse the human body, to which the other retorted that it does this by killing the body and so cleansing it from all earthly impurities; the opponents of either party are stigmatised as charlatans, robbers, fools, infidels, heretics, abortioners, bastards, forgers, etc.

The authoress next traces the currents of thought which led up to the various corpuscular or mechanistic theories. Gassendi held that all substances consist of differently shaped hard particles in perpetual movement in a void, a theory practically, though not theoretically, in agreement with that of Descartes, who, however, added two other forms of "matter," one very subtle, forming the "soul of the world," the other less so, but still much less dense than ordinary matter, being the "material" which conducts light. These three forms of matter he held to fill all space completely. Similar views were held by Boyle, who considered that all bodies consist of infinitely small particles, differing in shape and movement. But it was the clear account he gave of his experimental work that gave him the great influence he had.

In this way the corpuscular theory in one form or another spread throughout the scientific world, and chemistry was to be reduced to ascertaining the shapes of the ultimate particles of which matter consisted, abandoning all attempts to explain the universe. There was still confusion as to what bodies were simple, how far acids differed *inter se*, etc., but Boyle must be regarded as "a true predecessor of our modern chemistry."

Having in this way shown what was the chemical "atmosphere" at the time (1675) of its appearance, the authoress gives an account of Lemery's views as disclosed in his book (*Cours de Chimie*). Lemery scarcely notices, save to disdain, the old scholastic theories and adopts the corpuscular theory without remark as though it were self-evident and generally accepted, but goes into no detail to enable us to decide whether he followed Gassendi's view of particles in a vacuum or Descartes' of a plenum. He endeavours to avoid all description that is mystical or ambiguous, and to base his accounts on actual experiment. Adopting the corpuscular theory he seeks to explain the properties of bodies by the shapes of their ultimate particles, but does not go into great detail. His atoms are endowed with cohesion and hardness. To some extent he adopts the acid-alkali theory already noted, but appears at times to overlook what he has said about it. His experimental facts are really the result of experiment and not what he hopes may be carried out. For every result he has an explanation, though sometimes one that, to modern ideas, appears fanciful.

But as the corpuscular hypothesis suggests little connexion between the various experiments and no theory as regards the composition of compound bodies, he adopts to a greater or less extent the theory of the five principles (mercury, sulphur, phlegm, salt and earth), deducing them from the results of distilling organic matter. But he does not lay great stress on the theory, being quite content to view most of the metals at any rate as primitive entities which cannot be decomposed by human agency, although they may consist of two or more of the "principles."

In short, Lemery shows a great advance towards the modern method of subordinating theories to facts—and of facts he gives many. But it is often hard to interpret his meaning, owing to the impurity of many of the reagents and the confusion of nomenclature. Thus vitriol meant originally ferrous sulphate, then any salt of sulphuric acid, but also came to include other metallic salts, lunar vitriol being nitrate of silver, whilst vitriol of copper included the nitrate and acetate. He gives much information regarding the metals, but his treatment of the chemistry of animal and vegetable matter produced but little result, being mainly limited to distillations and the preparation of drugs. He distilled some 14,000 plants, but was only able to deduce therefrom that this method led to nothing definite, and gradually came to the conclusion that there must be intermediate or proximate principles, and to doubt the true simplicity of the five "principles." Some of his ideas are decidedly fanciful: thus a viper's poison is harmless when swallowed, but dangerous when introduced into the system by the animal's bite, because in the latter case it is violently inserted by the animal by reason of its shape, "which is long and narrow like a gun." But on the whole his work is a great advance on anything that had preceded it in France, and ranks in that country much as the works of Boyle do in England.

The authoress next considers the various views held regarding fire, combustion and calcination. Aristotle held fire to be a principle of lightness diminishing the weight of that to which it was added, and for long it was held to be a definite element. But during the seventeenth century this view was by no means invariable. Van Helmont queried whether it were not an ephemeral phenomenon; the corpuscular theory viewed it as a form of motion, and this was Descartes' view. Though the necessity of air to support combustion and the analogy between combustion and respiration were observed, it was for long believed that there was nothing in the shape of chemical reaction between the air and the body burned. John Mayow held that combustion was due to certain foreign ("igno-ærial") particles in the air. R. Hooke viewed combustion as due to a "kind of particle which rises from the earth." He recognised that air was unnecessary if these particles were otherwise supplied, as in gunpowder.

It was long before the connexion between calcination and combustion was realised. Calcination was "pulverisation by means of fire," and ranked with coagulation and precipitation as a process rather than a chemical reaction. The increase of weight was long regarded as an accident and by no means essential, and was variously explained by such views as that the metal was killed on being calcined and so weighed more, just as it was thought a body weighed more when dead than when living; or else that a volatile salt was attracted from the fuel.

Boyle held light to be corporeal and flame a luminous matter which can combine with other bodies and is able to traverse the walls of vessels. Homburg's view was that a "sulphur principle," which is much the same as the "matter of fire," escapes when a substance burns, whereas when a metal is calcined it combines with this sulphur principle and so increases in weight. It is the escape of the "matter of fire" which causes flame.

Jean Rey seems to have been the first to have thought that the increase of weight on calcination was due to the air, but supported this view by such fantastic arguments that it was accepted by none. He does not, however, conceive of combination occurring, holding rather that the air is entangled in the particles of the metal as water in wet sand.

Cherubin held that so far from any "matter of fire" or other material passing through the walls of the vessel (as held by Boyle), the very reverse must take place, as after calcination in a closed vessel air enters on opening it.

Stahl then placed the cause of combustion in the combustible body itself, holding that in both combustion and calcination phlogiston was evolved, and so at least perceived the essential similarity of the two processes; any increase in weight he held to be due to "foreign particles in the air." This view held ground until Lavoisier showed that what really happened was the evolution of heat and gain of oxygen, an essential and not an accidental constituent of the air. What led up to this change of view is to be the subject of future volumes.

The problems of calcination and combustion were by far the most investigated of all; but others also interested chemists, chief among which were the alleged analyses and syntheses of sulphur; the artificial production of fire from its elements; the nature of phosphorus, discovered at this time by Brand and Kunckel; and the relations of acids and alkalis, subjects which are all treated in this volume.

The differences between the various acids were realised and attributed by Homburg to "different modifications of the same elementary principle." The replacement of one metal by another in combination, as silver by copper and copper by iron, attracted much attention and led first to Geoffroy's theory that if two substances united together came in contact with a third "more nearly related" to one of the two it is replaced thereby, and then later to Bergmann and Berthollet's "affinities."

Thus the mechanistic view or corpuscular hypothesis gradually spread without its being precisely known how. But it left much indeterminate, and when it descended into details, such as the actual shapes of the atoms required to explain various properties and reactions, it became fantastic. Heat was generally explained as due to rapid movements of the ultimate particles, but cold was regarded as an actual substance made up of "pointed particles penetrating the flesh." Solution caused much controversy, though the usual view was that the particles of the solvent being in rapid motion separated the particles of the solute "much as a strong wind does particles of dust," though some held that mutual attractions between the two were also necessary. The authoress also discusses the modification of the mechanistic hypothesis due to Hartsoeker, who held that there were two prime materials, one a continuous subtle fluid always in motion, the other a denser material divided into particles of varying shapes.

Gradually, however, the idea that the shapes of the atoms accounted for the properties fell into disfavour, as it was realised that at best they were largely imaginary, and chemists paid more and more attention to actual experiment, framing temporary theories to explain observed facts.

The foregoing sketch, which only gives the broader outlines of the argument, shows, it is hoped, that the authoress has done that which she set out to do and has done it well. The book is written in that clear style which one has come to expect in a French scientific work, and there is a useful index of the various authors referred to and, to some extent, of the points with which each has dealt. The present volume forms Part I of the work and brings the subject down to the date of publication of Lemery's book (1675).

ON THE CHEMISTRY OF HAFNIUM*

By Dr. G. von HEVESY

Zirconium, discovered in 1789 by Klaproth, was recently found to be a mixture of two different elements of " zirconium " and hafnium. Whilst the oxides of zirconium, like baddeleyite, favas and so on contain only 1—2 per cent. of hafnium, the most common zirconium minerals, the silicates of zirconium, the " zircons," exhibit a hafnium content varying between 1 and 7 per cent. The richest hafnium content is found in secondary zirconium minerals, like alvite, cyrtolith, naegeite and malakon. The zirconium extracted from this mineral contains 21 per cent. of hafnium and an earlier specimen gave a yield of 30 per cent. A specimen of cyrtolith from Rockport, Mass., contains 40 per cent. zirconium and 10 per cent. hafnium. That alvite has an especially high hafnium content was shown by Goldschmidt and Thomasen in Christiania shortly after the discovery of this element. The complexity of zirconium was discovered by following up the conclusions of the atomic theory. Bohr's theory gives a rational interpretation for the sudden appearance of the rare-earth elements in the periodic table. According to this theory the great difference between lanthanum and barium, just like the great difference between most of the neighbouring elements in the periodic table, is due to differences in the outer electronic groups of their atoms. A group of elements preceeding lanthanum shows only differences in the inner electronic groups. To such changes thus correspond only minute differences in the chemical properties; hence the great chemical similarity of the rare-earth elements. As shown by the atomic theory. these changes in the building up of the inner electron groups are brought to completion with the 71st element, cassiopeium, with which the group of the rare-earth elements comes to an abrupt end. When proceeding further to the element 72, we already encounter changes in the outer electron groups and accordingly we should expect this element to be quite different from the rare-earth elements and related in the same high degree to zirconium, as tantalum is to niobium or tungsten to molybdenum. Bury also arrived at the same result.

Hafnium was discovered by using Moseley's method of X-ray spectroscopy. To be able to determine quantitatively the hafnium content of our specimens and fractions, a known amount of the neighbouring element 73 (tantalum) was added to these and the intensity of X-ray lines due to the known amount of tantalum and unknown amount of hafnium compared. This method allows of a simple and accurate determination of hafnium in any preparation.

The methods of separating hafnium from zirconium are based partly on the different solubilities or vapour pressures of the corresponding compounds, partly on the difference in their basicity.

The most practical method of separation is the crystallisation of the double fluorides of potassium or ammonium. The mineral is melted with KFHF and the K_2ZrF_6 extracted with boiling water, in which this compound is soluble to the extent of 25 per cent. On cooling down the greater part of the salt crystallises out. The zirconium double fluoride being less soluble (2·6 per cent. at 20°) than the hafnium double fluoride (nearly 3 per cent. at 20°), the latter accumulates in the mother liquor. Still more convenient is the crystallisation of the highly soluble $(NH_4)_2ZrF_6$, soluble at 20° to the extent of 26 per cent. The ammonium double fluoride of hafnium crystallises in beautiful prismatic (pseudo-hexagonal) crystals. The next suitable method of separation is the crystallisation of the ammonium-zircon oxalate. A soluble zirconium salt, like the sulphate, is precipitated with ammonia, the hydroxide dissolved in an excess of oxalic acid and neutralised with ammonia. By crystallising the oxalate formed, hafnium accumulates in the mother liquor.

Less satisfactory is the result of the crystallisation of the complex sulphate, like the ammonium salt of zirconium and sulphuric acid. The hafnium concentrates here also in the mother liquor.

To purify zirconium from iron and other impurities it is often converted into the oxychloride. By repeatedly crystallising this compound from hydrochloric acid pure zirconium is retained. Hafnium oxychloride is less soluble than zirconium oxychloride; thus while purifying zirconium from iron, its hafnium content is raised at the same time. For example, starting from 100 g. $ZrOCl_2$ containing 1 per cent. hafnium, the 30 g. oxychloride residue obtained after 10 successive crystallisations contained a little over 2 per cent. of hafnium.

---

* Read before section B (Chemistry) of the British Association at Liverpool on September 17.

Hafnium is more basic than zirconium, and accordingly when precipitating a solution of a zirconium salt with ammonia the first precipitate contains less hafnium than the successive ones. For example, when precipitating one half of an oxychloride solution containing 1 per cent. hafnium with dilute ammonia, the precipitate contains only 0·8 per cent., whilst the hafnium content of the solution is increased to 1·2 per cent. This difference can be somewhat increased by the presence of large amounts of ammonium chloride in the solution. By boiling a solution of zirconium and hafnium with sodium thiosulphate, zirconium being more strongly hydrolysed, the first precipitate contains a larger amount of zirconium than the successive ones. From a solution of zirconium sulphate, diluted about 1 : 40, a basic zirconium compound precipitates on standing a few days at 39·5°. Also with this process, like many similar ones, the precipitate contains slightly more zirconium than the solution.

The difference in the basicity is also shown on heating the neutral sulphate of zirconium or hafnium; whereas the first mentioned compound begins to decompose above 400°, the decomposition temperature of $Hf(SO_4)_2$ lies about 100° higher.

On dissolving the oxychloride in alcohol and precipitating with ether a higher basic compound $Zr_2O_3Cl_2.5H_2O$ is formed, which was found to be less soluble than the corresponding hafnium compound. This difference in the solubilities was repeatedly used by Mr. V. Thal Jantzen and myself to purify concentrated hafnium preparations from zirconium.

In some cases, including the phosphate, salicylate and so on, the hafnium compounds were found to be less soluble than the corresponding zirconium compounds.

Like zirconium tetrachloride, hafnium tetrachloride also volatilises appreciably at about 250°, and the first distillate contains somewhat more zirconium than hafnium.

Though hafnium is to be placed in the periodic table between zirconium and thorium where formerly cerium happened to be placed, its chemical properties are not intermediate between those of zirconium and thorium, but *much* nearer to the former element. It is of interest to note that in several cases the solubility of the hafnium compound is greater than the solubility of the corresponding zirconium compound and thorium compound as well. Thus the solubility of the hafnium double fluoride is much greater than that of the thorium double fluoride and somewhat greater than the solubility of the zirconium double fluoride.

DISCUSSION ON COHESION

On September 13, Sections B, A and G (Chemistry, Mathematics and Physics, and Engineering) of the British Association held a joint discussion on "Cohesion," which was opened by Sir W. H. Bragg, F.R.S., and was continued by Dr. W. Rosenhain, F.R.S., Dr. A. A. Griffiths and other speakers. We append summaries of the contributions by Sir W. H. Bragg and Dr. W. Rosenhain.

Contribution by Sir W. H. Bragg, F.R.S.

Whatever limitations may at one time have been supposed to define the term "cohesion," and to constitute a separate section of physics and chemistry, we see now that they have no real existence. The forces that bind atom to atom and molecule to molecule are of fundamental importance to our investigations, no matter what branch of science it is that we follow.

The atoms and molecules are so small in comparison with the objects which we handle that experiment can only deal with aggregates of atomic forces. It is, therefore, very difficult to deduce the laws that govern the behaviour of the single atom. In some chemical reaction or some particular change of state the forces may be sufficiently uniform in nature to permit a definite conclusion, but in the class of phenomena which used to be considered as evidences of the action of cohesive forces, such as capillarity, the confusion is considerable; and in the ordinary experiments with rigid bodies it is complete.

In our first attempts we simplify our task by using approximations which seem reasonable, and picture the atom and molecules as centres of force which is exerted in all directions. In such ways, many of the well-known phenomena are accounted for with more or less success, such as the gathering of a liquid into drops, the principal features of surface tension, or some of the departures from perfection in a gas. No satisfactory results are found in the case of a solid except possibly in the case of polar compounds. However, as a consequence of the study of radioactivity and of X-rays, we can now handle the individual atom. Our resolving power, so to speak, is very greatly increased; we begin to see the details and new classifications appear. It is obvious that the information already gathered from the new methods is but a fragment of what we may expect to learn: but we may hope that there is enough new knowledge to be exchanged profitably.

Let us set down what we have already observed. In the first place, there are very strong forces between atom and atom, molecule and molecule, which are limited in their effective range of action to distances much smaller than we have hitherto supposed; small, it may even be, compared to the distances between the centres of atoms as they lie side by side in a crystal. In non-polar compounds in which the separate molecules may be readily distinguished it appears there is the most perfect alignment of the molecules as they are fitted into their positions. A crystal of definite constitution conforms so exactly to rules respecting its angular dimensions that it seems impossible to imagine its form to be merely the result of an average of tendencies. The forces of adjustment cannot, therefore, be thought of vaguely as a force between two points each representing one of the molecules. On the contrary, it is nearer the truth to think that the adjustment is made so as to bring together certain points on one molecule and certain points on the other. The electrostatic attraction of two charged spheres is far from a perfect analogy; we should imagine rather two members of a girder structure being adjusted until the rivet holes are in true alignment so that the rivets can be dropped into their places. The action of one molecule on another depends on their relative orientations and mode of presentment to each other.

We see this well in the case of the organic crystals. The molecule is generally a very complicated structure, of most irregular but constant form. Molecule is attached to molecule in the building of the structure just as girders in a bridge are joined up to form an empty framework. In most cases the crystal contains molecules which are the image of each other in certain planes, or are derived from one another by rotation round some axis, and the arrangement of the molecules gives certain symmetries to the structure. The influence of a molecule exerted in these ways does not extend beyond its neighbours. A molecule may, of course, so affect an immediate neighbour as to influence the position of the next but one, but the action resembles that of the links in a chain.

A simple example may be given. Muller and Shearer have lately measured the thickness of the ultimate flakes of some of the fatty acids and their esters. Measurement of the thickness depends on the fact that when the substances are melted on to glass or mica the flakes form innumerable layers of equal thickness lying on one another, and the crystal, so formed, can then be examined by X-rays. The thickness is found to increase uniformly with the number of carbon links in the chain; and it may be assumed that the thickness is either the exact length or a constant factor of it. Each addition is made in complete independence of the previous length, as if the only thing that mattered was the nature of the attachment of one carbon atom to the next. There is no influence of the ends upon the atoms in the middle. Muller and Shearer also find that the constant increase in thickness of film due to the addition of a carbon atom is different on the two sides of the double-bonded oxygen; but neither side is affected in any way by addition on the other. The successive layers of the acids lie on one another with alternate orientations like a pack of cards arranged in pairs facing each other; whilst the arrangement of the esters resembles that of the ordinary pack. The local smothering of the hydroxyl group has completely altered the arrangement.

Location of action is also found in the atoms, especially the carbon atom. In fact, it is largely due to the latter that such multiplicity and exactness of form is to be found in the organic molecules. The peculiarity of the molecules are all derived from the peculiarities of the atom. In the crystal the atom is attached to three neighbours on one side by bonds differing from those which attach it to its three neighbours on the other. The forces are different at different parts of the atomic surface.

In the molecule there are not only centres of force in different parts, but the strength and probably the natures vary from place to place. The cleavage plane of a crystal, of course, cuts across the weakest bonds. In the chain molecules the monomolecular film grows by the side-to-side attachments of the molecules: and the forces that bind layer to carbon are far feebler: the film will grow more readily than the crystal.

The nature of these forces and their typical differences have, of course, been the subject of much recent study. There is, in the first place, the effect known as electron sharing, which leads to strong and directed attachment and is particularly responsible for the localisation effect. Whatever may be its nature, there is no doubt as to its importance.

Next, there are actions of a different and generally weaker type which are manifested in the binding of molecule to molecule in a crystal; and of atom to atom, as, for example, in sulphur. We may be sure that they are present in metals and alloys. The structure of a metal like aluminium may be likened to that of a polar crystal such as rocksalt, in which the sodium atoms are comparable with those of aluminium and the chlorine atom with electrons. But this is probably far from the whole truth; there is action between the aluminium atoms which are in contact. It would be difficult to explain the variety in form and properties of the various pure metals if they were to be thought of only as a mass of positive spheres and negative point charges.

Lastly, there are the pure electrostatic central actions which are manifested in particular when atoms have become like the atoms of the idle gases either through the addition or subtraction of electrons. In these cases, the action is not localised in a particular spot on the surface or a particular direction from the centre of the molecule. The action is an all-round attraction, a positive charge attracting any amount of negative charges, and *vice versa*, so that crystal structures containing these effects are full of instances of so-called co-ordination. In fact, we may well think of the co-ordination cases studied in chemistry as survivors of the general break-up of a polar crystal. In the case of the polar crystal, it is possible to calculate the effect of the electrostatic forces with some degree of success. For every molecule there is, therefore, some most satisfactory way of attachment to its like, whether similarly oriented or reflected or rotated. Whether or not this arrangement comes about during the formation of a crystal from either a liquid or a gaseous medium, must be a matter of time and environment. Molecule lines up with molecule and the crystal grows ; but there may be great differences in the ease with which molecules slip into their places. Indeed, there is ample evidence of this in the different rates of growth of the faces of any one crystal, showing that attachment is made more readily at one point of a molecule than another. The element of time may possibly come in because a molecule may come nearly into its right place and be held there sufficiently long to get settled in by thermal agitation or otherwise ; if it receives a shock from another molecule before it is settled it may be moved away altogether. It is possible to hazard something as to the formation of a colloidal particle. After all, the same forces that build the crystal build the colloid; we should naturally ascribe the latter to an irregular or incomplete action. We may suppose that the formation of the crystal begins correctly enough, but that errors of adjustment creep in until at last the growth is stopped because fresh molecules cannot find their proper places to fit into. We know that colloidal gold is crystalline in bulk ; it can only be the surface of the colloidal particle that has gone wrong. Possibly the errors are cumulative and end in the production of some feature common to the whole surface such as an actual distribution of electrical charge, or some characteristic which draws to itself ions of a given sign ; so that the colloidal particle becomes charged to an extent depending partly on itself and partly on its surroundings. The twinning of crystals is a regular example of this irregularity. The "active points," as Langmuir termed them, are so distributed over the surface already formed that there is more than one way in which fresh molecules can fit into them ; and once they begin to take up a new way they persist in it. This explanation, though not perfect, must be close to the truth.

These illustrations show that we have a broad and soundly based hypothesis on which to rest explanations of all the phenomena that can be classed under the term "cohesion," even though our present understanding of it is imperfect. We have some guide as to our interpretation of results ; and also hints as to how to proceed in our researches. For example, the crystal as a whole is simply the extension by multiplication of the crystal unit. If we examine the various properties of a crystal whose structure we know, we do at least reduce the infinite complexity of which we spoke at first ; and we may look forward to a knowledge of the active forces localised at various points of the atom and the molecule. Our aim is to substitute this particular and detailed knowledge for our previous rough approximation.

It should not be imagined that the considerations outlined above are in any way antagonistic to the ideas of the internal structure of the atom developed by Rutherford, Bohr and others : there is no conflict between a static and a dynamic view. The points of view are so far apart, and the region which they overlook is so vast, that they cannot be used as yet to correct or support each other to any useful extent. For that we have to wait, but in confidence.

Contribution by Dr. W. Rosenhain, F.R.S.

Thanks to the light which X-ray analysis has thrown on the inner structure of crystals, and the combination of this information with the detailed knowledge of the nature of metals and alloys, obtained by years of metallurgical research, it has become possible to formulate the foundation for a general theory of the nature of alloys. This theory has already furnished surprisingly simple and exact explanations of a large range of phenomena in alloys, so that its fundamental principles may well claim careful consideration—some of them, indeed, can be regarded as experimentally established.

The first of these principles is that when an alloy is formed which is of the nature known as a "solid solution," it consists of the atoms of the two metals built up on a single space-lattice—the atoms of the "solute," in fact, simply take the places of a corresponding number of atoms of the solvent metal, the lattice remaining essentially that of the solvent metal. There is, however, a certain amount of distortion wherever a "stranger" atom is present, and this distortion, which may vary widely both in sign and amount, is responsible for many of the properties of the material.

The second principle may be termed the "law of the limiting parameter" or inter-atomic distance across which the forces responsible for inter-atomic cohesion can act to any appreciable extent. This distance is strictly limited ; if it is increased by any means—as by thermal expansion, by mechanical stress, or by the introduction of stranger atoms—then a limit is soon reached at which the lattice breaks down somewhat suddenly, with the formation of another phase, which may be a liquid or a different lattice. On heating, such a change is simply melting, on straining it is the break-down of elastic behaviour which is known to be accompanied by phase-change, and on alloying with increasing amounts of another metal, the limit of solid solubility results, at a certain point, in the formation of crystals of a new type. From the view point of the nature of the bond which unites atoms in such crystals—what might be termed the "cohesion bond"—this limiting inter-atomic distance is of very great importance.

In many metals cohesion phenomena are, to some extent, complicated by the occurrence of intra-crystalline slip. When such crystals are stressed they do not break but undergo plastic deformation by a process of slip along certain planes within the crystals. Here the atoms which are attached to each other across any surface of slip must be separated, but it is not complete separation as in actual fracture, but a rapid exchange of partners. In such a slip, atoms must pass over one another by many thousands, yet continuity of "bonding" is not lost. At the same time the atoms are to a considerable extent torn from their crystalline arrangement and left in a more or less irregularly arranged condition. This condition of irregular bonding will be referred to later. One point in regard to ductility and the slip phenomena on which it depends, however, should be mentioned. The whole phenomenon is confined to metals crystallising in the two most symmetrical systems: in these alone do we find crystal planes in which the distribution of atoms is sufficiently uniform to allow of the "passing on" of bonds from atom to atom without complete loss of continuity. This explains the striking fact that well-defined inter-metallic compounds are always exceedingly brittle, as also are most inorganic salt crystals and crystals of metals like bismuth and antimony.

The mechanism of ductility by means of slip is intimately connected with another important phenomenon—that of diffusion in solid crystals. The mechanism of diffusion is suggested to be that of movement or "slip" of atoms in rows. These rows need not extend throughout even a single crystal, but may be arranged so as to form continuous circuits of no great length. No great amount of stress is required to bring about slip even on a large scale in metals at the relatively high temperatures where diffusion is rapid, and the requisite stress to bring about such diffusion-slip is provided by the lattice distortion arising from a concentration of stranger or solute atoms in a solid solution of non-uniform concentration. Thus, since the mechanism of diffusion is essentially the same as that of ductility, we should expect ductile materials to allow of easy diffusion, whilst it cannot occur readily, if at all, in brittle crystals. Inorganic salts show no appreciable diffusion until quite near the melting point, and the same applies to brittle metals like antimony and bismuth. Further, a strange or solute atom should diffuse the more rapidly the greater the local distortion it produces in the lattice. An atom very similar to that of the solute should only diffuse very slowly and—if sufficiently similar—not at all. Nickel and copper—two very similar atoms—exhibit extremely slow diffusion as compared with zinc and copper, and recently von Hevesey has shown that the radioactive isotope of lead will not diffuse into the non-radioactive isotope. In this latter case, the two kinds of atoms are so nearly identical that no lattice distortion is set up and hence there is no stress to set the rows of atoms in motion. Were diffusion a phenomenon of a "kinetic" nature, and a constant interchange of atoms took place, these phenomena would not occur.

So far the cohesion of crystalline matter alone has been considered, but non-crystalline matter is also of great interest and importance. If we apply the principle of the "limiting parameter" or inter-atomic distance at which inter-atomic cohesion can become effective, it is perhaps possible to arrive at a picture of the inner structure of an amorphous solid or "congealed" liquid which helps to explain some of the facts of the behaviour of such substances. When a liquid—supposed non-atomic for simplicity—cools down, at or near the freezing-point, the atoms approach one another within the limiting atomic range and adhesions are formed. If the liquid is sufficiently mobile, the type of crystal to be formed sufficiently simple, and the rate of cooling sufficiently slow, these adhesions become grouped into a crystal lattice and crystallisation takes place. In other circumstances, however, this does not occur, and the atoms merely form groups increasing in size with falling temperature, in which the atoms are connected together in an irregular manner; as a rule, any individual atom will be attached, in such an arrangement, to a smaller number of other atoms than in a crystal, so that the packing would be less close. The existence of these relatively large groups of atoms, though still allowing some mobility to the substance, will give it a very much higher viscosity than that of the truly molten, monatomic liquid. With falling temperature and increasing size of bonded groups of atoms, the viscosity will rise rapidly until at last a stage is reached when the groups become so large that, in effect, the whole mass can be regarded as bonded together. In such a state some of the atoms will be attached to neighbours by a considerable number of "bonds," and at the other end of the range we shall have some atoms held only by one or two of their possible means of attachment. If, now, stress be applied to such a body, what will happen? There will be no possibility of plastic deformation by slip, since the slip mechanism does not exist, but three types or stages of deformation will be possible. The first is purely elastic, the inter-atomic attachment being stretched but not broken and contracting again so soon as the stress is removed. On the other hand, there will be some atoms which are held to their neighbours at a distance just below the limiting distance referred to above, and these —if the body is stretched—will break away from at least one of their attachments, although this may only occur in the course of time. Further, where an atom has thus broken away, extra stress will be thrown upon its neighbours, so that the process may spread for a time. When the stress is released, however, these added local elastic strains will tend to work out, with the result that the atoms which had been pulled slightly out of their original position by the breaking of an attachment, will be gradually pushed back again. We have here a rough picture of the mechanism of the visco-elastic behaviour of vitreous and other amorphous materials. If a still higher stress is employed, some of the atoms, if suitably placed, may be moved bodily, by the rupture, either simultaneously, or one at a time, of all their bonds or attachments, into a new position or equilibrium. Such a movement will not throw increased stress on neighbouring atoms, but will rather tend to relieve the existing strains. The movement, therefore, will not be reversible and will have all the character of truly viscous flow. This phenomenon is also well known in vitreous bodies, but it differs widely from viscous flow in true liquids, since a stress of a definite amount is required to initiate it. In very hard and severely undercooled liquids, such a stress may suffice to cause rupture, so that in such materials viscous flow will not occur at all unless the temperature is raised. This crude picture of the constitution of an amorphous solid thus appears to fit the facts fairly well in a general way; it is also consistent with what we know of inter-atomic relationships in crystals, but beyond that it cannot at present be extended.

The nature of an amorphous or vitreous solid is of special interest in regard to the cohesion of solid metals, since there we have to consider not only the cohesion within the crystals, but of one crystal to another. There appear to be three theoretically possible ways in which two atomic lattices, growing towards one another, can adhere to one another. They may, in the first instance, be so formed that certain atoms are common to both lattices. With two systems meeting at any haphazard angle, in space, the number of atoms which can possibly fit on to both lattices without undue distortion can only be very small. Were this so, we should expect to find the junction of crystal to crystal a region of weakness; in actual fact, it is the strongest part of a crystal aggregate. Metals, when forcibly broken, always break through the crystals and not along the crystal junctions. A second possibility is the formation of a zone of intermediate orientation, the one lattice being gradually bent over into the orientation of the other. This is not possible if we maintain the principle of the "limiting parameter," since the radius of curvature of the intermediate orientation could only be very small so that the width of the zone of intermediate orientation would be comparable with the size of the adjacent crystals—and this is certainly not the case. The remaining possibility is that the gap between two adjacent lattices is bridged by a region of irregularly arranged atoms, constituting, in fact, a layer of amorphous material. Many experimental facts can be readily explained by such a structure, among them the fact that whereas a wire made of a crystal aggregate displays a behaviour under stress which requires the presence of some viscous or at least visco-elastic material, a wire made of a single crystal does not.

Finally, it is desirable to notice that the kind of atomic "bonding" to which reference has hitherto been made—what may be provisionally termed "cohesion bonding"—is by no means the only form of attachment between atoms. In a solid solution, we have to deal solely with bonding of this kind, and, correspondingly, we find that the inter-atomic distances, although varying by a few per cent., are roughly constant. When we come to well-defined inter-metallic compounds, on the other hand, we find in some cases greatly reduced inter-atomic distances. Thus in aluminium, the distance between adjacent atoms is of the order of 4·3 A.U., but in the compound $CuAl_2$, aluminium atoms are found with a centre-distance of only 2·42 A.U. It is this which probably constitutes the real difference between a compound and a solid solution; the nature of the inter-atomic bonding must be very different in the compound and can, perhaps, only occur under the influence of some or more atoms of a different kind whose juxtaposition allows of a serious re-arrangement of the atomic electron-shells. The properties of the two kinds of bodies are correspondingly different, notably in regard to ductility, diffusion, and the formation of solid solutions.

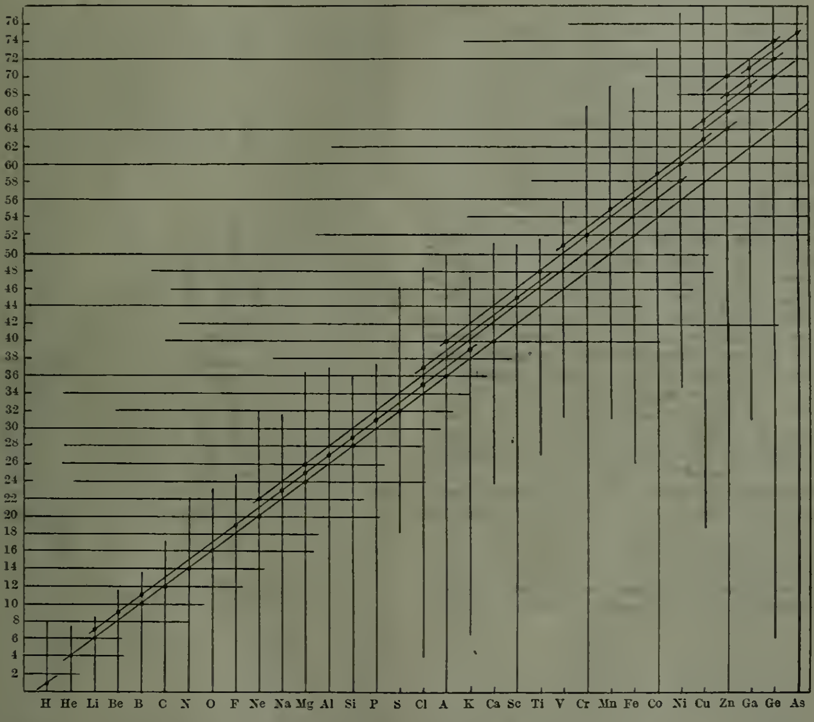
Enough has, perhaps, been said to indicate how the application of results obtained by means of X-ray analysis to the wide range of facts elicited by metallurgical research can hope to throw new light both on the nature of cohesion and on the properties of metals.

NEW DEPOSIT OF SOAPSTONE IN AUSTRIA

It is reported that an enormous deposit of soapstone has been discovered in Zwettl, not far from the Bohemian frontier. The soapstone, which is stated to require very little preparation, can not only be cut, sawn, drilled and polished, but will absorb many colours, a property that should lead to its extensive use in powder form in the colour industry. The deposit is the most important of its kind yet discovered in Central Europe.

ISOTOPES

At Liverpool Dr. F. W. Aston announced to the British Association that he had measured the masses of the isotopes or atoms of a number of elements in addition to those already published. The method adopted was a new one, the details of which were given; the most important results are that scandium is simple with an atomic weight of 45, titanium is simple with an atomic weight of 48, vanadium is simple with an atomic weight of 51, chromium is simple with an atomic weight of 52, manganese is simple with an atomic weight of 55, cobalt is simple with an atomic weight of 59, gallium has two isotopes of masses 69 and 71, germanium has three isotopes of masses 74, 72 and 70, strontium is simple with an atomic weight of 88, yttrium is simple with an atomic weight of 89 and silver has two isotopes of masses 107 and 109. The atomic weights or masses of the first forty elements and a few others are now known and some of these results are shown in the accompanying diagram. It is interesting to note that with the exception of nitrogen the odd elements have odd weights or masses and that with the exception of hydrogen no atomic weight is less than twice the atomic number. A study of such a diagram promotes speculation as to the relationship of the elements which each reader can pursue as he feels inclined, unbiassed, broadly speaking, by any experimental evidence.



In this diagram the vertical lines show the masses of the atoms or isotopes and the elements are placed in the order of their atomic numbers or places in the periodic table. It is interesting to note that lithium, boron, carbon, nitrogen, oxygen, neon, magnesium, silicon, sulphur, argon and calcium all have atoms or isotopes whose mass is twice the atomic number. When we come to elements with higher atomic weights the masses exceed twice the atomic number and the excess becomes greater as we proceed along the periodic table but in an irregular manner which does not appear, so far, to have been reduced to any defined law. Additional determinations are awaited with much curiosity, and no doubt the new method employed by Dr. Aston will produce a considerable number of accurate measurements.

NEW ZEALAND MINERAL OILS

By Prof. THOMAS H. EASTERFIELD, M.A., Ph.D., and NORMAN McCLELLAND.

Many attempts have been made to establish mineral-oil industries in New Zealand, and though the results have so far been disappointing, much has been learned, and it is probable that success will eventually result.

Three classes of oils have, up to the present, been manufactured. These are :—

1. Kauri oil, by the distillation of peat from the kauri-gum lands of the Auckland Province (North Island).
2. Shale oil, by the distillation of bituminous shales in the Southland District (South Island).
3. Petroleum, by direct boring.

1. The production of kauri oil is of comparatively recent development; it is stated that there is an almost unlimited quantity of raw material, yielding nearly 40 gallons of oil per ton of peat. The oil appears to consist largely of the products of cracking of kauri gum, distributed in a finely divided condition through the peat, and to be as complex a mixture as crude rosin oil. As it is understood that work upon this oil is being carried out at Auckland University College, it is not proposed to deal further with it in this paper.

2. A very large field of oil shale exists at Orepuki in Southland, there being evidence that not less than 1,000,000 tons is in sight on the property of one company alone. The shale consists of a bed 4–5 ft. thick, with a rotten roof and a substratum of coal varying from 12 to 20 ft. in thickness.

The New Zealand Coal and Oil Company erected a works on this property in 1899, with an installation of 20 continuous Scotch retorts, together with the usual accessory apparatus. The mine and works were closed down in 1903, after 14,400 tons of shale had been brought to the pithead and a Government bonus of £5000 had been received for the first 100,000 gallons of crude oil produced in New Zealand. The shale yields about 38 gallons of oil and 19 lb. of ammonium sulphate to the ton, together with sufficient gas for heating the retorts.

The crude oil, obtained by a large-scale distillation test, was reported on by Sir Boverton Redwood in 1906. It gave :—

	Per cent.
Burning oil	25·9
Gas oil	3·1
Medium oil	4·0
Lubricating oil	17·6
Hard paraffin	19·0
Soft paraffin	1·1

A similar shale is found at Waikaia, also in the Southland District, but at a considerable distance from Orepuki. Experiments conducted in the Dominion Laboratory (Maclaurin, *Dominion Laboratory Report*, 1912, p. 11) show that the shale is remarkably like that at Orepuki both in composition and yield of oil. The crude oil from Orepuki contains 1·79 per cent., and that from Waikaia 1·9 per cent. of sulphur.

It should, perhaps, be mentioned that the value of the ammonia to the New Zealand shale-oil industry is largely discounted by the fact that the price of sulphuric acid for sulphate making is much higher in New Zealand than in Scotland. A high price for sulphuric acid must also react unfavourably upon the purification processes.

3. Natural mineral oil has been discovered in small quantities in many localities, and boring has been more or less energetically carried out at New Plymouth (west coast of North Island), Kotuku (West Coast, South Island), Dannevirke and Gisborne (east coast of North Island). New Plymouth is the only locality where a considerable flow of oil has at any time been observed, and, even at this centre, the yield has not justified the high hopes at one time entertained.

The following values have been obtained by distilling the oils from these places :—

	New Plymouth, 1906	New Plymouth, 1914	Kotuku (West Coast)	Maruia (Nelson District)	*Waitangi (Gisborne), 850 ft.	†Waiotapu (Auckland)
Sp. gr. of crude oil at 15·5° C.	0·84	0·845	0·886	0·933		0·809
Benzine boiling up to 150°	20 per cent. Sp. gr. 0·764	5·5 per cent. Sp. gr. 0·787	3·8 per cent. Sp. gr. 0·76	Approx. 2 per cent.	25 per cent. Sp. gr. 0·749	Nil.
Kerosene boiling 150°–300°	40 per cent. Sp. gr. 0·82	50·5 per cent. Sp. gr. 0·838	42 per cent. Sp. gr. 0·84	35 per cent. Sp. gr. 0·94	42 per cent. Sp. gr. 0·831	6 per cent.
Oil boiling 300°–400°	37 per cent.	25·5 per cent.	47 per cent.	57 per cent.	28 per cent.	300°–360° 94 per cent.
Paraffin wax in above	13 per cent.	12 per cent.	Trace	Trace	2·2 per cent.	12 per cent.
Residue (pitch)	2 per cent.	1·5 per cent.	5·0 per cent.	6 per cent.		
Contraction of benzine on sulphonation		36 per cent.	5·0 per cent.			
Contraction of kerosene on sulphonation		30 per cent.	32 per cent.	24 per cent.		

The kerosene from all these petroleums is optically inactive. (Those from Waitangi and Waiotapu have not been examined.)

* From report by Dr. Maclaurin, Dominion Analyst, 1920, p. 34.

† ,, ,, ,, ,, ,, ,, ,, 1922, p. 37.

In the neighbourhood of New Plymouth several companies have erected derricks, and probably £150,000 has been spent in borings—a small sum in comparison with that spent in other oil fields before success was finally attained. In 1906 a very promising flow was obtained on the property of the Taranaki Oil Wells, Ltd., at New Plymouth, one well yielding over 250,000 gallons, and a modern refinery was erected to deal with the oil. The operations of this company were stopped owing to the failure of casings in their wells, after a bonus of £10,000 had been obtained from the New Zealand Government for the production of the first 1,000,000 gallons of crude petroleum and a further bonus of £2500 for the production of 250,000 gallons of refined oil. The best flow of oil was said to be obtained at about 2300 ft.

The following description of the oil and its constituents may not be without interest. The oil, though liquid as it runs from the bore, sets to a semi-solid grease owing to the large quantity of solid paraffin dissolved in it. It is practically free from sulphur and from acid and basic constituents. The gravity of the various distillates is higher than that of the distillates of similar boiling point usually found in commerce. The smell of the crude distillates is less unpleasant than that of many of the commercial oils; and even higher boiling fractions show remarkably little colour or evidence of cracking, the fraction boiling at 300°–360° being only light yellow in colour. The benzine and kerosene, however, burn with a smoky flame, so that the kerosene cannot be used in an ordinary kerosene lamp; this is due to the presence of benzenoid and similar hydrocarbons. The benzine fraction reacts but slowly with bromine, showing that olefines are practically absent. On the other hand, the contraction on shaking with fuming sulphuric acid is no less than 36 per cent. with the benzine and 30 per cent. in the case of the kerosene.

After this treatment the kerosene is water-white and burns without any trace of smokiness. The gravities of the benzine and kerosene thus treated are still high in comparison with Pennsylvanian oils of similar boiling point, indicating that the residues are rich in cycloparaffins, of which, indeed, they are chiefly composed. The oil is thus in general characters similar to that from the Koetei District of Burma, described by Jones and Wootton (*J.C.S.*, 1907, **91**, 1146), and the further examination of the actual constituents of the oil confirms this conclusion.

It is not without interest that the Taranaki oil field is within 20 miles of Mt. Egmont, an extinct volcano, suggesting that the benzenoid and cycloparaffin hydrocarbons owe their origin to thermal action.

The results of the examination of the oil are given below :—

1 Cycloparaffins

The benzine fraction, after shaking with fuming sulphuric acid until no further contraction occurred, was washed with alkali and water, dried, and then repeatedly fractionated through a column similar to that described by Dufton (*J.S.C.I.*, 1919, 45), when the following hydrocarbons were isolated :—

Fraction.	Boiling point	Sp. gr. 15·5° C.	Cycloparaffin	Constants given in literature	
i	69°–74°	0·7494	Methyl cyclopentane	B.p. 72°	Sp. gr. 0·7474 (21°) (Markownikoff)
ii	78°–83°	0·7790	Cyclohexane	B.p. 81°	Sp. gr. 0·7788 $\left(\frac{19^\circ}{5^\circ}\right)$ „
iii	100°–104°	0·7669	Methyl cyclohexane	B.p. 103°	Sp. gr. 0·7662 „
iv	115°–125°	0·7433	Probably a mixture of *n* octane (b.p. 125°, sp. gr. 0·719) and dimethyl cyclohexanes (b.p. 120°, 125°, sp. gr. 0·8)		
vi	160°–163°	0·7884	α-Decanaphthene	B.p. 159°–165° (Subkow)	Sp. gr. 0·783 at 15° (Markownikoff)
vii	179°–182°	0·7987	Undecanaphthene	B.p. 179°–181°	Sp. gr. 0·8119 „
viii	196°–198°	0·8042	Dodecanaphthene	B.p. 196°–197°	Sp. gr. 0·8055 (16°) „

From fraction v *n*-nonane was isolated, b.p. 146°–152° (mainly at 150°), sp. gr. 0·7243; the literature gives b.p. 149·5°; sp. gr. 0·7228 (13°), 0·7177 (20°).

2 Benzenoid Constituents

On careful fractionation of the original benzine, the following results were obtained :—

		Per cent.
i	Boiling below 90°	5·0
ii	„ between 90°–110°	30·0
iii	„ „ 110°–140°	47·4
iv	„ „ 140°–170°	17·6

In a preliminary experiment toluene was recognised in the second fraction by shaking with fuming sulphuric acid until no further contraction occurred, and diluting the separated acid, when a sulphonic acid crystallised out that proved to be *p*-toluenesulphonic acid of melting point 92° (Norten and Otten, *Amer. Chem. J.*, **10**, 140).

Benzene, toluene and xylene were identified in fraction ii by shaking with sulphuric acid, removing volatile hydrocarbons from the acid layer by means of a current of air, and then hydrolysing the sulphonic acids by steam distillation at a temperature above 160° (Armstrong and Miller, *J.C.S.*, 1884, **45**, 151). The regenerated hydrocarbons were then carefully fractionated :—

	Per cent.
Original contraction on shaking with sulphuric acid	23·7
Volume regenerated by steam distillation	19·6

The regenerated hydrocarbon gave :—

	Per cent.
Benzene, b.p. 80°–81°, sp. gr. 15·5°, 0·8802	9
Toluene, b.p. 111°, sp. gr. 15·5°, 0·8697..	68
Crude xylenes, b.p. 120°–145°	17
Residue boiling above 145°	5

The benzene was further identified by conversion into *m*-dinitrobenzene m.p. 89·5° ; the toluene by conversion to 2.4 dinitrotoluene m.p. 70·5°, and by oxidation to benzoic acid m.p. 121°.

The crude xylenes contained the *ortho*, *meta* and *para* isomers, as on oxidation the three benzene dicarboxylic acids were formed. The least soluble acid was identified as terephthalic acid by its dimethyl ester m.p. 140° ; isophthalic acid by its dimethyl ester melting at 64° ; phthalic acid by the fluoresceïn reaction.

Toluene and xylene were also found in the fraction of the benzine boiling at 110°–140° By fractionation of the hydrocarbon regenerated from the sulphuric acid extract of fraction iv (b.p. 140°–170°), mesitylene and pseudocumene were separated ; they were identified by conversion into trinitro derivatives melting respectively at 235° and 184°.

Naphthalene and methylnaphthalenes were isolated from the kerosene b.p. 150°–300°. On adding picric acid to the fraction boiling at 210°–220°, a dense precipitate of a bright yellow colour was formed. After recrystallisation it melted at 150°, the melting point of naphthalene picrate. Steam distillation after the addition of alkali yielded pure naphthalene melting at 80°. From the fraction 235°–245° picric acid precipitated a picrate of a deeper yellow colour ; after repeated crystallisation from alcohol it melted at 116°, the correct melting point for α-methylnaphthalene. The molecular weight found by titration was 146, calculated 142. The hydrocarbon generated from the picrate was liquid, thus confirming the view that it was the α compound.

1.4-Dimethylnaphthalene picrate was precipitated from the fraction boiling at 258°–265° in orange needles, which after recrystallisation melted at 139° ; the molecular weight found was 155, calculated 156.

A deep red picrate was precipitated from the fraction boiling at 280°–300° ; the quantity was too small for identification. It is not improbable that this was the picrate of the tetramethylnaphthalene boiling at 320° isolated by Tammann (Ger. Pat. 95,579 ; *Chem. Centralblatt*, 1898, **1**, 812).

3 The Paraffin Wax

A quantity of the paraffin wax was distilled at 6 mm. pressure, and boiled between 215° and 290°. The fractions thus obtained were repeatedly refractionated until heaping took place at certain temperatures. The fractions were finally distilled at 15 mm. and then recrystallised from alcohol, until the melting points were constant.

The following paraffins were thus shown to be present :—

	Boiling point at 15 mm.	Melting point		Paraffin
i	243°	50·9°–51·1°	$C_{24}H_{50}$	Tetracosane
ii	249°–251°	53·2°–53·4°	$C_{25}H_{52}$	Pentacosane
iii	258°–260°	56·7°	$C_{26}H_{54}$	Hexacosane
iv	272°–274°	61·5°	*$C_{28}H_{58}$	Octacosane
v	280°–282°	64·0°	$C_{29}H_{60}$	Nonacosane
vi	290°–292°	65·2°–65·4°	$C_{30}H_{62}$	Triacontane
vii	299°–303°	67·8°–68·2°	$C_{31}H_{64}$	Hentriacontane

* Heptacosane could not be detected.

The still residue boiling above 290° at 6 mm., after repeated crystallisation from alcohol and ether, melted at 72·7°–73·1° ; assuming that it contained only primary paraffins, it must have consisted chiefly of pentatriacontane m.p. 74·7°, or of still higher members of the series.

If the deductions of Francis and his coworkers (*J.C.S.*, 1922, **121**, 496, 1529, 2804), with regard to the non-identity of the hydrocarbons of paraffin wax with those obtained by synthesis, are correct, then the conclusions here arrived at may require modification.

To test the stability of paraffins at these comparatively high temperatures, paraffin wax, m.p. 57·2°–57·4°, was sealed up in an evacuated tube and heated for a week at a temperature of 350°–400°. The melting point of the wax was not altered by this treatment, showing that no decomposition had taken place.

Paraffins may therefore be slowly distilled in vacuo at the above temperatures of fractionation without fear of decomposition. Thorpe and Young (*Annalen*, 165, 1) have shown that paraffin wax distilled in closed tubes decomposes into a liquid mixture of paraffins and olefines.

The authors wish to express their thanks to Mr. G. Millar, formerly manager of the Taranaki Oil Wells, Ltd. ; to Mr. M. Ongley, N.Z. Geological Survey ; and to Mr. H. Hill, for the crude and refined oils used in the investigation ; and to Mr. P. G. Morgan, Director of the New Zealand Geological Survey, and to Mr. A. H. Kimball, Under Secretary for Mines, for supplying statistics made use of in this paper.

SUGAR-CANE FORECAST, BRITISH INDIA, 1923–24

The first general memorandum relating to 99 per cent. of the total area under sugarcane in British India, estimates the total area sown at 2,715,000 acres, as against 2,392,000 acres at the corresponding date last year, or an increase of 13 per cent. Weather conditions at the time of planting were generally favourable, and the present condition of the crop is, on the whole, good.

DINNER OF CHEMISTS,

October 31, 1923

This dinner is being held under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry at the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on October 31, at 7 for 7.30 p.m.

The details are being arranged by a committee consisting of representatives of the three societies mentioned above and one or two other societies. The price of the tickets for ladies or gentlemen is 12s. 6d. each, not including wine.

Sir William Pope, K.B.E., F.R.S., will take the chair. There will be some speeches and some music ; it is thought that both these will be of interest, and that there will be in addition opportunities for informal talk.

No similar dinner for chemists has hitherto been organised on exactly these lines, and it is expected that such a gathering will be not only very pleasant, but will be useful in promoting that social acquaintance which is so valuable in connexion with prevailing ideas and hopes. Members of any of the societies concerned are invited to attend and to bring guests, but no rigid line need be drawn in the case of chemists who would like to attend and whose membership of one of the societies has not yet been attained.

Applications for tickets should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C.2.

PERSONALIA

The Railway (Engineering) Gold Medal for 1922-23 of the Institute of Transport has been awarded to Sir Robert Hadfield, D.Sc., F.R.S.

Mr. F. B. Gorin has been appointed chief of the heavy chemical section of the chemical division of the United States Bureau of Foreign and Domestic Commerce.

* * *

With regret we record the death of Mr. W. J. Leonard, senior partner in the firm of Carless Capel and Leonard, of the Hook Chemical Works, Hackney Wick. Mr. Leonard was a well-known member of the London Section of the Society of Chemical Industry.

With regret we announce the death of the eminent French physicist Violle, a member of the "Institut" since 1881. He will be remembered chiefly for his calorimetric pyrometer and his investigations on radiation at high temperatures and on the velocity of sound.

CORRESPONDENCE

THE ORIGIN OF SYMBOLS

Sir,—With reference to "Analyst's" query in your issue of September 7, I have dipped into some old chemistry books in my possession, and find that no symbols or formulæ are given in Davy's "Agricultural Chemistry" (1814) Accum's "Brewing" (1820), Gurney's "Chemical Science" (1823), or Christison's "Poisons" (1832). On the other hand, Ure's *Dictionary of Chemistry*, 4th ed. (1831), gives Berzelius's table of equivalents with formulæ, but no other formulæ or symbols in the text.

Daubeny's "Atomic Theory" (1850), Napier's "Art of Dyeing" (1853), and Noad's "Chemical Manipulation and Analysis" (1852) all give symbols and formulæ freely, whilst Glover's "Mineral Waters" (1857) quotes many analyses but gives no formulæ.

It would therefore appear that the use of symbols and formulæ arose gradually during the period 1833-1850.—I am, Sir, etc.,

A. O. Jones

FINISH OF CHEMICAL GLASSWARE

Sir,—I have noticed a letter from Mr. Jones in your issue of September 21, with respect to the finish of various pieces of chemical apparatus as being inefficient.

This undoubtedly is a fact, as much of this lampblown apparatus is made by workers entirely ignorant of the uses to which it is ultimately put, and the difference between cheap apparatus and that slightly more expensive is shown by this attention to details.

If your correspondent would purchase his apparatus from reputable *manufacturers* who understand and advertise in this Journal, he would have no cause to complain.—I am, Sir, etc.,

A. V. Hussey

Duroglass Works,
Walthamstow, E. 17
September 21, 1923

THE STREAM-LINE FILTER

Sir,—Has Mr. Watts carried his explanation of this filter to a logical conclusion in his letter of the 18th inst. ?

Solutions of common salt, etc. after passing through the filter, are found to be more dilute than before, because "the tendency of a liquid is always to diminish its surface energy."

Where the surface tension of a solution is lower than that of the solvent, this may appear reasonable as one of the factors, but the surface tension of a 5 N NaCl solution is 83·5 dynes per cm. at 18° C., that of water being 73·6, hence one would surely expect the brine to be concentrated by the "filtration" !

Have the facts in this case been conclusively established ? Commencing with a damp pack the early runnings may include displaced moisture for some time, but is the affluent constantly different, and how is the $NaCl$ content of the solution in the inlet tubes affected ?—I am, Sir, etc.,

William C. Reynolds

NEWS AND NOTES

BRITISH INDIA

First Forecast of the Sesamum Crop, 1923-24

A memorandum based on reports received from provinces which contained an average of 99·6 per cent. of the entire area under sesamum, states that the area under the crop, so far reported, is 2,100,000 acres, as compared with 2,367,000 acres (revised) at this time last year. Sowings still continue in many places. The weather at sowing time was favourable, except in Bengal and Madras, where early rains failed. The present condition of the crop is, on the whole, fair.

SOUTH AFRICA

Prospects for a Shale-Oil Industry

An article on the oil-bearing rocks in the Union of South Africa is contributed by T. G. Trevor to the July issue of the *S. African Journal of Industries.* After discussing the chief oil-yielding beds, the author describes the nature of the crude oil obtained from them, and concludes by stating that although South Africa appears to possess extensive deposits of shale oils of good quality, the question whether exploration is economically possible is very difficult. The capital required would be relatively great and mining risks considerable, so that it would be necessary not only to work out development and assay plans similar to those required for gold mines, but to consider the cost of refining, distribution and other factors, a question now being investigated by the Oil Fuel Committee appointed by the Union Government.

CANADA

The Chemical Industry in 1921

A summary report issued by the Dominion Bureau of Statistics' Mining, Metallurgical and Chemical Branch states that owing to the general depression and the fall in prices, the value of the Canadian output of chemicals and allied products reached only $87,184,000 in 1921, compared with $121,686,000 in 1920 (*cf. J.*, 1922, 557 R). Altogether the capital of the 459 firms engaged in the industry was $116,712,000, wages and salaries paid amounting to $12,330 and $15,950,000, respectively, and the cost of raw materials was $42,440,000, so that the value added by manufacture totalled only $44,745,000 ($61,616,000 in 1921). The acid, alkali, salt and compressed gases industries had the largest capital ($34,164,000) of any of the chief groups of manufactures, and were followed by paint, pigments and varnish ($20,331,000), soap, washing compounds and toilet preparations ($16,115,000) and explosives, ammunition, fireworks and matches ($13,642,000). At the close of 1921, although prices were lower than at the beginning of the year, conditions in the chemical industry showed much improvement, and prospects were better than at any time since the close of the war.

Mineral Production, 1922-23

According to the Dominion Bureau of Statistics, the Canadian production and value of certain minerals and allied products in 1922 was as follows :—Cement, 6,447,696 barrels ($14,324,715) ; copper, 42,879,818 lb. ($5,738,177) ; gold, 1,263,364 fine oz. ($26,116,050) ; gypsum, 484,629 t. ; nickel, 17,597,123 lb. ($6,158,993) ; platinum, 469 fine oz. ($45,783) ; palladium, 724 fine oz. ($47,060) ; osmium group, 392 fine oz. ($31,360) ; and salt, 183,438 t. All show a decrease compared with 1921, except gold and salt.

The mineral production during the first six months of 1923 shows that the mining industry of Canada has recovered from the slump of the last few years. The total value of products amounted to $87,152,248, being an increase of 44 per cent. over the corresponding period last year. The gold output amounted to 530,402 fine oz., valued at $10,964,382, and the production of silver totalled 8,336,946 oz., valued at $5,506,489. The other metals all show increases in production, and increased production of non-metallic minerals, especially of asbestos, is general.

FRANCE

A New Compound Fertiliser

In the August issue of *Chimie et Industrie*, Prof. C. Matignon describes a new compound fertiliser, "Superam," prepared by utilising the acidity of superphosphate to neutralise ammonia, thereby reducing the quantity required of sulphuric acid and obtaining a well-balanced fertiliser in the form of a dry, neutral powder. Previous attempts to utilise this method have failed on account of the reversion of the superphosphate, owing to the formation of the basic phosphate in presence of ammonia and free calcium sulphate. This difficulty has been overcome by the Cie. de St. Gobain, which utilises *dilute* gaseous ammonia (3 to 5 per cent.), which combines partly with the free phosphoric acid and partly with the phosphoric acid of the monocalcium phosphate (but without affecting its assimilability) according to the equations :—

$$H_3PO_4+2NH_3=(NH_4)_2HPO_4$$

$$CaH_4(PO_4)_2+2NH_3=CaHPO_4+(NH_4)_2HPO_4.$$

Thus, if 100 kg. of superphosphate (16–18 per cent.) is acidified with 10 kg. of sulphuric acid (60°), then treated with gaseous ammonia (diluted with air, 110 kg. of "Superam" is obtained containing 4·10 per cent. N and 15·77 per cent. total P_2O_5, of which 97 per cent. is assimilable, and 76 per cent. soluble in water. In this way only 48 per cent. of the sulphuric acid is used that would be required in preparing the material for a mixture of ammonium sulphate and superphosphate. In addition the water is partly eliminated owing to the heat evolved. It is, however, essential to regulate the temperature of the reaction very carefully, for if it takes place too rapidly, the calcium sulphate will begin to cause reversion, which is easily detected by the fact that the product becomes moist, owing to the liberation of the water combined with the calcium sulphate, present partly in the form of gypsum in superphosphates.

JAPAN

The Recent Disaster and Chemical Industry

Although definite information is lacking, it appears probable (*Chem. and Met. Eng.*, Sept. 10, 1923) that the Japanese chemical industry has suffered heavy loss through the earthquake and its aftermath, as several of the largest chemical factories, producing soda, acids, potassium chlorate and quinine, are situated in the devastated area. The important arsenic and graphite industries, are, however, located in the interior and will probably be affected only by the deranged transport facilities, whilst the dyestuffs, iron and steel, copper and galvanising industries, in the Osaka and Kobe districts, are unharmed. As Kobe is the chief port of Japan, the loss of chemicals in transit and storage will be insufficient to have much influence, the main loss having probably fallen on the large stocks of silk stored in Yokohama. No estimate can be made of the effect of the disaster on the foreign chemical trade, but if there is a shortage of silk, this may stimulate the artificial fibre industries and reduce the demand for weighting salts and dyestuffs. That reconstruction is to begin at once is shown by large inquiries for iron and steel.

GERMANY

The Salt Industry in Germany

Almost inexhaustible supplies of rock salt are to be found in Germany in the district round Stassfurt and in the "salt-mines province" of Bavaria. The Stassfurt salt contains 98 to 99 per cent. of sodium chloride, whereas rock salt obtained from other German mines is of 90 per cent. purity. The Bavarian salt is obtained by flooding the mines and concentrating the brine thus formed. The works at Schoenebeck in the Magdeberg district has an average annual production of 60,000 tons and constitutes the largest single enterprise of this kind in the continent of Europe. Other important mines are situated at Egestorf, Lueneburg, Stade, Heilbronn-am-Neckar and Salzungen. For inland consumption, the salt is sold directly to the trade, but for export it is sold exclusively by the Salz-Ausfuhr Gesellschaft, Berlin. The production in 1921 comprised : rock salt, 1,876,540 metric tons ; brine salt, 317,060 t. ; panstone and waste, 6920 t. ; salt by-products, 81,780 t. ; figures which compare with 1,332,180 t., 678,770 t., 107,110 t., and 105,560 t., respectively, in 1913. The decline in the production of by-products and brine salt is ascribed to the shortage of coal. Since April 1, 1923, the rock salt producers in Germany been combined to form the Steinsalz-Syndikat G.m.b.H., Berlin, which replaces the former convention.

REVIEWS

QUALITATIVE ORGANIC ANALYSIS. AN ELEMENTARY COURSE IN THE IDENTIFICATION OF ORGANIC COMPOUNDS. *By* OLIVER KAMM. *Pp. vii*+260. *New York*: *John Wiley and Sons, Inc.*; *London*: *Chapman and Hall, Ltd.*, 1923. *Price* 12*s*. 6*d*. *net*.

The systematised identification of organic compounds as a discipline is a comparatively new subject which has received more attention in America than in Europe. In Gattermann's well-known *Praxis des organischen Chemikers* the preparation of many representative compounds is followed by a description and discussion of their characteristic reactions, but the analytical part is confined to qualitative and quantitative elementary analysis. Cohen's *Practical Organic Chemistry*, an English textbook, deals briefly with the systematic identification of organic compounds, much useful information being crowded into the space of eight pages; the determination of molecular weight is also described.

In the book under review the author presents an analytical scheme developed by him whilst engaged in teaching the subject in the University of Illinois. The book is intended for college tuition; its tone is didactic throughout, and the text interspersed with problems and questions in small type. The text-matter comprises three sections :—(1) Theoretical part (106 pages) on solubility behaviour and classification reactions; (2) laboratory directions (79 pages) for the identification of compounds and the examination of mixtures; (3) classified tables of about 2000 compounds, including practically all those procurable on the market, with the exception chiefly of salts and dyes (54 pages). The classification is based on division into solubility groups and further division of each group into sub-groups of compounds of like chemical behaviour (*e.g.*, alcohols, ketones, amides, etc.); the liquid compounds are arranged in the order of increasing boiling-points, the solids in the order of increasing melting-points. The tables are intended for preliminary aid before proceeding to more advanced reference books.

The systematic identification procedure consists in physical examination, determination of constants, elementary analysis, solubility tests, homologous tests, consultation of literature, and preparation of derivatives. The preface states that "the most radical individual departure from other analytical schemes consists in the subdivision of organic compounds into seven solubility groups." It may be of interest here to give a list of these groups :—(*A*) Soluble in water: (1) soluble; (2) insoluble in ether. (*B*) Insoluble in water: (3) soluble in dilute hydrochloric acid; (4) soluble in dilute caustic soda; (5) soluble; (6) insoluble, in cold strong sulphuric acid; (7) other indifferent compounds containing nitrogen, sulphur, etc.

Not having put the book to the test of practical experience (by which alone any imperfections could be detected), the reviewer does not feel called upon to criticise a system of procedure so obviously the fruit of several years' patient experimental and tutorial work; but a careful perusal of the book leaves him with the conviction that it will prove a thoroughly reliable, as well as stimulating, guide to the student of organic analysis.

There are but few typographical errors in the text (*e.g.*, "biruet" for "biuret," in p. 91). "Affected" instead of "effected" (pp. 181, 182) is an irritating misspelling, peculiar to American technical literature.

W. R. SCHOELLER

VARNISHES: THEIR CHEMISTRY AND MANUFACTURE. *By* CH. COFFIGNIER. *English translation by* DR. A. H. J. KEANE. *Pp. viii*+547. *London*: *Scott Greenwood and Son*. 1923. *Price* 21*s*.

The original work (*Les Vernis*. By Ch. Coffignier. Preface by M. Haller. Encyclopédie de Chimie Industrielle. Pp. xviii+640. Paris: J. B. Baillière et Fils, 1921. Price 40 francs) was reviewed at length by the late Dr. Ingle (*cf*. *J*., 1921, 243R), who laid stress on its value compared with English or German books on the subject.

The publishers state that the book is a translation and not an English edition. The original has been faithfully followed, even where French practice in varnish-making differs from English methods. The book thus amplifies without supplanting the existing English literature on the subject. In accordance with the above statement the translation has been faithfully carried out, the index has been entirely rearranged and a table of contents inserted at the beginning, which is a great advantage. The preface by M. Haller is omitted in the English translation. The volume is a valuable addition to publications in English relating to the varnish industry, and the publishers are to be congratulated on a volume of smart appearance and of good type; moreover, at a very moderate price. Dr. Ingle has reviewed the book so fully that additional criticisms will be few. The translator might have used his discretion in correcting many obvious mistakes in the original work, especially where the names of English authors are concerned—*e.g.*, A. H. Salvay not M. H. Salvary, Wilkins for Wilking; even the error in the formula of linolenic acid ($C_{28}H_{32}O_2$) might have been eliminated. There are a number of errors in the letterpress which have been overlooked—*e.g.*, angolacopal resene cannot have the formula $C_{30}N_{54}O_6$, nor tetrachlorethane the name ethanium tetrachloride.

In the mass of detail presented in the volume it is exceedingly difficult to avoid errors, which remain even after careful proof-reading. It is occasionally apparent that the translator is not familiar with English trade terms. On pages 435-437 many of the French terms used to describe the defects of varnishes are translated literally, whereas it would have been better to have given the English equivalents. No mention is made of the common defect "bloom," which is rendered as "clouding." Often the translation from French to English is too literal, and although correct, is lacking in style and meaning. A great defect in the original work is the very inadequate reference to contributions by non-French authors to the knowledge of the subject. If the translator had inserted references to the Abstracts of the Society of Chemical Industry in addition to the French references, the English reader would have been grateful. It is much to be regretted that so little information is given of the manufacture and properties of wood oil varnishes. All interested in the industry will thank Ch. Coffignier for his valuable work and Messrs. Scott Greenwood and Son for publishing the English translation. It is to be hoped that the numerous small errors will disappear in the second edition and that the subject will then be treated fully from an international standpoint.

BY-PRODUCT COKING. *By the late* G. STANLEY COOPER, B.Sc. *Second edition revised by* E. M. MYERS. *Pp. xv* + 188. *London: Benn Bros., Ltd.*, 1923. *Price* 12*s.* 6*d.*

The volume is intended as a guide to those connected with the practice of coke-oven and by-product recovery plants. It is a very concise manual, including, as far as space will allow, detailed descriptions of the various processes and plant involved. The industry, being yet in its infancy, has made great advances within the past few years, and a revision of the earlier edition is assured of a cordial reception. The first three chapters deal with the evolution of the industry, and the classification and preparation of coals for carbonisation, the brevity of which is very marked. Much of our present knowledge of coking and non-coking coals, and their classification has been obtained within the past nine years, and it is regrettable that no mention is made of the recent valuable work of Lessing, Beilby, Illingworth, Stopes, Wheeler, Sinnatt and others on this subject. Chapter IV is essentially practical, dealing with the manipulation of the ovens, and concludes with a list of valuable hints for the practical worker. The following two chapters consist of detailed descriptions of the more modern types of ovens, and coal and coke handling machinery, forming a valuable collection of the descriptive pamphlets issued by all the most important makers of such plant, the whole having been carefully edited and modified by suggestions based upon the author's own experience. In the chapter dealing with the formation and recovery of tar and ammonia, one would have expected to find reference to the recent valuable work of Hodsman and Foxwell on the formation and dissociation of ammonia in the oven, but this has obviously been overlooked. Mention is made of the modern tendency to neutralise, dry, and crush the sulphate of ammonia, but no description is given of the various methods in use. In describing the utilisation of surplus gas the following paragraph appears, as in the previous edition :—"The use of coke-oven gas for town lighting has not developed to any great extent in this country." Whilst this was true nine years ago, it is a very pessimistic view to take of the present practice, since most of our cities and towns, in the vicinity of coke-oven plants are now taking, or seriously contemplating taking the gas for this purpose, *e.g.*, Leeds, Sheffield, Middlesbrough, Birmingham, and many other smaller towns, some relying entirely upon this source for their supply. An excellent description is included of the fundamental considerations controlling the processes of benzol recovery and rectification, tar distillation and the working-up of the various fractions, and the various types of plant commonly met with. Chapter XII is devoted to chemical tests for the control of such processes, and chapter XIII to the future development of the industry. In the latter is found a brief paragraph describing the American tendency to make the ovens narrower, and mention is made of the Bury and Ollander process for the recovery of ethylene, and its conversion to ethyl alcohol, although it is not described. The reviewer fully appreciates the impossibility of describing in a volume of this size, every process and development of such an industry, but feels that two such important points should have received more than a mere passing remark. The book is undoubtedly invaluable to the student, and is essentially practical, great attention having been paid to detailed description of processes and plant; also it is exceptionally well illustrated, containing in all 131 illustrations. Greater care, however, might have been taken in revising, in which case many irregularities, such as the following example, would have been avoided. On page 184 is found "A plant to work the Cobb process on the large scale dealing with Mond gas, is being erected." This passage also appears in the previous edition of 1916, and it would appear that the erection was unduly prolonged. It is no easy task to mould one's thoughts to fit the grooves made by a predecessor, and Mr. Myers would undoubtedly have done greater justice to himself if he had written a new book on the subject, in his own way, and it is to be hoped that in the near future we shall have the pleasure of reading such a book.

THOS. BIDDULPH SMITH

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Sept.* 20)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Tiles, paint, builders' wares	412/7/1/1/154
,, ..	Leather	412/7/1/1/158
Canada ..	Tarred and asphalt felts, roofing materials	*
Egypt ..	Cast iron tubing ..	315
Italy ..	Pitch	20579/F.W./M.C.2
Netherland E. Indies	Tinware, enamelware	316
Rumania ..	Bronze (tender) ..	11508/F.E./E.C./2
South Africa	Brass (tender) ..	12162/E.D./E.C./2
,,	Traction lamps (tender)	12161/E.D./C.C./2
United States	Leather	320
Uruguay ..	Fuses (tender) ..	8686/F.L/.C.C./2

* Canadian Government Trade Commissioner's Office, Portland House, 73 Basinghall Street, E.C. 2.

TARIFF CUSTOMS EXCISE

British Empire.—The current issue includes an abbreviated form of invoice and certificate for use of colonies assessing duties on "invoice price."

British North Borneo.—The duty on petrol, benzine, gasoline and similar oils and spirits has been fixed at 25 cents per gall.

Germany.—An increase has been made in the rate of the internal tax on sugar.

Japan.—Until the end of March, 1924, the import duties are suspended on many goods, including certain acids and chemicals, paper, cement plate, and sheet glass, iron and steel, and electric wire.

Mexico.—The import duty on soap has been raised to 0·15 pesos per kg.

Norway.—A statement regarding the basis of assessment for goods dutiable *ad valorem* is given in the current issue of the *Board of Trade Journal.*

COMPANY NEWS

NOBEL INDUSTRIES, LTD.

Presiding over the annual general meeting on September 21, the Chairman, Sir H. McGowan, said that the company's factories were kept well occupied during the year and there was a ready sale for most of their products. Efficiency had been improved, owing to concentration of manufacture, and prices of explosives had been reduced. The export trade showed encouraging improvement, particularly in South Africa. Factories had been erected in Chile and Czechoslovakia, and others were being erected in Hungary and Rumania. There was an improvement in the metal business of the company, the holdings in the Dunlop Rubber Co. and the General Motors Corporation had not been altered, and the prospects of the British Cellulose and Chemical Manufacturing Co were much better than they were a year ago. The future was uncertain, and it could not be foreseen when conditions would become normal. Business so far this year had been promising, and it was anticipated that results this year would not be below those of 1922.

The gross profits for the year ended December 31 last were £1,157,137, compared with £809,242 in 1921. After providing £176,999 for interest (less tax) paid and accrued to December 31, 1922, upon the 8 per cent. seven-year secured notes, the balance was £980,138; £37,236 was written off the cost of note issue, leaving a net profit of £942,901 (against £604,264). The balance brought forward was £463,349. After allowing for the preference dividend for the year it is proposed to pay a dividend of 7 per cent. on the ordinary shares (against 5 per cent.) less tax, to write off the balance of "cost of eight per cent. note issue," the notes having been repaid in May, 1923, £148,945, and to carry to reserve £50,000 (against £350,000). The carry forward is £509,018.

CALICO PRINTERS' ASSOCIATION, LTD.

After providing £597,305 for maintenance, depreciation, repairs, renewals and upkeep, and £128,000 for debenture interest, the profits for the year to June 30 last are £800,208, to which £237,371 brought forward is added, making a total of £1,037,579. It is proposed to devote this balance to payment of a dividend of 5 per cent. per annum on the preference shares for the year ended June 30, against which the directors have declared and distributed an interim dividend on March 31 for the six months ended December 31, 1922, £150,805; to payment of a 10 per cent. dividend on the ordinary shares for the year ended June 30, £201,073; to payment of a bonus on the ordinary shares for the year ended June 30, at the rate of 2½ per cent., £50,268; to reserve account, £150,000; to reserve for equalisation of dividends, £150,000; to employees' benefit fund, £100,000; leaving a balance to be carried forward of £235,432.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is slightly better, but still much below normal. Orders remain small in bulk. Prices are steady and even firmer where stocks are slight.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw.	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali	£7 12s. 6d.—£8 per ton. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 per ton. Dull.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. More inquiry for forward delivery.
Brown Sugar of Lead	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d.—1s. 2½d. per lb. Good demand. Market firmer.
Crude 60's	3s. 3d.—3s. 6d. per gall. Good demand for spot delivery.
Acid Cresylic—97/99	2s.—2s. 5½d. per gall. Fair demand.
Pale 95%	1s. 10d.—2s. 5d. per gall. Market quiet.
Dark	1s. 10d.—2s. 0½d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price.
Anthracene Oil—	
Strained	8¾d.—10d. per gall. Supply short.
Unstrained	8½d. per gall.

Benzole—	Fair enquiry.
Crude 65's	1s. 1½d. per gall.
Standard Motor	1s. 6½d. per gall. delivered buyer's works.
Pure	2s.—2s. 1d. per gall. d/d. buyer's works.
Toluole—90%	1s. 7d.—1s. 9d. per gall. Little business passing.
Pure	1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9¾d. per gall. Steady demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 3d.—1s. 6d. per gall.
Solvent 90/190	1s. 3d.—1s. 4d. per gall.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Supply short, demand increasing.
Whizzed or hot pressed	£11—£12 per ton.
Naphthalene—	
Crystals	£20 per ton.
Flaked	£20 10s. per ton.
Pitch, medium soft	125s. to 130s. per ton. Market quiet. Few sellers.
Pyridine—90/140	21s.—21s. 6d. per gall. Market very strong. Price still advancing.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 10d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 7d.—1s. 8d. per lb. Market weaker.
Acid Sulphanilic	1s. 1¼d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d.—10d. per lb.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	5s. 0d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	6d.—6½d. per lb. Prices firm with a good steady demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
d-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 6d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 6d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	5s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	3s. 3d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	4s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Business is still quiet, but prices remain steady, Continental quotations being increasingly firm.

Acid, Acetic 80% B.P.	£52 10s. per ton.
Acid, Acetyl Salicylic	3s. 1d.—3s. 2d. per lb. Good demand. Firm market.
Acid, Benzoic	2s. 3d.—2s. 6d. per lb. Firmly held. Some German makers are stated to be out of stock.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 5½d.—1s. 6d. per lb., less 5%. Supply exceeds demand.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb., according to quantity.
Acid, Salicylic	2s. 2d.—2s. 3d. per lb. Firm market. Good inquiry. Supplies not heavy.
Acid, Tannic	3s. 3d. per lb. for B.P. quality.
Acid, Tartaric	1s. 2d. per lb. less 5%. Market continues weak.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 6d. per lb. for English manufacture. Imported higher. Market very quiet.
Amidopyrin	12s. 6d. per lb. Demand still very poor.
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	17s. per lb. for quantity.
Benzonaphthol	4s. 6d.—4s. 9d. per lb. Slight advance in price.
Bismuth Salts	A steady market.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	6½d. per lb. Foreign market appears a little more stable. Not much inquiry.
Ammonium	7d. ,, ,,
Sodium	7½d. ,, ,,
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.
Chloral Hydrate	3s. 9d.—4s. per lb. Somewhat firmer. English makers are oversold.

Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.
Creosote Carbonate	8s. lb. Demand negligible.
Formaldehyde 40%	75s. per cwt. ex wharf London.
Guaiacol Carbonate	8s. 6d. per lb.
Hexamine	3s. 6d.—3s. 9d. per lb. Spot parcels have been cleared, and forward prices are higher.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s.—3s. 3d. per lb. Now asked, according to quantity and holder.
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.
Magnesium Carbonate— Light Commercial	£37 per ton net.
Magnesium Oxide—	
Light Commercial	£82 10s. per ton, less 2½%.
Heavy Commercial	£28 per ton, less 2½%.
Heavy Pure	65s.—75s. per cwt., according to quality & quantity.
Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Very much weaker. Reduced 6d. lb. all round. Quicksilver reduced to £8 15s. per bottle.
Methyl Salicylate	2s. 4d. per lb. Distinctly firmer for English or imported, in view of normal increasing demand.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid : Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9d., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 5d. per lb.
Paraldehyde	1s. 5d. per lb. Demand slow.
Phenacetin	6s. per lb. Steady.
Phenazone	7s. per lb. Firm.
Phenolphthalein	6s. 6d.—6s. 9d. per lb., according to quantity and holder.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	2s. 8d. per lb. English makes are meeting foreign competition.
Potass. Iodide	15s. 8d.—16s. 2d. per lb. Good demand.
Potass. Metabisulphite	8d. per lb.
Potass. Permanganate	10d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Salol	3s. per lb. Limited demand.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 6d. per lb. Improved demand would lead to higher prices as present stocks cannot be replaced at current figures.
Sod. Citrate, B.P.C. 1923	2s. 3d. per lb.
Sod. Hyposulphite— Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	Powder 2s. 6d.—2s. 7d. per lb., and Crystal at 2s. 8d. per lb. Distinctly firmer. Demand more active, and supplies not excessive.
Sod. Sulphite, anhydrous	£25—£26 10s. per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	14s. per lb.
Tartar Emetic	1s. 2d.—1s. 4d. per lb.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Bulgarian	34s. per oz.
Anatolian	24s. per oz.
Palma Rosa Oil	23s. 6d. per lb.
Peppermint Oil—	
Wayne County	15s. 9d. ,, ,, Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	7s. 6d. per lb.

TRADE NOTES

Trinidad and Tobago, 1921

The staple agricultural products of the colony are cacao, coconut and sugar. Heavy rain reduced the sugar crop by 3500 tons to 54,933 t., and the export comprised 46,149 t. of sugar and 6792 galls. of molasses. Much attention is being paid to the elimination of disease in the sugar-cane plantations. The exports were over 20,000,000 nuts and 4,196,703 lbs. of copra, valued at £108,725 and £61,989 respectively. Rubber is grown on a small area, but tapping has been stopped for the present owing to the low price. The lime industry is considerably hampered by general prevalence of disease. At the end of 1921 twenty companies were producing petroleum from an area of 100,000 acres, the total number of wells drilled in the colony being 607. Petroleum production amounted to 82,395,595 imperial gallons, an increase of 9,489,648 galls. over the previous year; in addition 119,729 t. of asphalt and 227,244 t. of road-building material were produced during the year. Imports were valued at £6,903,694, of which 25·37 per cent. came from the United Kingdom, 20·99 per cent. from other British Possessions, and 36·11 per cent. from the United States. Of exports valued at £683,988, the United Kingdom took 40·54 per cent., Canada and other British Possessions 12·99 per cent., and the United States 28·53 per cent.—(*Col. Rep.-Ann.*, No. 1135, 1922.)

French Company News

It is reported that the Société Pathé Cinéma intends to establish a factory in England for the manufacture of sensitive kinematograph films.

A new company entitled "Soie de Compiègne" has been established for the manufacture of artificial silk.

The St. Gobain glass and chemical company intends to add a department for the manufacture of superphosphate to its works at Wasquehal.

The Société Industrielle du Celluloid now controls the Société l'Agatine, which manufactures a non-inflammable plastic material from phenol and formaldehyde.

Market News

There is a certain tension in the market for resins and turpentine, as most of the factories have paid high prices for raw materials and prefer to stock their products rather than sell. On the other hand, consumers are not buying, and as a result prices are fluctuating widely. The price of turpentine has risen from 465 francs on September 11 to 505 francs on the 19th. Prices for dry products are well maintained, viz., tar, 82 francs, colophonies 86 to 87 francs. Tars are in good demand, especially from Italy and Northern Europe. It is not known what stocks of turpentine are in hand in the Landes, but it is supposed that stocks unsold at the works are fairly high, although those in warehouses are smaller.

INSTITUTION OF CHEMICAL ENGINEERS

Owing to great public demand, a limited number of copies of the paper on "Industrial Oxygen," read by Mr. T. Campbell Finlayson (Associate-Member), B.Sc., before the Institution of Chemical Engineers in June last have been published, and are issued to the public at the price of 10s. 6d. each.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES   London, October 5, 1923   No. 40

EDITORIAL

EVERY manufacturer, whether of chemicals or any other products, is interested in the efforts made by Governments to promote trade. Here such efforts may be placed in two categories, first, the participation of the Government directly in some species of manufacture as in the construction of ships or by investment in some company, instances of which will readily occur to our readers, second, some legislative action intended to foster a particular industry. The investment of money in an industrial undertaking is due either to a desire to make a profit or to a sentimental feeling of benevolence in favour of some person other than the investor. Government investment is usually of the latter variety; a business may be so lucrative or so well-organised as to appeal successfully to those who are willing to invest twenty pounds in the sure hope that these will speedily be converted into five and twenty. Such a business needs no Government aid in raising its capital. On the other hand, the sentimental investor has no right to expect profits. The making of money is a legitimate occupation, but it must be pursued with that intention and every other consideration which influences the business will be at the expense of the profits. Legislative measures for the benefit of an industry usually involve a prohibition to import or manufacture certain goods unless some penalty is paid. It is obvious that the arguments in favour of such a course, and those against it, will be very prominently brought before us in the near future. With such arguments and their relative merits we are not and shall not be concerned, but it is a matter of common interest to notice here and there the signs of greater stability or prosperity in the world. In this country our national finances have, from the point of view of currency, been rectified very speedily. Our French and Italian friends admit this but direct our attention to the fact that our deflation of currency and high taxation have caused an army of unemployed. It is all very well for the man who owes more than he can pay to deny himself every luxury, but if he knocks off his bread and meat as well, he will die of starvation before his balance is a credit one.

* * *

The French have avoided this rapid deflation or, rather, have postponed it, for they have only put off that evil day. Perhaps they will carry out this operation so slowly as to cause little temporary inconvenience, if so, it will be a long while before their national finances are sound. We have compressed our trouble into so short a time that the remedy can hardly be endured, but we are nearer than any other European country to a sound financial condition. Whether we are wise or foolish depends not on our study of the problem but on our political faith. The balancing of probabilities and weighing the advantages against the disadvantages of any course are far too difficult questions for the decision of those who will have to make the choice. Meanwhile, there is consolation to be derived from the fact that a certain measure of stability has been reached in some countries, Austria is one, for instance. If we compare the present state of the world with its state two or three years ago there are signs of progress; even Russia seems to have risen a little from the very low position she recently occupied as a trading concern. Desperate as is the condition of Germany, and extraordinary as are her currency problems, there seems to be a feeling in many quarters that she has reached a crisis in her currency and financial problems from which a recovery seems almost certain. Even if this particular crisis is successfully weathered, she will have other, but less severe ones, for her shortage of the necessary basis for a stable currency will be an important factor for a long time to come. We wish some means could be found for hastening the golden age, but catalysts for this process are yet to be discovered and we much fear that patience and determination will be the conditions most necessary for our comfort.

Nothing short of a well-known Americanism would be sufficient to describe adequately a consulting chemist's practice in which the work ranged from the examination of quinine, matches, dyes, beer, soap and condensed milk to analyses of sheep-dip, cocaine, tea, paint, cheese, radioactive materials, tobacco and alloys. Yet such a laboratory is in existence in Clement's Inn, where the Government Chemist and his staff are quietly engaged in work of great national importance, Everyone who has had experience of analytical work will feel in sympathy with Sir R. Robertson, when he writes in his report, referring to work done in connexion with the Safeguarding of Industries Act, that the analysis of many of the samples such as medicines, perfumery and proprietary articles, is of an intricate nature, especially as in some cases no information is available as to the composition of the goods. Those who are pessimistic about the state of chemical education in this country should note that in all the samples examined under the Fertilisers and Feeding Stuffs Act, there was substantial agreement between the results obtained in the Laboratory and those of the agricultural analysts who had first examined the samples. And in another part of the report it is stated that similarly efficient work is being performed by the chemical stations established in the chief seaports. Curiously enough, search in various books of reference failed to reveal any information about the Laboratory. A cynic would perhaps say that this silence explained certain peculiarities of the schedules to the Safeguarding of Industries Act.

* * *

This week it has been our privilege to receive officially from the Chemical Society, abstracts of the papers to be read at their meeting on the 4th inst., to prepare for the distribution of advance proofs and to arrange for the publication of these and the discussions following the papers in our next issue. The Chemical Society and the Society of Chemical Industry have much in common, many of the distinguished Presidents of the senior society have also presided over the junior one. The Chemical Society has given to the Society of Chemical Industry the privilege of using its library and its lecture hall; there has always been the bond that each Society existed, not for the gratification or profit of any individuals, but for the advancement of science. Each Society has contributed a number of zealous workers to the Federal Council whose influence is probably greater than its publicly announced achievements. To the support of the Chemical Society this journal already owes much and, with that gratitude which consists of a sense of favours to come, we welcome their help in enabling us to publish so rapidly and with such authority, an account of the communications submitted to the oldest chemical society in the world.

ENZYMES

At a meeting of Section B (Chemistry) of the British Association at Liverpool University on Monday, September 17, a discussion upon Enzymes was opened by Dr. E. F. Armstrong, F.R.S.

Dr. Armstrong said that the study of enzyme action now resolved itself very largely into the study of surface effects. Indeed, he ventured to predict that the subject of surface effects would be one of the most important matters discussed by chemists during the next few years. He was gratified to find that the President of the Section had devoted so much attention to it in his Presidential Address. Sir Ernest Rutherford and his colleagues were dealing with what might be termed the innermost centre of matter—the atom. Surface action was what was taking place right at the outside of the aggregates of molecules which make up matter as we know it.

Enzymes are catalysts found in plants and animals which apparently enable the plant and animal very easily, at comparatively low temperatures, to bring about reactions which in the test tube require high temperatures and strong chemical agents. They belonged to the class of substance known as colloids, and their action was largely a question of surface action. The reactions brought about by enzymes were, in the main, hydrolytic—*i.e.*, they concerned active hydrolysis when water was split into HO—H, or alternatively, they involved oxidation and reduction, which were only two phases of the same thing; in that case water was split into H_2—O, so that the study of enzyme action was virtually a study of changes in water.

As to the preparation of an enzyme, animal or vegetable tissues—yeast was a good example—were taken and the cell wall ruptured in some way; in the case of yeast, by drying it. Then an aqueous extract was made of the enzyme and the filtrate—an opalescent liquid—possessed properties which were attributed to the presence of an enzyme. Yeast extract, for example, would hydrolise cane sugar. It used to be considered that the enzyme was truly in solution, and it was spoken of as a soluble enzyme, but he believed the view to-day was that we are dealing not with a true solution, but with a colloid gel. If we were dealing with a material of that kind, then we were justified in imagining that the action is taking place at the surface of the molecule—the molecule being a big one—and going a little farther in the study of the enzyme we had discovered numerous cases in which all the action required could be obtained without dissolving the enzyme, all of which action took place at the surface of insoluble material, the hydrolysed substance acted upon being in true solution. Therefore, it was quite clear that enzyme action was a surface action.

The next stage in the investigation of the enzymes over a period of years was the rate of their activity. Physical chemistry, in its application to natural problems, had the advantage of bringing in exact science in the sense that it enabled us to make measurements. It was, perhaps, however, necessary to add a word of warning with regard to the use of these methods of measuring the rate of action, viz., that it was necessary to be quite sure that we were really measuring what we think we are. As a matter of fact, very nearly half the experiments on record with regard to enzyme action were not measuring the rate of activity of the enzyme at all; they were measuring something quite different, in many cases the rate of accumulation of impurities in the solution, the rate of destruction of the enzyme and not the rate of action of the enzyme.

As a result of work done in all parts of the world during the last twenty-five years, many people were agreed that, as with other active catalysts, if the enzyme were really active and the solution such that plenty of material was brought to the surface all the time, then the rate of action was such that equal quantities of material were attacked—hydrolysis or oxidation, as the case may be—in successive equal intervals of time. If this were accepted, then all idea of mysticism was removed from the action of enzymes, because it was incredible to think that such simple actions as digestion, which went on in a body, or the recovery of muscular tissue after work, should be governed by very complex mathematical laws.

It would, perhaps, be worth while adding a word of caution as the result of experience, and to say that for enzyme work considerable training was necessary. Enzymes, as active catalysts, by virtue of their surface, were naturally rather sensitive to outside influences. Traces of alkali in particular, and acids to a less extent, affected their activity enormously. It was therefore necessary that all work should be carried out in hard glass beakers and flasks and that all solutions should be kept in hard glass bottles, and also that hard glass pipettes and burettes should be used, and it was neglect of such precautions which had led to the anomalous and complicated results to be found in the literature.

If enzymes were regarded as colloids, then we could bring to our assistance all that was known about other colloids and catalysts, particularly the fact that as a colloid aggregate was active in virtue of its surface, every possible means must be taken to keep that surface clean. It was quite obvious that if the surfaces were allowed to be attacked by chemical acids and alcohols, the surface would be harmed in some way. A great deal of evidence to this effect was brought forward by the Colloid Committee of the Section.

Referring again to the yeast extract, the best way to make a strong enzyme from yeast was to take ordinary brewer's yeast and put some in a bottle with a little toluene on the top, and place this in an incubator at a temperature of 36° for a week or more until the whole of the yeast melted down to a dark brown liquor which, after filtering from impurities, was a thick, opalescent, though very dark solution. This could be precipitated by the cautious addition of alcohol, to a brownish whitish slime, a sort of colloidal substance which, after washing by alcohol, could quickly be re-dissolved in water, and gave a much cleaner solution, slightly active. If that process was repeated with care a dozen or more times there would be less and less material and the activity increased. They would then begin to test with ordinary organic groups and would find, as the purification was carried farther and farther, that the reaction with sugars grew fainter; the reaction with amino-acids and protein bodies, and, in fact, nearly all the reactions would grow fainter. Generally, in any one series of experiments, most of the reactions disappear except one, and the investigator might think he had made a discovery as to the destruction of enzymes and might publish a paper upon it. But if the investigator had more experience he would do it all over again, and would find that the reaction, which did not disappear at first, disappeared the second time and that one of the others persisted; and after this had been done several times, the investigator would no doubt decide not to publish a paper.

From his point of view, he was quite clear that we could never hope to purify the enzyme, because there was no such thing as an enzyme in the sense that there was a molecule, say of cellulose; considering the molecule of cellulose we were pretty clear—at any rate, Prof. Irvine was—as to what it should be like. So far as the enzyme was concerned he thought it was highly improbable that there was such a thing at all; we have a big colloid surface, and one part of it contains a certain grouping which, with the proper physical conditions, is built up as a catalyst and possesses the activity with which we associate the name enzyme. Therefore, he hoped that his physical-chemical colleagues would devote much attention to the study of the peculiar particular surface condition which brings about this high state of activity. What chemists wanted was to get some evidence as to the particular groups for each specific enzyme action. Actually we had no means at our disposal at present to allow of any proof being put forward. The hypothesis was there and some day he hoped we should be able to test it. We were certain that there was a definite relationship between the activity of the enzyme and the substance on which it acts. Each particular enzyme restricts its activity to nearly one subject. Fischer had studied the action of these enzymes and showed that there is the closest relation between the structure of glucose and the activity of the enzyme. Moreover, Fischer suggested the analogy of a lock and key to show how to fit an enzyme on to sugar and that idea had prevailed in the minds of most of those who had studied the subject ever since, but it was rather an unfortunate analogy from our present day point of view because it did not correlate itself with the idea of surface at all. He himself had been very much helped by Langmuir's conception of the state of affairs in the case of a drop of fatty acid on a water surface. Langmuir imagined that when there is fatty acid on water the carboxyl group is on the surface of the water and that the rest of the molecule rears itself proudly in the air with a CH_3 group sticking out at the top. Hardy had stated that when two pieces of glass with an organic liquid between them were rubbed together, there was a great tendency for the chemical molecules to arrange themselves in a definite orientation, and all our space lattice theory of the structure of metals fits in with this new conception. Now we are able to take the sugar molecule and arrange it at the surface of the colloid, not with the lock and key idea, but in some such way that it completes an electrochemical circuit while the action takes place.

After referring to the paper read by Professor G. Hopkins at the recent meeting at Cambridge, he turned to the nature of the first phase of the reaction between the substance attacked and the enzyme. There were two rival theories at the moment. The first is that some kind of complex is formed between the enzyme and the substance which it attacks, and that the forces which bring about the formation of that complex are chemical forces. This is suggested as some loose form of complex, but nevertheless it is formed by chemical forces. The physicists, however, have the idea that this active layer of colloid is able to adsorb or absorb the substances, the forces holding it being physical. The work of Hardy and others has shown that this adsorbed layer is generally a molecule thick, or not very much more. He thought there was very little doubt that both the physicists and the chemists meant the same thing although they were expressing it differently. It was not possible at the moment to offer proof of the formation of these complexes in the case of enzymes, but it was possible to offer it in the study of other catalysts, particularly the nickel catalyst. If they had a fatty acid; $CH_3— \cdot \cdot — CH : CH — \cdot \cdot \cdot —CO_2H$, the complete substance containing 18 or 20 or even more carbon atoms, and also a nickel catalyst, the theory is that a loose complex is formed by the two substances, and the point of attachment of the complex is the CH : CH part of the above expression. Chemists knew that if in their test tubes that compound was formed and broken down again, it will break down not only to the original substance but in every other possible way. The substance selected could break down in more ways than one. There was the syn form and the anti form, and if this theory is correct we could expect amongst the products of reaction both the syn and the anti form. For instance, in the case of oleic acid, if the reaction with hydrogen was stopped when it had gone, perhaps, half way, in addition to stearic acid there would be obtained an isomer of oleic acid. In fact, a considerable quantity of elaïdic acid was obtained. That seemed to him to afford convincing proof that such a complex is formed. If to that proof were added the extraordinary effect of the structure of the sugar, then he thought the evidence was absolutely in favour of the formation of a definite chemical complex between the enzyme and the substance which it acts upon.

It seemed as if the formation of the complex is necessary for the formation of an electrochemical circuit where the energy was provided by radiations or by the ultra-violet light with which Prof. Baly was working. If we once solve this problem, then we have a clear idea of the manner in which changes are brought about in the living organism. The plant or the animal actually controls what happens inside it because its active agents are such that they only come into operation when an organic compound of a particularly complex structure is present. We had got a glimmering, which in a few years might become a certainty, of the actual groups in the enzyme which possess the power of initiating these far reaching changes.

Prof. E. C. C. **Baly** believed, on the energy quantum theory, it was possible to found an explanation of the supply of energy by means of a catalyst to the substance which has been catalysed, which he would call a catalyte for want of a better word. There were two ways by means of which the addition compound between two molecules could be stabilised. If they had two molecules, which he would call A and B, the complexity of which did not matter, to form a complex between the two there were two possibilities. The first was one with which we are familiar—viz., that the energy content of the resulting complex is less than that of the two components. In other words, both of them lose energy, and a stable complex was formed which could not be resolved back again into its two free components A and B until the amount of energy lost in the formation of the complex had been restored. There were many complexes of that type, and a typical example was aniline hydrochloride. But there was another possibility—viz., that the complex is stabilised by a definite transference of energy from one component to the other, and then such a complex cannot be resolved back into its components until or unless the energy goes back again from one component to the other. In the case of the two molecules A and B, the transference of energy from one to the other must be considered as a purely isothermal reaction, and the amount of energy transferred on the energy quantum theory must be one, two or three energy quanta per molecule, and, if that were so, it must be capable of experimental proof. It was possible to determine, by physical methods, energy changes of that type—*i.e.*, where a molecule loses one quantum of energy or gains it. He had made a series of investigations in which a particular substance A had been examined spectroscopically, together with B and finally the complex A B had been examined, and he felt he could say that there was a certain amount of definite proof that a change had actually taken place between the two; A had lost energy and B had gained it, the whole change being accompanied by no transference of energy to or from the surroundings.

Dr. **George Tate** asked whether the reaction brought about by an enzyme was reversible.

Professor **Robinson** said an idea which had been running through his mind for some time, which he had never published for lack of experimental evidence, was in regard to the nature of polymerisation in all classes of organic compounds. A large class of polymerides was derived from reactive groups at both ends of the molecule which could combine with one another, and there were two possible theories as to such polymerides, although only one had been suggested hitherto. The theory that had been suggested was that these polymerides were principally chemical polymerides, and consisted of enormously large molecules. Another possible theory which had occurred to him, however, was that the unit of the polymeride was a fairly large ring, and that these rings were interlocked and unable to separate one from the other. The evidence on which that was based was very slender, but there was a certain amount. Dr. Armstrong had mentioned cellulose. Principal Irvine's idea, however, he did not think was sufficient to explain the character of cellulose. In fact, the unit of cellulose must be regarded as a polymeride, and under the possible idea of polymerisation which he had just put forward there would be a large number of interlocked rings, each of which would be the Irvine cellulose unit. The question, of course, arose as to what experimental evidence there was, and he thought it was to be found simply in the complete absence of the end member of the chain in the cellulose unit.

Prof. H. S. **Raper**, speaking as a physiologist, said we needed an explanation of where the energy came from in an enzymic action. We had not a satisfactory explanation of how the catalyst was regenerated—*i.e.*, how it replaced the energy it had lost.

Prof. H. E. **Fierz** said that ultra-violet rays had no effect at all in the chlorination of toluene. He had not been able to come to a conclusion with regard to this, but it would be interesting to know whether Prof. Baly had ever absorbed completely the heat waves. It was quite possible that if the heat waves were taken away and there was absolutely cold ultra-violet light, there might be no reaction.

Prof. **Baly**, in reply, said that one could realise how it was that these reactions of enzymes could be so easily carried out by means of an enzyme, and yet were exceedingly difficult to carry out by the action of heat. With regard to the chlorination of toluene mentioned by Prof. Fierz, he would assume that for the particular reaction only one quantum is necessary—*i.e.*, energy has to be absorbed so that the total amount is of the order of 3000 calories per gramme molecule, which corresponded to the absorption band in the infra red, about $3{\cdot}5\mu$. It followed that it should be possible to carry out reactions by means of infra-red light which was absorbed at the characteristic intensity of the toluene or chlorine in the infra red. Chlorine had no absorption band, as a matter of fact, but toluene had, and, assuming that one quantum per molecule was just sufficient to carry out the reaction, that explained why Prof. Fierz had found no reaction with the ultra-violet light, and that point was an extraordinary contribution to the radiation theory of chemical reaction, which he was sure Prof. Lewis would be very much interested in. If energy was absorbed at the ultra-violet absorption band of toluene, instead of just one quantum of energy being absorbed, he believed that twenty-five times that quantum would be absorbed, and the result of the absorption of that larger amount of energy was quite different from the changes produced with one quantum. If twenty-five times the quantum were used, the toluene would be in such a condition that it would not react with chlorine. There was a definite condition for each particular reaction, and for each specific reaction there must be the corresponding condition.

Dr. **Armstrong**, replying to the discussion, said it had been asked whether enzymes synthesised the same material as they hydrolysed. His answer to that was that he wished he knew. Sir Wm. Bayliss said they did, and the French people said they did, but personally he had never been able to get any evidence in the affirmative, although he had tried over and over again for twenty years. In the test tube we were unable to realise the conditions which took place in Nature. Probably in nature the enzyme could act reversibly, but in the test tube there was no favouritism. Every possible reaction took place, and there would be synthesis of both forms; but the balance would lie in favour of the one which was ordinarily not destroyed, and we should tend to get not the natural, but the isomeric form synthesised.

SOME BIOCHEMICAL EFFECTS OF POLARISED LIGHT*

By ELISABETH SIDNEY SEMMENS
(Amy, Lady Tate Research Scholar)

Starch is formed in the leaves of a plant to about 6 p.m., and after that time sugar becomes more evident. As the vertical light from the evening sky is polarised, it seemed possible that the above change, like many other facts in plant and animal life, may be due to a specific action of polarised light.

About eighteen months ago some experiments were undertaken to determine whether plane-polarised light has any effect on the various stages of plant growth. Plane-polarised light was found to cause a definite acceleration of germination and of flower production, but apparently not to influence the vegetative growth of the stem and leaves. Since these results might be explained as being due to an acceleration of the breaking-down of the reserve stores of starch, etc., an explanation which would also satisfy the appearance of sugar in the growing leaf in the evening, the following observations were made :—

Equal amounts of ground and sifted mustard seed were placed in three glass dishes and to each was added the same quantity of water. One of these dishes was exposed to plane-polarised light, one was exposed to ordinary light, and the third was kept in the dark. After definite periods the contents of the dishes were boiled and filtered, and the amount of sugar formed was estimated by Fehling's solution or by potassium permanganate. The results distinctly indicated that an increased hydrolysis is caused by polarised light.

The difficulty of eliminating the non-coagulable proteid and other reasons led the author to investigate the hydrolysis of starch grains under conditions which were under greater control. Washed and centrifuged starch grains were shaken up with diastase and water, and a few drops of the suspension were placed on each of three microscope slides. These three slides were then mounted on three microscopes, and in one case the slide was illuminated by a beam of plane-polarised light, in the second by a beam of ordinary light, while the third was completely covered. The three instruments were placed close together so as to secure equality of temperature, and this was checked by means of a delicate thermocouple. The progress of hydrolysis was observed through the microscopes, and after intervals of from one to four hours, depending on the intensity of the light and the strength of the diastase, the starch grains broke up on the slide exposed to polarised light, there being slight erosion in ordinary light and practically no effect on the control in the dark. Altogether 23 separate experiments were carried out, using daylight from a north window or artificial light from an Osram lamp, the polarising apparatus being either a Nicol prism or reflecting surfaces of ferrotype, covered with glass, set at the polarising angle. In 17 experiments evidence was obtained of the accelerating influence of the polarised light on the breaking-up of the starch grains, and it should be mentioned that the difference between the effects of polarised and ordinary light decreased as the strength of the diastase was increased.

With shorter exposures the presence of dextrin in the hydrolysed products was proved by iodine, and after longer exposures the formation of reducing sugars was detected by warming the slides after the addition of a few drops of Fehling's solution.

The starch was obtained from potato, maize and wheat. Diastase was added to the first two, but as the wheat was freshly grown, the wheat starch was hydrolysed by its own diastase. On the slides carrying the wheat-starch preparation some proteid was present, and this was also hydrolysed under the influence of polarised light. This phenomenon is at present under investigation.

Some attempts were made to compare the relative rates of breaking-up of starch grains under the following conditions : (*a*) In light polarised by a Nicol prism ; (*b*) In light polarised less strongly by reflection ; (*c*) In ordinary light ; (*d*) In darkness ; and it was found that the rate was in decreasing order *a*, *b*, *c*, *d*, the hydrolysis being much more rapid with the strongly polarised light given by the Nicol.

It was also found possible, provided that the intensity of the light was sufficiently great, to hydrolyse starch grains in water without the use of any diastase, and here again the maximum effect was obtained with polarised light. This result is of some interest in view of the fact that even when diastase is present, chemical changes sometimes appear to commence within the grain under polarised light, before the outer membrane breaks. After a short exposure grains, apparently intact, are coloured brown by iodine and occasionally sugar crystals are seen to form as the grains break down.

Investigations of the relative rate of hydrolysis of boiled starch in polarised light and ordinary light are now in progress. Results of considerable promise have already been obtained. Although no accurate experiments have as yet been carried out on the region of the spectrum which is most effective in causing the hydrolysis, it may be recorded that the reaction is more rapid with a red glass screen interposed than with a blue glass screen.

It would seem from the above results that the evidence is decidedly in favour of the acceleration of the hydrolysis of starch by polarised light as compared with ordinary light of the same intensity.

The University of Liverpool

MEMBRANE POTENTIALS CONSIDERED AS DIFFUSION POTENTIALS*

By **E. B. R. PRIDEAUX**, D.Sc., and
W. E. CROOKS, B.Sc.

The potential differences set up at most ordinary membranes, through which a slow diffusion of electrolytes can take place, are not of the same type as those formulated and to some extent realised experimentally by Haber, Loeb, Beutner, Baur and others. The latter refer to systems which are in equilibrium on account of the complete impermeability to one or the other ion. On the other hand, there is no equilibrium in the case of the ordinary parchment, agar or gelatin membrane, swelled with aqueous liquids and not wholly impermeable to any ion. Such a membrane would appear to present a closer analogy with most living tissues.

It seems more natural to ascribe such potentials, as in the older theories of Ostwald, Höber and others to a selective ion permeability; they are non-equilibrium potentials analogous to diffusion potentials. They are, as shown by the work of Cumming and others, higher than the diffusion potentials which arise between the same two solutions. If these consist of the sodium or potassium salts of organic acids, the potentials may be of a magnitude comparable with those found in living organisms.

In the earlier work by one of the authors, it was shown that sodium benzoate solutions, with a parchment membrane, gave steady and reproducible potentials, which were simply related to the log ionic-concentration ratios of the solutions by the diffusion potential formula:

$$E_a = 0{\cdot}058\ (1-2n_A)\log\frac{a_1C_1}{a_2C_2}\ \text{volts at } 25°.$$

This formula, however, contained a value for the transport number of the anion "n_A," which was smaller than that found at freely diffusing concentration gradients, *i.e.*, the mobility of the anion was diminished relatively to that of the kation. The investigation has now been extended to potassium benzoate and salicylate. One of the objects has been to ascertain whether the benzoic ion has a definite (diminished) mobility in the parchment, which is the same in potassium as in sodium salts. Measurements of conductivities, viscosities, diffusion and membrane potentials have been made in these solutions at 25° C.

Special apparatus was designed in order to obtain a flowing junction in the case of diffusion potentials and to run the two solutions past each side of the membrane at varying speeds.

The results were treated by the method of least squares in order to obtain the average values of n_A. The total concentrations C were used instead of the ionic concentrations corrected for viscosity (for reasons mentioned in the full paper). The values of the transport number of the anion in respect of the sodium and potassium salts, respectively, were found to agree with the assumption that, given an unaltered mobility of the kations, the mobility of the benzoic anion is diminished in a nearly constant ratio, 0·725 and 0·745. That of the salicylic anion is diminished in a different ratio, i.e., 0·66. The treatment of these potentials, as modified diffusion potentials, is so far justified.

The fact that alkali chlorides, etc. diffuse quite readily through this material supports the idea that the increase in the diffusion potential is due to the retardation of the organic anion. It also shows that the diffusion potentials of such salts, even when modified by a simple parchment-like membrane, are insufficient to account for the potentials observed in living organisms. But it has been supposed by Loeb that double decomposition occurs between inorganic salts and the material of plant membranes. This might produce a concentration gradient of alkali salts of organic acids in the membrane similar to that which is supposed to be formed by the alkali benzoates in the parchment.

---

* Paper read before the joint meetings of sections (B) Chemistry and I (Physiology) at the meeting of the British Association in Liverpool on September 14.

SALT, BROMINE AND CALCIUM CHLORIDE IN THE UNITED STATES IN 1921–22

Production of salt in the United States in 1922 increased by 36 per cent. in quantity and 12 per cent. in value, to 6,792,849 short tons valued at $27,464,838, compared with 4,981,154 t. valued at $24,557,966 in 1921. In 1922 the number of operating plants was 104, a gain of 14. Sales of rock salt in 1921 and 1922 were 1,472,576 short tons ($6,693,923) and 1,947,124 t. ($7,489,644) respectively; of evaporated salt 1,931,243 t. ($16,846,963) and 2,276,683 t. ($18,472,759); pressed salt blocks 117,739 t. in 1921 ($1,275,483), and 172,682 ($1,554,429) in 1922. Imports in 1921 and 1922 amounted to 93,095 t. and 111,710 t. respectively, compared with exports during the same years totalling 109,563 t. and 134,989 t. respectively.

The output of bromine was 711,953 lb. in 1921 and 1,005,174 lb. in 1922, an increase of 41 per cent. in quantity but a decrease of 13 per cent. in value compared with the previous year. The wholesale price of bulk bromine in 1922 was 20 to 21 cents per lb. from February until about the middle of March, then increased to 27 to 28 cents until the end of the year. Bromine had not been imported into the United States for several years prior to 1921, when imports of 300 lb., valued at $84, were reported. In 1922 imports were 1094 lb., valued at $339.

The output of calcium chloride was 23,672 t. ($510,723) in 1921 and 33,067 t. ($571,326) in 1922.

THE CHEMIST AND INDUSTRY

By H. H. GRAY, B.Sc.

It is the firm belief of the writer that the British peoples have it in their power to be second to none in the world's chemical industry. Further, he is one of the many who ardently wish the British to (legitimately) lead the way ; but, and it is a considerable but, it is not quite clear that this desirable state of affairs will come about as rapidly as it might, and in the following mixture of criticism and grumbles he would like to make it quite clear, from the outset, that any note of criticism is struck, not from a querulous carping attitude of mind, but solely with the idea of bringing into the fresh air of discussion anything which seems likely to stand in the way of victory

Thoughtful observers must have been disturbed by the dramatic departures of Messrs. Levinstein and Green from the important national organisation to which they but recently belonged. Both give the same discouraging reason, namely, that the technical policy of a technical business is not given the prominence which successful working demands. Now, whatever the merits of the two cases may be, and the writer is ignorant of these merits except for information to be gleaned from published statements, one cannot dismiss *two* such cases, *two* such severances ; one cannot dismiss these cases as the hasty actions of disgruntled chemists.

Granted that chemists are queer people (quite as queer as anybody else), it would still be an eccentric judgment which lumped Dr. Levinstein with Prof. Green as a hot-tempered, nay, impulsive, resignationist.

Even if one did, for the sake of argument, grant this point, could one apply the same description to Prof. R. Robinson, who, instead of working with a single eye to our dyeing supremacy (not dying, one hopes), is working, no doubt still harder, in the academic groves of Manchester ?

These cases are, to my mind, but further instances of the general neglect of industrialists to realise that the prime essential raw material of the chemical industry is the chemist. It is possible to run a chemical works without a chemist ; nay, it must be so, since it is done ; but it is not possible, either here or in Utopia, to compete with the Continental or American chemical industry without the services of the best obtainable chemists. Yet I maintain, without fear of successful contradiction, that practically any raw material ranks in the minds of many business and commercial men more highly than does the chemist. The whims, eccentricities, departures from the normal, properties, call them what you will, of any raw material are studied, neutralised or developed with meticulous care, but where is the disposition to make allowances for, to nurture and to foster that delicate and easily dwarfed product of nature, a brilliant technical chemist who, though brilliant, cannot quite extort his own conditions ? And there are many such.

Why is it ? Whose fault is it ? Naturally there are faults on both sides. For instance, the writer is quite clear in his own mind that the ordinary commercial man, who has so much power to-day, fails to realise the necessity for thought as well as for action. Yet it can be demonstrated that all action worthy of consideration is preceded by thought processes. It can also be demonstrated that action not preceded by efficient thinking is rather uneconomical. But when will it be realised by any but the best employers that it is neither possible nor desirable invariably to combine in the one man a reflective, fruitful turn of mind with "pep" or "push and go" ?

It is still vividly within the recollection of the writer that he attended at Burlington House a meeting addressed by Prof. Donnan (one of our prophets) on the subject of the "Chemical Engineer or the Engineering Chemist." It was an absorbing subject and an inspiring address, but the discussion, alas ! was lamentable in its flat cautiousness and its uninspiring platitudes. Only two points raised in the discussion (apart from a jingoistic reference to America) stuck in the memory of the writer. One was that an employer of labour preferred to have to deal with one man instead of two in cases of trouble, since he found that the chemist and the engineer between them shuffled out of responsibility. That is, of course, a sound argument for a chemical engineer, or else for making the engineer entirely responsible for running the works with the chemist counted out as an executive. Such an argument was comprehensible and no doubt justified by experience. But another speaker, old enough to know better, actually rose, and, with a seraphic smile, intimated that in his opinion no raw graduate of a University or College was worth more than 30s. a week in his first post for a considerable time. Now, whether the old gentleman was a graduate himself is not known to me. He might, for all I know, be one of those complacent individuals who, having privately absorbed, from printed sources, large stores of knowledge, describe themselves with unction as self-made men, forgetting in their glory that nearly all the books they read and the work they absorb can be traced to the Universities they so despise, mouthing the empty phrase "the World is my University," and the like. Is it not curious how affluent age recommends low living and high thinking for turbulent youth ? And what an unbusinesslike statement ! Contrast this myopic mental attitude with the well-known practice of firms who intend to extend when they put down the hard cash for an option on a block of land or property to be held in reserve for future extension, or intended to block a rival concern. Such a mind as that of the old gentleman can clearly grasp the value of a potential warehouse or future site, but refuses to speculate on its knowledge of human nature far enough to risk more than one bottle of champagne per week in securing the future services of that priceless thing, a trained mind. Of course, it was ineptitude exalted to a fetish that produced this gem of speech, but I am afraid many people are similarly afflicted, and value an option on a shed more highly than the services of a brain.

No wonder that Lord Haldane finds it advisable to point out repeatedly that wealth is less the creation of capital or labour than of mind. After all, only mind can transform the pence of coal tar into the sovereigns of fine chemicals. Capital can draw the dividends and labour can plume itself on its indispensability, but it is mind which performs the miracle.

Briefly, I believe that employers of labour have, in the past, lacked faith, imagination and insight in their treatment of chemists.

Now, what about the chemist ? Has he no contribution to the tale of blame, no room for improvement ? Well, it would be remarkable if that were so, and the writer believes that the time is overdue for a radical change in the training of chemists. That a good many other people think so, and have thought so for a long time, is evidenced by the founding of various departments of applied chemistry, chemical engineering, engineering chemistry, etc. But this is only dealing with the superstructure ; it is the foundations of our chemical training which have been weak in the past. However, that is a highly specialised and debatable subject better omitted here.

The writer has no wish to take sides very definitely on the question of the chemical engineer versus the rest. He does not consider that the chemical engineer will succeed in monopolising the sunny spots of the earth, nor that anybody who is not a chemical engineer will die of starvation. He is quite aware that there are volumes to be spoken on both sides of this question, which was pushed to the front by a sudden and unexpected demand being made on our national supply of chemists. Still, he does know from experience that the self-conferred title of chemical engineer has covered a multitude of sins and caused the commission of many more, and he is inclined to agree with a famous teacher of chemistry, who is reported to have said that for twenty-eight years or more he had tried unsuccessfully to teach chemistry to engineers, whereas on the other hand, chemists had acquired quite a useful knowledge of engineering. Since this statement is the fruit of experience, there must be something in it, and the writer believes that there is a fundamental difference between an engineer and a chemist, and that a really good man might fail at either subject, provided he was fitted for one and put to the other.

After all, in spite of conferences, laws, threats, systems, etc., there will always be conformists and non-conformists in the religious sphere, because the two attitudes of mind correspond with fundamentally differing mental types, and the difference between a chemist and an engineer is often quite as clearly marked.

There is no doubt that we shall get results of tremendous interest and value when the workings of the new Ramsay Memorial Chair of Chemical Engineering at University College come to be published. The relative rates of absorption of the engineer and of the chemist should provide one or two interesting diagrams when total useable knowledge comes to be plotted against time.

One really splendid way to use the new department would be for employers to extend to their technical staffs the advantages which undoubtedly accrue from adult education. I believe that results of extreme value to the firms, the individual, the industry, the nation and the Universities, would follow if employers would send selected members of their staff to some such place as this new department for a refresher course. I have no doubt at all that men so refreshed would go back to industry revitalised, full of new ideas, once more young in spirit and full of a new hope. There is hardly an active mind in industry to-day but would admit, if asked, that he often sighs for a chance to fill in gaps and strike out new paths. For the true and useful chemist is not a hewer of wood and a drawer of water by instinct ; he has an evergrowing and tremendously live subject to keep him fresh and vital if only conditions are right.

Some people profess to believe that in one and the same person an engineer and a chemist can be found or produced. Such a product they call a chemical engineer. Now, although I never really believed in my heart that the authorities of University College had such futile conceptions, I must confess to a sigh of relief when I read that the new professor was to be a chemist, and I was still further impressed when it was announced (recently) that it was the intention to appoint a second member of the staff with engineering qualifications. Here now is the ideal solution of this very thorny problem, namely, that the directing intelligence of chemical concerns should be of a chemical nature, and that the executive authority (the process of doing) should be vested in the engineer. Obviously, there is no pretension here that one and the same (young) man can be a capable research chemist and an experienced engineer. And we must all fervently hope that the future products of this department will never pretend to be at one and the same time good mechanical engineers and learned chemists.

However, this is pre-eminently a case of *solvitur ambulando*, and the writer has little doubt that the genuine chemical engineer will successfully oust that mixture of impudence and bounce which, during the war, seemed to spring out of the earth in a night, the self-styled chemical engineer. The rate of increase in "chemical engineers" during the war puzzled the writer to such an extent that he could only account for it by some new method of procreation akin to that of the aphis, where the only person concerned was the individual himself.

However, let there be no misunderstanding of the writer's point of view. Chemical engineers of the *right sort* will be invaluable in industry, but let us beware of thinking that the subject of chemical engineering is a panacea for all our ills. On the contrary, it is even likely to be dangerous, since, if it threatens the prosperity of the genuine and unadorned chemical department, a good deal of harm will be done. After all, analytical and research chemists will always be required in industry, and they may be described as "academic" by certain folk, but if they are crushed out of existence there will be a heavy reckoning to pay some day.

Hit and miss works' investigations under the supervision of the plant man and under actual working conditions, however valuable they may be, will never replace systematic research work carried out in the laboratory, and if industrialists of this country fail ultimately to appreciate and *foster* real research work, they will either go bankrupt or acquire another country's results at a very high price. Those are the alternatives.

If we could only get rid of the "non-productive" theory of the accountant, of the state of mind which refuses to believe that any man can be "working" if he is caught in a thinking posture, or that knowledge is production, what a difference there would be in our industrial intelligence departments! And on the other hand, what a poor milk-supply there will be when the "speed-merchants" limit excessive time devoted by our national cows to rumination!

Finally, let me quote the remark of Prof. E. H. Starling, in a recent number of *Nature*, where he says so truly that "in Science it is the question that matters; the solution can always be found." The writer believes that that is true of industry, even in repetition work, but most certainly in the ever-changing chemical industry, because from the point of view of the chemist there is really very little difference between real science and ideal industry. All this apprehensive and dreadful anxiety about costs, about which a chemist is alleged to know nothing, is seen to be beside the point, when it is once realised that the most scientific, the least complex, and the most beautiful plant is nearly always the cheapest to instal, and the most economical to run, and that this is precisely the type of plant that experience in research will provide.*

* These notes were written before the publication of Professor Donnan's plea for a rational education of scientists as opposed to the intensive training of disproportioned specialists.—H. H. G.

A CRITICAL EXAMINATION OF BERTHELOT'S WORK UPON ARABIC CHEMISTRY

By **E. J. HOLMYARD**

Part I

The notable interest in the work of mediæval Muhammadan chemists which has arisen in the last few years probably has its origin in a fuller appreciation of the fact that the numerous puzzling problems presented by European chemistry of the early middle ages cannot be solved until a thorough investigation has been made of the rise and development of chemistry in Islam, whence it was imported to Christendom during a long period beginning in the first half of the twelfth century.

Two of the earliest historians of chemistry to realise the importance of this study were Berthelot and Prof. Eilhard Wiedemann. Whilst the scholarly researches of the latter have been comparatively neglected in this country until recently—probably because they were generally published in somewhat obscure local German periodicals—Berthelot's monumental work in three volumes (*La Chimie au Moyen Age*, Paris, 1893) at once attracted attention, and has been used—for the most part quite uncritically—by all later writers. It seems, therefore, of fundamental importance that we should arrive at a clear knowledge of the length to which Berthelot may be safely followed, of the accuracy of his conclusions and of the relation which the ground he covered bears to the whole field.

There can be no doubt, to my mind, that Berthelot's work is deserving of the most generous praise. All those who since his time have studied Islamic chemistry owe him a great debt, acknowledged or unacknowledged, and von Lippmann's section on the subject, in his invaluable *Entstehung und Ausbreitung der Alchemie*, is based principally upon *La Chimie au Moyen Age*. That remarkable genius, Moritz Steinschneider, expresses his opinion of Berthelot's researches in the following words[1]: "Mit dem grossartigen Werke von Berthelot, *La Chimie au Moyen Age* (1893), dessen 3 Band die arabische Chemie, bez. Alchemie, behandelt und einige der ältesten arabischen Schriften mit französischer Uebersetzung von O. Houdas enthält, mögen Physiker, die sich für Geschichte ihrer Wissenschaft interessieren, den Gegenstand für erschöpft halten; ja auch diejenigen, welche die Kulturgeschichte der Araber und deren Bedeutung für die Geschichte des Mittelalters nicht unterschätzen, dürften die Resultate Berthelots als für ihren Zweck ausreichend ansehen und ohne weitere Forschungen verwerten."

Coming from such an eminent authority, this praise is high indeed, and although—however diffidently—we may protest against an Arabist expressing such a dogmatic opinion on what is primarily a matter for chemists to decide, it comes as somewhat of a shock to find that Prof. von Lippmann[2] passes extraordinarily severe strictures upon "Berthelot als Historiker." von Lippmann, of course, wrote his book during the late war, when feeling ran high, and would possibly have employed less scathing terms under normal circumstances; but the fact remains that Berthelot's reliability has been seriously impugned, and until the matter is satisfactorily cleared up no historian of chemistry can feel safe in accepting, or rejecting, Berthelot's conclusions. It is in the hope of throwing a little light upon this obscure situation that the present articles have been written. It will be convenient to arrange the discussion under three heads—(1) Berthelot's qualifications for his task; (2) his choice of material; (3) his treatment of the material chosen, and his conclusions.

---

[1] Z. D. M. G., 58, 299 (1904).

(1) BERTHELOT'S QUALIFICATIONS FOR HIS TASK

It will, I think, be generally agreed that the historian of chemistry must primarily be a chemist, for otherwise he is fatally handicapped from the start. No one can dispute Berthelot's possession of this essential qualification. Secondly, it does not appear unreasonable to insist that a man who sets out to make *original* investigation of a hitherto unexplored region in the history of a science should have an adequate knowledge of the language and literature of the men whose works he proposes to study. Berthelot, however, as is well known, had not even a bowing acquaintance with Arabic, and was therefore forced to rely upon translations. These translations were made for him by Prof. O. Houdas, an excellent Arabic scholar famed especially for his translation of Bukhari's "Traditions of the Prophet." It would seem, at first sight, as though this solution of the difficulty was comparatively satisfactory, but further consideration will show us (*a*) that, even for the actual work of translation, some knowledge of chemistry is essential, and this Houdas did not possess, and (*b*) that to translate a technical work from any language presupposes in the translator an adequate understanding of the technical terms and phrases employed, and an acquaintance with cognate works in the same and other languages. This second point is of especial importance in a subject so obscure as alchemy and in a language of so rich a vocabulary as Arabic. I believe I am correct in saying that Prof. Houdas had no special knowledge of Arabic chemical treatises, and that he undertook the work of translation only at the special request of Berthelot, backed by the *Ministère de l'Instruction Publique.* My opinion, which I have less hesitation in setting down here in that it is supported by two eminent Arabists, namely, Prof. E. G. Browne and Monsieur E. Blochet, is that properly to understand an Arabic work on chemistry requires both intensive and extensive concentration, and that even the best Arabic scholar would not produce a satisfactory translation of such a work unless he was familiar with many others of the same *genre.* I may, perhaps, quote Prof. Browne's own words, taken from his admirable book on *Arabian Medicine*[3]: "I have been greatly hampered in my reading of Arabic medical books by the difficulty of determining the exact scientific signification of many words used in the ordinary literary language in a looser and less precise sense than that which they evidently bear in the technical works in question. Nor is much help to be derived from the mediæval translations of the "Latino-Barbari," who too often simply preserve in a distorted form the Arabic term which they pretend to translate." If one of the greatest living Arabists, himself a qualified physician, feels this difficulty in dealing with medical works, at what sort of disadvantage must an Arabist of purely literary training find himself when confronted with texts dealing with alchemy, a subject far more involved than medicine? Prof. Blochet remarks[4], "le sujet est extrêmement obscur et la traduction de M. Houdas souvent insuffisante."

In spite of the difficulties with which he had thus to contend, Prof. Houdas in point of fact made translations which under the circumstances must be regarded as extremely good, and they certainly are worthy of his scholarship. At the same time they often fail, as might be expected, in those very places in which accuracy is essential, namely, the technical words and phrases. To take a case in point: one of Jābir ibn Hayyān's books is entitled *Kitāb Abī Qalamūn.* Houdas translates[5] this as "un livre à Qalamoc," by reading *ilā* instead of *abī*, which is in itself an immaterial mistake; but he obviously was not aware of the fact that *Abu Qalamūn* was commonly employed by chemists as a name for the jasper, the correct translation of the title thus being "The Book on the Jasper." Similar mistakes are numerous; thus he treats the word *ustuqus* as a proper noun[6] and leaves it untranslated, whereas anyone acquainted with Jābir's writings knows that *ustuqus* signifies "the four elements" of Aristotelian philosophy; and in the same place he misreads *ās* (myrtle) for *'uss* (base or foundation), thus rendering his translation not merely unintelligible but ridiculous.

Houdas' translation thus inevitably suffers from his lack of technical knowledge, so that, even if this were all, we should be compelled to admit that Berthelot was beginning his work upon a doubtful basis. But when we read[7]

Berthelot's statement, "*j'ai revisé avec soin cette traduction littérale*[8], de façon à tâcher de lui donner un sens intelligible, autant que le comporte ce genre de littérature," and remember that he knew no word of Arabic, we cannot deny that he is wilfully breaking one of the first canons of literary criticism and laying himself open to grave censure. It is, indeed, difficult to see what justification a man could possibly have for believing himself capable of revising a professedly literal translation from a language of which he was admittedly completely ignorant. Especially is this true in the case of a work which was the first of its kind to be translated into a modern European language, and of which the very atmosphere was strange.

There is, however, no need for us to make the uncharitable assumption of Prof. von Lippman,[9] and ascribe this lapse from sound scholarship to Berthelot's egoism and conceit. It is much more likely that he was inspired by an earnest desire to throw as much light as possible upon the subject, and succumbed to the fatal temptation of trying to *make* sense instead of adopting the more toilsome but only sure path of finding out *the* sense by a comparative study of the whole field, or of at least a much wider portion of it.

We have seen, therefore, that Berthelot's whole work on Arabic chemistry rests upon an insecure foundation, since—to use the words of Prof. Ruska—the translations of the Arabic texts upon which he relied suffer from "zahllosen Ungenauigkeiten und durch vorgefasste Meinungen bedingten, irrtümlichen Auslegungen." There are, however, some factors which tell in the opposite direction, and these must now be considered. It has long been known (*a*) that chemistry was introduced into Islam chiefly from the Greek school at Alexandria, and (*b*) that mediæval European chemistry was a direct legacy of Islam. If, therefore, a man were thoroughly cognisant of both the source and the fruit of Muhammadan chemistry he would have a very valuable qualification for dealing with the latter itself. So far as I am aware, no one has disputed Berthelot's comprehensive knowledge of European chemistry of the middle ages, and we need have no hesitation in saying that the disadvantage under which he lay from having to rely on translations was thus partially neutralised. Partially only, however; for on the one hand he could not be in a position to throw any light on those problems which had their origin in Islam and were often transported bodily and unintelligently into the Latin world, and on the other lay the pitfall of reading into the Arabic works meanings and conceptions which were, in fact, of spontaneous and later European birth. Berthelot has, indeed, not been successful in avoiding either of these dangers; on the contrary, he has often failed, in addition, to realise that numerous facts and theories which he believed to be definitely European are to be found in the writings of Muhammadan chemistry. In not a few cases the errors which he thus almost inevitably made are of capital importance.

In the other direction we have to gauge the extent of his knowledge of Greek alchemy. In 1888 he published his *Collection des Anciens Alchimistes Grecs*, in which for the first time texts of the writings of these authors were made available. Of the worth of this collection I am not in a position to judge, but it is to be noted that, as in the case of the Arabic works, the translation was not made by Berthelot himself, but by Prof. Ruelle, and that the latter's version was subjected to the same treatment by Berthelot as was undergone by that of Prof. Houdas. One therefore has the uneasy feeling that, here also, one may be on uncertain ground, and although Prof. Gaster has expressed a high opinion of the work, other scholars have not been slow to pass very unfavourable judgments upon it. I think we may, however, be fairly safe in assuming that Berthelot had a pretty good general idea of Greek alchemy, and may therefore admit that he was in a position to recognise Greek ideas and influence in Islamic chemistry, though perhaps in matters of detail he was liable to go astray.

To summarise the points made in this section before proceeding to a discussion of Berthelot's choice of material, it may be said :—

(*a*) Berthelot possessed the first essential of a historian of chemistry in that he was a chemist.

(*b*) He had, however, no knowledge of Arabic and was compelled to fall back upon translations.

(*c*) These translations are untrustworthy and inaccurate from a technical point of view—which, in this case, is the vital one.

(*d*) They are further vitiated by the fact that Berthelot subjected them to a "revision" which, from the very nature of things, was bound to be uncritical, in order "to make sense."

(*e*) He had an adequate knowledge of mediæval European chemistry, which would help him to understand much of the Arabic work but which would leave him helpless in those very points where help was most needed.

(*f*) He often ascribed to Europe knowledge which came from Islam.

---

[8] Italics mine.—E. J. H.

[9] *Op. cit.*, p. 648. "Dieser grosse Mann besass eben auch grosse Schwächen und zu ihnen zählte vor allem eine übermässige Eitelkeit; sein Leitmotiv auf allen Gebieten, die er bearbeitete, war daher der Satz, den der einstige Schüler im zweiten Teile des 'Faust' mit den Worten ausspricht: 'Die Welt, sie war nicht, eh' ich sie erschuf."

(*g*) He had a better knowledge of Greek alchemy than anyone else, and was therefore able to appreciate Greek influence on Muhammadan chemical thought. But his ideas and scholarship as expressed in the *Collection des Anciens Alchimistes Grecs* have since been severely criticised by those qualified to judge.

(*h*) Finally, one may add that Berthelot possessed an inveterate habit of sweeping away as " incomprehensible " anything which he could not himself understand.

Perhaps I may be allowed to give my own experience, for what it is worth. Starting with an implicit faith in Berthelot—naïve perhaps, but natural at the sight of his imposing volumes, which give one the impression of finality—I have been gradually led to a profound and progressive distrust, until at the present moment I feel that it is quite unsafe to accept any of his conclusions without first referring to the original sources or without strong collateral evidence. This, of course, does not imply that all are wrong ; many are accurate, many others require only slight modification, and *La Chimie au Moyen Age* contains a vast amount of material of the greatest value ; but the whole is marred by the circumstance that every fact has to be checked, every statement verified, every identification investigated and every translated phrase compared with its original. It is only natural that historians of chemistry, who have for the most part accepted Berthelot's work as authoritative, should have drawn thence both the true and the false, and that thus there have crept into the literature errors which will probably prove extremely difficult to eradicate. Even the late Prof. Campbell Brown, whose excellent *History of Chemistry* has acquired a well-deserved reputation for insight and accuracy, relied entirely upon Berthelot for his account of oriental chemistry, with the result that his pages are disfigured by gross inaccuracies, ludicrous transliterations and seriously incorrect conclusions.

(II) BERTHELOT'S CHOICE OF MATERIAL

About 300—400 different Arabic treatises on chemistry are known, and it is probable that a great many more exist in private libraries in Muhammadan countries. The *Bibliothèque Nationale* contains some 30 distinct MSS., and there are several of importance in the library at Leyden. The richest European libraries in this connexion are, however, the British Museum and the National Library at Berlin. The Royal Library at Cairo contains a large number of alchemical MSS., and I have been told that the King of the Hijaz possesses a fine collection, although I cannot vouch for the accuracy of this statement.

The works vary considerably in both age and importance. The majority range from the eighth century to the fourteenth, though the MSS. themselves are in general much more modern. It is rare to find a MS. older than the fourteenth or fifteenth century, but this is a common feature in Islamic literature and there is good reason to suppose that, in the main, the writings have been accurately transmitted. This does not imply, of course, that instances of pseudepigraphy are rare ; what is meant is that, once a work was written, it was usually carefully copied, so that, although—for example—the earliest extant MS. of an eighth century book may be of the thirteenth century, we may with some confidence assume that it has not undergone serious change in the process of transmission.[10]

The problem which Berthelot wished to solve was two-fold : in the first place he desired to find the relation which existed between the alchemy of the Greeks and that of the early Muslims, and secondly he was anxious to discover whether certain of the Latin works of the early Middle Ages were really, as they professed to be, translations from the Arabic. He also incidentally wished to find whether the Arabic works of Jābir ibn Hayyān showed any resemblance to those of the Latin Geber. It is clear, therefore, that he intended to limit himself to a study of the earliest and latest periods in history of chemistry in Islam, and this is in fact exactly what he did, neglecting entirely the intervening period of three or four centuries. This limitation must be borne in mind when we come to criticise his choice of material, and it is necessary to point out that those historians of chemistry who have assumed that Berthelot investigated the whole period and gave merely the most important and interesting works in his book, have made a grave error for which the only excuse is that Berthelot himself is liable to give one that impression.

Berthelot's immediate objective, then, was (*a*) to have recourse " aux ouvrages arabes eux-mêmes et de les comparer avec les textes latins, réputés traduits d'après des œuvres congénères "[11]; and (*b*) to have translated from the Arabic those treatises or compilations " où il est particulièrement question des alchimistes grecs, et, de l'autre parte, les ouvrages qui portent le nom de [Jābir ibn Hayyān]. "

With regard to (*a*), we find that Berthelot did not succeed in discovering, or at least did not use, any work that is known in both Arabic original and Latin translation. It is true that up to the present very few of such works have been found, but one at least he had at his disposal in the *Liber Secretorum Bubacaris* (Paris MS. 6514, pp. 101-112), of which the Arabic text occurs in the two MSS., one at Leipzig and a second at Göttingen. He gives a summary of the Latin version at pp. 306-310 of volume 1 of *La Chimie au Moyen Age*, and recognises that it is undoubtedly an Arabic work. It is, therefore, strange to find that he omits to give the Arabic text, as he had here ready to hand an excellent piece of material for aiding him to arrive at a definite conclusion on one of the questions under consideration. If the reason for this omission is that he was unaware of the existence of the Arabic MSS., he cannot be acquitted of the charge of negligence, for the Leipzig MS. is very fully described in the catalogue of the City Library published in 1838. If, on the other hand, he knew of the Arabic version (which seems improbable), but considered it unimportant, he showed a serious lack of judgment, for this work of "Bubachar" (*i.e.*, Abu Bakr Muhammad ibn Zakariyya al-Razi, or Rhazes) is, as Prof. Ruska has pointed out, of the greatest value as a compendium of the practical chemical knowledge of Islam in the tenth century.

---

[10] Needless to say, the necessity of a critical study of the internal evidence, etc., is not by any means precluded.

[11] *Chim. au M. Age*, iii. 6.

Of other Latin works which Berthelot considered to be, in all probability, translations from the Arabic, he was unable to find originals, and therefore was not in a position to arrive at trustworthy conclusions concerning them. We may therefore, I think, fairly say that as far as regards point (*a*), Berthelot left the matter in practically the same state as that in which he found it, and that the whole problem is still to be solved. It is for this reason that the appearance of Prof. Ruska's promised edition of the Leipzig and Göttingen MSS. of the above work is eagerly awaited.

To turn now to point (*b*). Berthelot gives the texts of the following works which bear unmistakable signs of Greek influence: "un livre attribué à Ostanes; un extrait du ms. 1074 (Bibl. Nat.) renfermant une série de citations des alchimistes grecs; le livre de Cratès; et le livre de El-Habîb." Of these, the last two are taken from the Leyden MS. 440, which Prof. Houdas was inclined to think "n'a pu être écrit postérieurement au VII^e siècle de l'hégire et date même plutôt du VI^e siècle," whilst the first is in the Bibl. Nat. MS. *Arabe* 2605, written partly in the year 1337 A.D. (738 of the Muhammadan era).

Of these it is sufficient here to say that the choice, though small, is quite sufficient for the purpose and on the whole satisfactory; the inclusion of the works by "Ostanes" is perhaps unfortunate, as the Ostanes question is almost as puzzling as that of Hermes himself, and at once introduces many side issues of a mystical and theosophical nature, thus further complicating a problem which is already quite difficult enough. Still, the works which Berthelot chose enabled him to prove conclusively what had before been a matter of conjecture (although there was not in reality much doubt about it), namely, that Arabic chemistry is very largely derived from neo-hellenic sources—as is, indeed, definitely stated by the Muslims themselves. Berthelot's work here, however, is of value not merely in that it proved this transmission but because it showed also the nature and extent of the ideas that were transmitted, the names that were honoured and some of the theories that were generally accepted. If the treatises of Ostanes and the others are to be taken as typical of the Greek alchemy which was the seed of chemistry in Islam, we can gain a good idea of the progress that was made by the Muslims, for as Berthelot remarks, "il y a peu de chose sans doute à tirer de [the books ascribed to Ostanes] pour la chimie positive."[12] The only criticism which need be made of Berthelot's choice in this connexion is that as Khālid ibn Yazīd is unanimously described as the first Muslim who had translations of Greek alchemical works made, and studied the subject himself with ardour, it would seem that an investigation of his writings might have afforded more definite information than do the works of the anonymous or mythical authors such as Crates and Ostanes. Much of Khālid's chemical verse is easily available, and I believe that his complete (?) *Dīwān* is preserved at Constantinople.

It is, perhaps, in his treatment of Jābir ibn Hayyān that Berthelot most signally failed. A proper appreciation of the work of a man who wrote some 500 books cannot be gained by a study of only nine, and these not the most important. I do not propose in this place to offer any comment on the vexed question of the possible identity of Jābir with Geber, but will confine myself to pointing out that some 80 works of Jābir are still extant, whole or fragmentary, and that a study of them enables one to see clearly the reasons which led later chemists to regard their author with an extraordinary reverence. The choice of Jābir's works made by Berthelot is entirely misleading and inadequate. The extent of his knowledge was amazing, and to regard him as a bombastic obscurantist, as Berthelot does, is to do him a grave injustice. I hope to show later the remarkable scientific knowledge he possessed, but meanwhile I may perhaps refer to a bibliography I have made of his extant works, now in the press,[13] where those who are interested may gain some idea of the negligible relation which exists between the works published by Berthelot and those which were available for his study if he had cared to make a search.

To sum up :—

(1) Berthelot made no attempt to study the whole field of Arabic chemistry—an important fact which has, as a rule, not been observed by historians.

(2) He neglected entirely the development of chemistry in Islam in its most flourishing period.

---

[12] *Ibid.*, p. 15.

[13] *Proc. Roy. Soc. Medicine*, October, 1923.

(3) He confined his attention to three points, (*a*) Arabic originals of Latin works, (*b*) Greek influence, and (*c*) the works of Jābir and their relation to the Latin works of Geber.

(4) As regards (*a*), he made scarcely any addition to our knowledge. As regards (*b*), his choice of material was sufficient and he proved his point, although he did not exhaust the subject and his material might have been better chosen. As regards (*c*), he proved that the Latin works could not have been translated *from the Arabic works he published*, but he did not (α) prove that the Latin works were not based on Arabic originals, nor (β) did he give an adequate account of Jābir's knowledge, choosing only nine works out of some 80 available.

In the second article I shall deal with Berthelot's treatment of his material and with his conclusions, but meanwhile it has been made clear (1) that, as far as Arabic chemistry is concerned, he is not a safe guide, (2) that he touched only the fringes of the subject, (3) that his choice of material was extremely inadequate, and (4) that in the case of the one chemist of whom he made a professedly detailed study he gave a very inaccurate picture based upon a negligible fraction of the data which are available. This is a serious indictment, but I believe it to be made with justice and to be based, as I have tried to show, upon irrefragable evidence.

(*To be continued.*)

FORTHCOMING EVENTS

Oct. 10. UNIVERSITY OF LONDON, University College, Gower Street, W.C., at 5 p.m. "The Heating Equipment of a Small House." By A. H. Barker.

Oct. 12. INSTITUTE OF BREWING. Joint Dinner of the Gloucestershire Brewers' Association and the London and Midland Counties' Section of the Institute at the Royal Hotel, Bristol, at 7 p.m. Meeting at 8 p.m. (1) "The Quick-Chilling Process," by A. Hadley. (2) "The Slow-Chilling Process—Maturation and Chilling in Tanks," by P. K. Le May. (3) "The Slow-Chilling Process—Maturation and Chilling in Cask," by H. Abbot, M.A.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS,

October 31, 1923

This dinner is being held under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry at the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on October 31, at 7 for 7.30 p.m.

The details are being arranged by a committee consisting of representatives of the three societies mentioned above and one or two other societies. The price of the tickets for ladies or gentlemen is 12s. 6d. each, not including wine.

Sir William Pope, K.B.E., F.R.S., will take the chair. There will be some speeches and some music; it is thought that both these will be of interest, and that there will be in addition opportunities for informal talk.

No similar dinner for chemists has hitherto been organised on exactly these lines, and it is expected that such a gathering will be not only very pleasant, but will be useful in promoting that social acquaintance which is so valuable in connexion with prevailing ideas and hopes. Members of any of the societies concerned are invited to attend and to bring guests.

Applications for tickets should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C.2.

SOUTH WALES SECTION

The following are the arrangements for the coming Session, 1923-24:—On October 12, 1923, discussion on the "Smoke Problem," to be opened by H. J. Bailey, O.B.E.; Thursday, November 8, dinner and address by Dr. E. F. Armstrong on "The New Chemistry"; December 7, a paper on "Coke Ovens," by T. G. Watts, B.Sc.; January 11, 1924, kinematograph exhibition and paper on "Cocoa," by H. W. Bywaters, D.Sc.; February 8, discussion on the "Action of Acids on Metals," to be opened by H. W. Webb, M.Sc.; March 7, paper on "Metal Colouring," by E. A. Rudge, B.Sc. These meetings will be held at Cardiff in the Technical College, Cathays Park, at 7.30 p.m. The following meetings will be held at Swansea in the Technical College, Mount Pleasant, at 7.15 p.m.:—October 19, 1923, Joint meeting with South Wales Section of the Institute of Chemistry; discussion on "Short Cuts in Analysis." November 16, 1923, Paper by E. A. Tyler, M.A.; January 18, 1924, Papers will be read (1) "Routine Work in an Oil Refinery Laboratory," by T. D. Ambrose, B.Sc., (2) "Estimation of Sulphur in Petroleum," by Dr. H. B. Thompson; February 15, Paper by Messrs. L. Taverner and H. J. Williams; March 14, Joint Discussion with the Faraday

Society on "Slags and Fluxes in Melting and Refining," with reference to the problems of slag inclusions; March 28, Annual Meeting, address by the chairman, Capt. H. Vivian.

BIRMINGHAM AND MIDLAND SECTION

There was a very large attendance of industrial chemists and gas engineers at the joint meeting held with the Midland Junior Gas Association, on September 25, at the Conference Room of the National Gas Exhibition, then being held at Bingley Hall, Birmingham. Dr. E. B. Maxted presided.

Mr. G. Coles, B.Sc., of the Mining Research Laboratory, read a paper on "The Specific Heat of Coal and Relation to its Composition," in which he gave the specific heats of various British coals, in the dried and undried condition, and classified them according to the different types of coal investigated. It was concluded that the specific heats of coal generally lay between the values 0·2 and 0·4, according to the water content of the coal. The nature and general composition of the coal also influenced the value of the specific heat, and, when the latter was reduced to an ash-free dry basis, coals of the same class possessed values of the same order for their specific heat. Anthracites and fusains agreed fairly well with Kopp's law, but bituminous coals diverged from this by about 11 per cent.

A new gas combustion-furnace was described by J. Hedley, who pointed out that existing types of furnaces represented little or no advance in design or efficiency over those in use over half a century ago, and were usually expensive, heavy and very wasteful. The new furnace was readily portable by one person, cost considerably less than any other furnace, was economical of gas, and could be operated with precision and comfort. The essential features were a multiple flame burner with separate control of each flame, gas being admitted at each end of the burner (which was partitioned at the centre) by a series of jet holes, the number in use being controlled by a screw plunger. The burner was self-regulating, the air intake by induced draught being governed by the number of jets in use; by this means any type of flame could be obtained for any number of flames, the number of flame orifices open being varied from the front underneath the burner by simple heat-screened thumb-screw valves. Adequate provision was made for the protection of the operator, the bench and the bungs of the combustion tube, by suitable hinged and fixed refractory screens.

A third paper, entitled "A New Automatic Pressure and Temperature Corrector for Gas Volumes," was contributed by Mr. C. H. Beasley. The design of the Beasley Recorder manufactured by Messrs. Parkinson and W. & B. Cowan had been improved, particularly in the device for measuring gas. The meter water line was now kept to a constant level by a small storage tank holding enough water to keep the meter correctly lined for several days without attention, and a constant drip of water was supplied from the storage tank to the meter slightly in excess to that required to meet losses by evaporation and conditions of saturation of the gas passing. The gas control to the instrument was effected by a pendulum-controlled clock escapement to the meter drum, by which the volume passed was kept constant irrespective of temperature, barometric pressure or density changes. By means of a flat steel "brake" spring, the pendulum rate of oscillation could be automatically varied in direct proportion to the alteration of volume of the gas passing through the meter owing to temperature and pressure conditions. This mechanism was practically frictionless, the brake spring being carried at the end of an arm of a lever operated by a set of fluxing diaphragms, forming part of a vessel containing a locked amount of air in the presence of water. The vessel itself and also the diaphragms were in contact with the gas stream and took up the same temperature. The diaphragms and lever thus moved in accordance with changes of pressure in the air vessel or external atmospheric pressure changes. The volume of the air chamber being large in proportion to that of the fluxing capsules, the movements obtained by changes of pressure were closely proportioned to the magnitude of these changes so that the brake spring moved distances proportional to the pressure changes.

The stud at the end of the brake spring came in contact with the sides of a taper slot made in a thin metal plate, forming the upper part of the pendulum rod. The slot was a section of the arc of oscillation, and the end of the brake spring moved vertically up and down the slot, its position being determined by the movements of the capsules expanding or contracting with changes of volume of the trapped air and water vapour in the air vessel. Whatever part of the slot the spring was in the extent to which it was bent remained the same; consequently its opposing force was constant in amount, and by applying this opposing force the pendulum rates were proportional to the distances the brake moved to and from a given position. This given position was the zero, the point in the slot where the brake spring rested when temperature and pressure were normal. If the brake moved below this point, the pendulum rate was increased; if it went above this point, the rate was retarded by amounts proportional to the pressure and temperature changes.

For convenience of checking the position of the brake from its zero position a scale graduated in percentage of increase and decrease was fixed to the front of the meter, and the position of the index showed the amount to apply to the rate to get normal conditions.

CORRESPONDENCE

"THE DETERGENT ACTION OF SOAP"

Sir,—The results obtained by Prof. McBain and his colleagues on the "Detergent Action of Soap," published in the *Journal* recently, are of great interest, but there is no evidence in the paper that the materials used were pure, and if this was not ascertained the results will be doubtful to that extent.

It is mentioned that "Kaulbaum's Pure" materials were used, but recently I had occasion to use some pure oleic acid and obtained some of Kaulbaum's, which was far from pure (although charged at a high price) and useless for our purpose. A replacement was of similar inferior quality.

It would be interesting to know if the materials used by Prof. McBain were fully examined for purity before using.—I am, Sir, etc.,

London, "Raybell"
Sept. 22, 1923

THE FINISH OF CHEMICAL GLASSWARE

Sir,—In reference to a letter under the above heading in your issue of September 21, it may interest some of your readers to know that glass apparatus can be easily and rapidly ground down by hand on any suitable stone if only a solution of camphor in turpentine be used as a lubricant. Glass tubing, such as is used for bomb furnace work, can be cleanly cut through by pressing a sharp, triangular file, well lubricated with the camphor solution, against the tube and rotating the latter by hand. When the tube has been cut through at one point it readily breaks across the line of the groove.—I am, Sir, etc.,

H. V. Thompson
Chemistry Dept., Central School of Science
and Technology, Stoke-on-Trent
Sept. 25, 1923

THE ORIGIN OF SYMBOLS

Sir,—Your correspondents whose letters referring to the use and origin of symbols appeared in your issues of September 7 and 28, will probably find matter of considerable interest if they refer to the *Transactions* of the Chemical Society, 1923, pp. 939-946.

The reference quoted is to the Presidential Address of Sir James Walker, whose subject was "Symbols and Formulæ," and who traced the beginnings of the present system of elementary symbols back to the latter end of the eighteenth century. Should your correspondents wish to investigate the matter still further backward, they might consult a book entitled "Die Geheimsymbole der Chemie und Medizin des Mittelalters," published in 1900. A copy of this work is in the Library of the Chemical Society and may be borrowed under the usual regulations.—I am, Sir, etc.,

Chemical Society, F. W. Clifford
Burlington House, W.1.
September 29, 1923

PERSONALIA

At the meeting of the American Chemical Society in Milwaukee, the Priestley Medal was bestowed upon Prof. Ira Remsen, in recognition of his outstanding achievements in chemistry.

Recent promotions in the Legion of Honour are as follows: Monsieur Calmette (assistant director of the Institut Pasteur) to Grand Officier; Messieurs M. Borrel (Institute of Hygiene, Strasburg), Gayon (University of Bordeaux), L. Martin (Institut Pasteur), René Vallery Radot (son-in-law of Pasteur), to Commanders; and Messieurs Fernbach, Fourneau, Mesnil, and Marie (Institut Pasteur), to Officers. Monsieur Duclaux (Institut Pasteur) has been appointed Chevalier. These awards have been made to commemorate the centenary of Pasteur.

Dr. Edgar F. Smith, provost-emeritus of the University of Pennsylvania and past-president of the American Chemical Society, has been made an Officer of the Legion of Honour of France.

Prof. F. Gowland Hopkins is retiring from the Medical Research Council under the provisions of the Royal Charter governing the rotation of membership. The vacancy will be filled by Sir A. Garrod, professor of medicine at Oxford.

* * *

We regret to announce the death of Prof. H. McLeod, F.R.S., aged 82. After working under Hofmann and Frankland at the School of Mines, he held the chair of chemistry at Cooper's Hill for 30 years, and was president of Section B (chemistry) of the British Association in Edinburgh in 1892. He undertook the great labour of editing the Catalogue of Scientific Papers published by the Royal Society.

From Germany the deaths are announced of Prof. P. Friedländer, privat-dozent for organic chemistry and technical organic technology in the Technical Hochschule at Darmstadt, who was well known for his investigations on the chemistry of dyestuffs and for his work "Fortschritte der Teerfarbenfabrikation," in twelve volumes; of Dr. T. Kempi, formerly a director of the Chemischen Fabrik auf Aktien vorm. E. Schering, and a pupil of Landolt and Kolbe; of Prof. A. Stutzer, formerly professor of agricultural chemistry in the University of Konigsberg, who had carried out extensive researches on nitrifying and denitrifying bacteria, soil organisms, and sulphite-cellulose lyes; of K. Heidenreich, director of the Deutschen Verein von Gas- und Wasserfachmännern; of E. G. v. Höveling, founder of the Hamburg Schiffsbodenfarbenfabrik; of Dr. F. Evers; of Prof. B. Rathke, formerly hon. professor of chemistry in the University of Marburg; and of Prof. H. Geitel, who had devoted much time to work on radium.

NEWS AND NOTES

UNITED STATES

A New Ethylating Agent

For some time past the Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa., in connexion with the work of the Multiple Industrial Fellowship, sustained by the Carbide and Carbon Chemicals Corporation of New York, has been making a thorough investigation of the properties and uses of diethyl sulphate as a general ethylating agent. Mr. A. R. Cade, an Industrial Fellow of the Institute, under whom the greater part of the work on this subject has been carried out, has published recently in *Chemical and Metallurgical Engineering* a report on the investigation, which shows diethyl sulphate to be a most satisfactory general reagent for introducing ethyl groups into organic compounds. The Mellon Institute will be pleased to furnish samples of this material to anyone interested, and Mr. Cade will correspond gladly with anyone who desires further information upon this subject. Reprints of the article referred to above may be obtained by writing to Mr. Cade at the Institute.

Bauxite and Aluminium in 1921

Bauxite.—The quantity of this mineral marketed in the United States in 1921 was 889,800 long tons, a decline of 73 per cent. from that of 1920 and about one-fifth of the peak production of 1918. This decrease is due to the bauxite miners of the United States being compelled to curtail their operations in 1921 owing to the stagnation in the industries that use bauxite as a raw material; but it was reported that late in 1921 there was some revival of business, and that the bauxite mines were being put in shape for larger operations. A total of 91,700 t. of bauxite was used for making aluminium, 41,000 t. for chemicals and 6850 t. for abrasives. Imports amounted to 27,587 t., exports were 5942 t., and the apparent domestic consumption was 161,195 t.

The world's output of bauxite in 1921 was :—United States 141,790 metric tons, France 84,942 t. (unofficial), and Italy 49,100 t. (including Istria). The figures for the United Kingdom are not yet available.

Aluminium.—The production of aluminium in the United States in 1921 was valued at \$14,681,400, the imports at \$8,889,791, and the exports at \$3,108,857. The apparent consumption was \$20,462,300, a decrease of over 37 million dollars. It was not found necessary to change the domestic plants, except to limit the output, which was done. It is reported that the Aluminium Co. of America has plans for a new development of power near Long Sault Rapids, New York. Apparently no changes in the status of the British aluminium industry took place during 1921, except the formation of a mining company to develop deposits in British Guiana.

Aluminium Salts.—The production of aluminium chemicals decreased in 1921, as compared with 1920, though the decrease was not so great as in some of the products made from bauxite. The quantity of aluminium chemicals made and sold during 1921 was 184,820 short tons, valued at \$7,546,000 ; chloride, made at five plants, amounted to 5650 t., and sulphate, made at 19 plants, amounted to 154,920 t. ; 3060 t. of commercial aluminium sulphate was made at municipal waterworks in 1921.

GENERAL

Metal Statistics, 1919–1921

Following the series of pamphlets on the sources, production and consumption of metals and non-metallic minerals, the Imperial Mineral Resources Bureau has now issued through H.M. Stationery Office further publications, wholly statistical, dealing with the following metals during the period 1919-1921 : *Copper* (70 pp., price 3s. net), *Zinc* (60 pp., price 2s.), *Lead* (56 pp., 2s.), *Silver* (38 pp., 1s. 6d.), *Gold*, (42 pp., 1s. 6d.).

Each publication gives a table of average rates of exchange for the period, the world's production of the ore, details of the production of silver in the principal producing countries, summaries of exports and imports and monthly average prices.

The following figures show the world's smelter production of metal for the years covered by the publications :—

	1919	1920	1921
Copper, long tons	937,000	947,000	580,000
Zinc ,, ,, ..	645,000	705,000	432,000
Lead ,, ,, ..	829,000	886,000	849,000
Silver, fine oz. ..	89,328,000	87,037,000	85,172,000
Gold ,, ..	14,333,000	13,516,000	13,401,000

Mineral Production of Southern Rhodesia in 1922

The total value of minerals produced in Southern Rhodesia in 1922 was £4,474,583 (£4,720,375 in 1921), the principal item being gold, the output of which amounted to £652,791, valued at £3,111,468, an increase of 67,266 oz. over the output in 1921. There was a decrease in value of £105,807, owing to the fall in the gold premium. The output of silver totalled 172,209 oz. (£24,526), an increase of 19,220 oz. (£4685) over 1921. The following shows the amount and value of the output of various minerals, the figures in parentheses referring to 1921 :—Asbestos, 14,249 tons, £577,699 (decrease of 5280 t.) ; chrome, 93,475 t., £302,880 (increase of 43,287 t.) ; coal, 515,650 t., £225,345 (decrease of 59,103 t.) ; copper, 3388 t., £201,022 (3080 t.) ; mica, 66 t., £16,561 (decrease of 19 t.) ; arsenic from the Buluwayo and Umtali districts, 497 t., £11,774 (361 t. at £11,263) ; diamonds, 256 carats, £1643 (141 carats at £720). It is stated that the existence of a seam of good steam coal, averaging 28 feet thick, has been proved in borings put down over a large area around a new site.

REVIEWS

Physikalisch-Chemische Tabellen. *By* Landolt-Börnstein. *Fifth and enlarged edition, edited by* Profs. W. A. Roth and K. Scheel, *and numerous other collaborators. Vol. I. Pp. xv+784. Vol. II. Pp. 784-1695. Berlin: Julius Springer,* 1923. *Price* 187*s.* 6*d.*

Konstanten der Atomphysik. *Edited by* Prof. W. A. Roth, Prof. K. Scheel and Prof. E. Regener. *Pp.* 114. *Berlin: Julius Springer,* 1923. *Price* 8*s.* 4*d.*

Every worker in physics and chemistry will welcome this new edition of the famous Landolt-Börnstein Tables—except, perhaps, those who may have recently purchased the 1912 edition. For this fifth edition is not only the fourth brought up to date but in many respects the book is remarkably improved. The work is produced in two volumes of more handy size than the former bulky tome: the first volume is supposed to contain chiefly chemical data and the second physical, but no clear distinction can be made. The index at the end of Volume II could have been conveniently included in each volume. The present index is, however, a considerable improvement on that of the former edition, which was inadequate. Each section of the Tables appears to have been recast. Not only have the latest values been introduced, but unnecessary and less accurate data have in some cases been removed, thereby enhancing the critical value of the Tables and rendering them less cumbersome.

The arrangement and printing are improved and graphs are used as much as possible—for example, in the section on resistance of alloys. When graphs are given it would be an improvement if the special data illustrated, *e.g.*, eutectic points, were also always given numerically; this is done in many cases, but not universally. One notices that many of the freezing-point diagrams given in the last edition have been redrawn in view of later work.

The Tables are thoroughly up to date—there is even mention of element number 72. The inclusion of comprehensive data for X-ray spectra, crystal structure as elucidated by X-ray analysis, dimensions of molecules, radioactive constants, series spectra, ionisation data, etc. greatly increases the value of the Tables. Particularly important is the section dealing with radiation constants, in which the many recent determinations of Planck's, Wien's constants, etc., are brought together, the accepted value being printed in bolder type, full references being given, as well as notes as to the method and the corrections applied.

These new physical sections are also printed separately in a much smaller volume entitled, *Konstanten der Atomphysik,* and many will find the book useful.

The section on specific heat in the larger volume is considerably extended to include recent work, but a table of accepted values of characteristic temperatures (βv) and of the differences of specific heat for constant pressure and volume might well have been added.

The Tables have lost both the originators (Prof. Börnstein died in 1913), but Prof. Roth and Scheel are to be congratulated on the way in which they have carried on this monumental work.

One cannot conclude this review without inquiring for a moment into the whole position of the work of recording data relating to the chemical and physical sciences. First there is the publication of the work, then the hunting out of the new facts and data, and finally their record in suitable form for reference.

It is difficult enough to lay hands on original communications in any particular line of work, but somehow we contrive to make it unnecessarily troublesome. Journals multiply and the range of subjects which they accept increases. One year papers of a certain type will appear in the *Annalen der Physik,* the next year finds them in the *Zeitschrift fur Physik* and so on. It would be much more convenient if each country decided to publish a certain class of work in a certain journal. The hunting out of the data is a matter of organisation. In the case of the Annual Tables of Constants, the journals are searched for numerical data by an abstractor in each country, marked in subjects and sent to a central depot, from which each collection of similar subjects is sent to a specialist to edit the particular section. In the same way it would be possible to search the journals for any subject (*e.g.,* "methods of preparation"), and make a complete subject bibliography.

Finally, there is the record of the data so gathered. "The International Annual Tables" aim at producing a complete record of all numerical data as published from year to year, so that reference to the tables gives every measurement which has been published on the subject since a certain date, 1910. The Annual Tables become almost a reference library in themselves in this way, and the data so collected form a complete record of progress. "The Critical Tables," which are in course of being produced in America with the collaboration of other countries, under the auspices of the International Research Council, critically survey the data collected by the Annual Tables and provide authoritative figures for as many constants as possible. So far as one can judge, the Landolt-Börnstein Tables take their position between the forthcoming International Critical Tables and the complete Annual Tables. They do not include all data like the Annual Tables, but they include data previous to 1910 which the Annual Tables naturally are not intended to contain; neither are they strictly critical, nor do they include technological or biological data, which are published in the Annual Tables and will be contained in the Critical Tables.

B

One may remark in conclusion that it is a pity that international collaboration in these matters is no longer complete since the war. But we may apply to these books, the prophecy of Lionardo da Vinci: "Men shall speak with and touch and embrace each other while standing each in different hemispheres, and shall understand each other's language"—but, perhaps, the quotation applies better to the latest developments of wireless.

A. C. EGERTON

PRACTICAL BACTERIOLOGY FOR CHEMICAL STUDENTS. *By* D. ELLIS, Ph.D., D.Sc., F.R.S.E. *Pp. viii*+136. *London: Longmans, Green and Co.*, 1923. *Price* 4*s*. 6*d*.

In perusing this book we find that much useful space is occupied by illustrations of pieces of apparatus which require no pictorial representation. It should be unnecessary, in a text-book concerning bacteriology, to depict for chemical students Ehrlenmeyer flasks, the top of a dropping bottle, or a watch glass supported by a pipe-clay triangle on a tripod stand. Adequate representation might have been made, however, of some of the more common organisms in everyday work; and Figs. 36 and 37 appear to be missing.

The section dealing with the preparation of culture media is poor and lacking in finish. Thus, gelatin is given priority of place, but it is very rarely used in many bacteriological laboratories examining thousands of specimens a year. No mention is made of up-to-date methods of standardising media, or the optimum reactions for various organisms obtained by estimating the hydrogen-ion concentration of the media, and the preparation of the various sugar peptone media is wrongly described. In preparing the last-named media, broth should *not* be used as a basis since minute traces of glucose from the meat may upset the sugar reactions; only sugar-free peptone should be used.

Prof. Ellis is apparently of the opinion that low-power lenses can be used for bacteriology. In the section dealing with the examination of a wet preparation of bacteria we must confess to a feeling that Prof. Ellis is very much of an optimist if he is able to distinguish cocci with the microscope working at a magnification of 350 diameters.

More detailed reference to the use of oil-immersion objectives would have been desirable.

In an elementary text-book of bacteriology we do not want to know that the author "has found glycogen in *Cladothrix dichotoma* among the Iron bacteria," but we do require accurate information regarding technique. For instance, in regard to Gram's method of staining—the most important of all methods of staining in bacteriology—Prof. Ellis gives the routine method but entirely forgets to counterstain his film after decolorisation. What the student will see with a Gram-negative preparation is best left to the imagination.

Too much attention is given to *B. megatherium*, which is not of great consequence in routine bacteriological work, and by working with this organism the real difficulty of bacteriological technique is by no means met.

There is no reference—in the index, at all events—to ultra-microscopic methods of examination by dark-ground condensers, or to the bacteriological testing of disinfectants or antiseptics.

On the whole, the book leaves much to be desired, and we confess that we do not think it is likely to be of very great value to the chemist who desires to obtain a sound working knowledge of bacteriological methods.

ARNOLD RENSHAW

CHEMISCHE TECHNOLOGIE DES STEINKOHLENTEERS, MIT BERÜCKSICHTIGUNG DER KOKSBEREITUNG. *By* Dr. R. WEISSGERBER. *Pp. vii*+141. *Leipzig: Otto Spamer*, 1923. *Price, paper* 4*s*. 2*d*., *bound* 6*s*.

A very hearty welcome may be accorded to Dr. Weissgerber's clear and concise account of the chemical technology of coal-tar distillation, etc., contained in the book under review. Within the space of little more than 100 pages, the author has succeeded in giving an adequate account of the German coal-tar industry, so far as this relates to the manufacture of the ordinary commercial coal-tar products, and also of such pure or nearly pure products as are ordinarily made at the larger tar-works. Throughout the whole of the book, one is conscious of the author's intimate practical acquaintance with his subject, and it is difficult to see how, within the limits of the space allotted, a greater amount of information could be supplied. Naturally, with that limitation, only short and general descriptions of the actual plant employed can be given, but the essential points of these are indicated in a manner which will be clear to anyone familiar with chemical works plant in general.

Due consideration is given throughout to the commercial as well as the technical side of the industry, to the alterations in the character of the crude tar, to the changes in requirements for the products which have taken place during the past 50 years, and especially those due to war and post-war conditions. Some account is also given of the preparation of the various "substitutes" obtained from coal-tar during the latter period, such as the coumarone and indene resins, lubricating oils, etc.

The first 30 pages of the book are given up to a short description of the chemical properties of coal, and of the different carbonisation industries which lead to the production of crude coal-tar. These descriptions are in no way exhaustive, but are intended to bring out such points as are of especial importance from the standpoint of the subsequent working-up of the coal-tar produced. They include a summary of the present position of the low-temperature carbonisation of coal, as now practised in Germany for the primary purpose of increasing the "internal" production of crude oil.

From the point of view of those actually engaged in the coal-tar industry, probably the main regret felt will be that Dr. Weissgerber, owing to the limits of space set by himself, or by the publisher, was unable to go still further into manufacturing details, which, with the author's great knowledge, would have further enhanced the value of the book. But even without this, and allowing for the fact that present trade conditions here differ considerably from those prevailing in Germany, the book is one which should be in the hands of all concerned with the coal-tar industry, and for other chemists who wish to obtain an insight into the methods of the industry, the book as it stands will be invaluable.

H. G. Colman

Auskunftsbuch für die Chemische Industrie. *By* H. Blücher. *Vol. I. A-L. Pp. xiv*+840. *Vol. II. M-Z. Pp.* 841—1672. *Berlin: W. de Gruyter and Co.,* 1923. *Price* 11*s. each volume,* 22*s. the two volumes.*

The nature and scope of this work of reference were fully described in the notice of the 11th edition (*cf. J.*, 1922, 65 R). The present edition contains an additional 82 pages, and has been thoroughly revised and brought up to date. The work is primarily intended to be of service to German chemists and manufacturers, and the choice of material has been largely influenced by Germany's present necessity of utilising her internal resources to a much more exhaustive degree than formerly, owing to the prohibitive cost of imported products. Considerable progress, for example, is reported in the utilisation of slags and other hitherto despised wastes and by-products, and also in the economical distillation of coal.

In this edition, removed a little farther than the last from the war period, it has been possible to value more exactly a large number of "substitute products" in use during the war, and to indicate with greater certainty those which are likely to have any permanent value.

Although the author complains that the high price of foreign books and journals in Germany has rendered it necessary for him to draw in many cases from reviews and abstracts instead of the original sources, the information given is accurate and, for a book of reference, complete. That the work has met with the appreciation of those for whom it is intended is shown by the issue of twelve editions in twenty-one years.

Reginald Brown

REPORTS

Report of the Government Chemist upon the Work of the Government Laboratory for the Year Ending March 31, 1923. *Pp.* 31. *H.M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

As the chemical work of most of the Government departments is performed mainly in the Government Laboratories, it covers so wide a range as to preclude adequate notice. The following notes are given to indicate the main points of interest.

During the year 343,454 samples were examined at the Government Laboratory and at chemical stations, an increase of 40,891 compared with 1921–22. This increase was due to the larger number examined of samples of wines, beer, spirituous preparations, sugar, and to extra work due to the Safeguarding of Industries, the Dangerous Drugs, and the Dyestuffs (Import Regulation) Acts.

A small number of samples of imported butter and margarine was found to contain excess of water, but no butter was adulterated with foreign fat, and the margarine never contained excess of butter. The proportion of fat in cheese was found to vary from 20·2 to 54·4 per cent. of the dry matter; some of the cheese had thus been made from skimmed milk, but no exception could be taken, as there are no appropriate regulations to control composition. It was found that the composition of condensed full-cream or "whole milk" varied very greatly; all the samples of condensed milk were free from chemical preservatives. An inquiry was made into the proposed standards for condensed milk and the character of filled milk powder.

The investigations on the effect of drainage from tarred roads on fish life showed that bituminous dressings appeared to be reasonably free from danger (*cf. Chem. and Ind.*, p. 544, 1923). Many samples of river water, effluents, and sea-water were examined.

Work on fertilisers revealed that most of the mixed fertilisers tested contained less than the guaranteed amounts of nitrogen, phosphates and potash, and various deficiencies and impurities in feeding stuffs were detected.

An inquiry was made under the Merchandise Marks Act into the composition of various agricultural materials, and it was found that 53 out of 71 samples of crystallised copper sulphate were 98 per cent. pure, 12 were almost up to this standard, and 2, sold as "commercial blue vitriol," consisted of mixtures of equal proportions of copper sulphate and ferrous sulphate.

Altogether, 32,542 samples of beer were examined for assessment of duty; of 308 samples as retailed 256 had been diluted. Only 1361 samples of imported beer were submitted. Out of 462 samples of brewing materials tested, 66 contained arsenic in excess of the legal limit.

Samples numbering 105 were examined

under the Dangerous Drugs Act, 633 under the Dyestuffs (Import Regulation) Act, and 8000 under the Safeguarding of Industries Act.

Many samples of duty-free spirits and denaturants were examined and progress was made in the inquiry into the characteristics of denaturants and colouring substances used for industrial alcohol.

As marking the production of beet sugar in this country, it is of interest to note that 50 samples of refined sugar, molasses, beet juice, and exhausted beet pulp were examined.

Work carried out for the Department of Scientific and Industrial Research included investigations into the nature of the aqueous extracts of wood, the value of anti-rust preparations, and the helium content of natural gas from boreholes in this country; the content was found to vary from 0·005 to about 0·2 per cent. by volume. Much work on building materials and paints, and on the preservation of ancient monuments was done for the Office of Works.

Report on the Economic, Commercial and Industrial Situation of Sweden, Dated March, 1923. *By* H. Kershaw, *H.M. Commercial Secretary, Stockholm. Department of Overseas Trade. Pp.* 68. *H.M. Stationery Office*, 1923. *Price* 2*s*.

During 1922 there was considerable recovery in Sweden from the period of economic dislocation noted in the last report (*Cf. J.*, 1922, 296 R). Although the record harvest of 1921 gave rise to hopes of an immediate recovery, these had to be abandoned and conditions adjusted to the trade depression and to the rapid deflation which continued uninterruptedly. Deflation has achieved its object of bringing down prices, which now approximate to those ruling in Great Britain and America, and optimism is now more general, especially due to the rise in the sterling exchange. The tremendous decrease in the excess of imports over exports in 1922 was a great achievement, but the approach to stable economic conditions has not yet ended. The question of wages and labour is a serious problem, and the strikes at the beginning of this year, together with the continued economic chaos in Central Europe, checked the growth of confidence in commercial circles. Nevertheless, the present stability of prices is a great help to national prosperity. The severity of German competition in Swedish markets has diminished, though the effect is not so marked in some lines—for instance, chemicals and drugs. Sweden depends largely on imports for supplies of coal, and it is noteworthy that of the 2,635,845 t. imported in 1922, no less than 95·5 per cent. was obtained from Great Britain. In addition to about 500,000 t. of coal produced in the country, 70,000 t. was obtained from Spitzbergen. The timber and wood trade was satisfactory in 1922, and prospects for 1923 are encouraging. The chemical pulp trade yielded indifferent results, though by reducing prices, possibly unprofitably, large stocks were disposed of in the United States and Canada. The output of sulphite cellulose in 1922 is estimated at 757,000 t., of sulphate cellulose at 249,000 t., and of mechanical wood-pulp at 310,000 t. Reduced costs of raw materials helped the china and pottery industry, and the output was about 75 per cent. of that of pre-war years. The Grängesberg Co. exported 5,361,772 t. of iron ore in 1922, against 3,472,352 t. in 1921; the prospects for 1923 are better still. Newly discovered copper deposits are expected to become important. The iron and steel industry was depressed, though less than in the previous year, and only 259,700 t. of pig-iron was produced, compared with 314,400 t. in 1921. Though 1923 opened badly, bigger export demands are anticipated. The leather industry seems to have recovered, and the match industry has been doing well, 29,343 t. being exported in 1922 (20,000 t. in 1921). The agricultural situation is unsatisfactory, and the general fall in sugar prices makes beet-growing unprofitable. Hydro-electric power generated in 1922 reached 1,269,000 h.p., and further developments are in progress.

The following figures give the value in kronor of the foreign trade in 1922 in some important groups of merchandise:—Tallow, oils, etc.—imports 67,674,527, exports 10,775,529; dyes and colours—imports 13,913,526, exports 744,726; wood-pulp, cardboard and paper—imports 16,113,105, exports 317,507,100; minerals (raw)—imports 148,292,079, exports 87,513,537; finished mineral products—imports 22,876,577, exports 61,850,524; metals (unmanufactured)—imports 42,779,672, exports 51,105,801; metals (manufactured)—imports 52,189,195, exports 51,993,754. Other imports included coal tar, 6287 t.; vegetable fatty oils, 8511 t.; vegetable fats, 5874 t.; zinc white, lithopone, baryta, 5196 t.; linseed, 26,466 t.; oil cake, 64,163 t.; tanning materials, 5871 t.; Chile saltpetre, 20,179 t.; coke, 528,338 t.; salt, 32,603 t.; Glauber's salt and sodium bisulphate, 50,582 t.; raw phosphates, 71,290 t.; soda, 14,169 t.; Stassfurt salts, 77,653 t.; coal, 2,635,845 t.; pyrites, 78,067 t.; sulphur, 58,346 t.; iron and steel, 92,745 t. The exports included:—Cement, 82,900 t.; felspar, 22,045 t.; iron ore, 5,321,914 t.; superphosphate, 20,311 t.

Prof. E. Heuser, director of the Institute for the Chemistry of Cellulose of the Technical *Hochschule*, Darmstadt, has been appointed director of scientific research to the Vereinigten Glanzstoffabriken in Seehof near Berlin.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Sept.* 27)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Artificial silk yarns	353
Belgium	Paper	333
British India	Leather	323
Canada	Rubber sheeting	326
Italy	Edible soya-bean oil, oil seeds, sesame seeds, groundnuts	336
Netherlands	Tinplate, tyres	338, 339
Norway	Pig iron, paper	341
Poland	Fertilisers	342
Rumania	Scientific apparatus	344
South Africa	Glassware	329
United States	Tiles, firebricks, etc.	20547/F.W. /M.C./2 20143/F.W. /M.C./2

TARIFF CUSTOMS EXCISE

Ecuador.—The current issue describes recent regulations for the control of the opium trade.

Fiji.—The export duty on copra is abolished.

Japan.—Import duties have been suspended on oils, boric acid, bicarbonate of soda, salicylate of soda, hydrogen peroxide, chloroform, iodoform, antipyrin, santonin, chemicals, medicines, leather, indiarubber, paper, building materials, iron, glass, gum and resin. The suspension dates from September 17, and is effective until March 31, 1924.

Madagascar.—Anthraquinone is now duty-free.

Poland.—The duty on acetic acid has been increased from 6000 to 12,000 P. mks. per kg. of undiluted acid.

Sierra Leone.—The exportation of gum copal[1] has been prohibited.

South Africa.—A dumping duty is levied on cement imported into Basutoland, Bechuanaland and Swaziland.

United Kingdom – Czechoslovakia — The agreement respecting Commercial Travellers' Samples has been ratified.

United States.—Cresol, asphalt and asbestos are dutiable.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Although the volume of business is disappointing there is a slight improvement in the position compared with that ruling during the last month or two. Salt cake is decidedly scarce and more export inquiries are being received. Other heavy chemicals are in steady request. Prices are unchanged, but from Oct. 1 ammonia alkali is reduced by 2s. 6d. per ton to £7 10s. per ton.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw.	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali	£7 10s. per ton, spot delivery. General export demand good, particularly from the Continent.
Arsenic (White)	£72—£73 per ton. Not much doing.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate	£25 per ton. Dull.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£25 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.

Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 9¼d. per lb. Less quantities 10½d. per lb. ex wharf London. Ample supplies.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb.
Lead Hyposulphite	8d. per lb.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur, finest	£10 10s. per ton.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

The volume of trade is small and, except in acetates, there is very little life. The tar market seems slightly weaker.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. Slightly weaker.
Brown Sugar of Lead	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 2d. per lb. Good demand. Market firmer. Limited quantities only available for prompt delivery.
Crude 60's	3s. 6d.—3s. 8d. per gall. Good demand for spot delivery.
Acid Cresylic—97/99	2s.—2s. 2d. per gall. Fair demand.
Pale 95%	1s. 10d.—2s. per gall. Market quiet.
Dark	1s. 7d.—1s. 10d. per gall. Fair parcels offered.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. Few inquiries but no business.
Anthracene Oil—	
Strained	10d.—11½d. per gall. Supply short.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	1s. 1½d. per gall.
Standard Motor	1s. 3d.—1s. 6½d. per gall. delivered buyer's works.
Pure	1s. 8d.—2s. 1d. per gall. d/d. buyer's works.
Toluole—90%	1s. 7d.—1s. 8d. per gall. Little business passing.
Pure	1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—10¼d. per gall. according to grade and district. Demand still good.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 3d.—1s. 6d. per gall. Market very quiet.
Solvent 90/190	1s. 3d.—1s. 4d. per gall. Market very quiet.
Naphthalene Crude—	
Drained Creosote Salts	£7 10s.—£8 per ton. More inquiry, difficult to meet demand.
Whizzed or hot pressed	£11—£12 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	120s.—130s. per ton, according to district and time of delivery. Several inquiries but sellers not anxious.
Pyridine—90/140	21s.—21s. 6d. per gall. Market very strong. Price still advancing.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Business quiet and difficult. Buyers refuse to carry stock and buy from hand to mouth. Orders frequent but small. Textile trade slack and outlook not very promising.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 10d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 7d.—1s. 8d. per lb. Good demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/21° C.	5½d.—6d. per lb. Prices slightly reduced and a better demand is experienced.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/24° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.

Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50	8d.—9d. per lb. naked at works.
66/68	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 8d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb, 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Business is still quiet, but prices remain steady, Continental quotations being increasingly firm.

The demand for tartaric acid still continues to be poor owing to accumulation of stocks by both consumers and speculators. This is due to the cold weather during the first six months of the year, which was disastrous to the home trade and, as a consequence, speculators in foreign acid who were unable to get rid of their stocks, are offering at prices which are considerably below the cost of production in this country. Hence, although the demand has been slightly better during the past week or so, the market continues to be weak. It is reported that one forced sale of German acid amounting to 50 tons has been done at 1s. less 5% delivered here. This figure is below the immediate pre-war price.

The imports of tartaric acid into this country for the month of August amounted to 56·15 tons, against 125·20 tons for the previous month. The export demand is still below normal and a price below the cost of production must be accepted for any business that is done. Italy is, at present, our principal competitor in both the home and export markets. We are of the opinion that the bottom has now been reached and this is confirmed by the fact that both consumers and distributors seem anxious to enter into contracts for forward delivery over next year at the low prices that are now prevailing.

Acid, Acetic 80% B.P.	£52 10s. per ton.	
Acid, Acetyl Salicylic	3s. 1d.—3s. 2d. per lb. Good demand. Firm market. Price likely to advance owing to increase in raw material.	
Acid, Benzoic	2s. 3d.—2s. 6d. per lb. Firmly held.	
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.	
Acid, Citric	1s. 6¼d. per lb., less 5%. Poor demand. Market dominated by weak holders and bad season.	
Acid, Gallic	3s. per lb. for pure crystal.	
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb., according to quantity.	
Acid, Salicylic	2s. 2d.—2s. 3d. per lb. for 5 cwt. lots. Firm market. Good inquiry. Supplies not heavy.	
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Fair business. Price steady.	
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Demand fair and likely to improve. Raw material dearer. Prices will probably advance. (*See introductory remarks.*)	
Amidol	9s. per lb. d/d.	
Acetanilide	1s. 6d. per lb. for English manufacture. Imported quoted at higher prices.	
Amidopyrin	12s. 6d. per lb. Demand still very poor.	
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.	
Ammon. Carbonate B.P.	£32 15s. per ton.	
Atropine Sulphate	12s. 6d. per oz. for English make.	
Barbitone	17s. per lb. for quantity. Demand limited.	
Benzonaphthol	4s. 6d.—4s. 9d. per lb. Slight advance in price.	
Bismuth Salts	A steady market. Prices unchanged.	
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.	
Bromides—		
Potassium	6½d. per lb.	Market unsettled. Poor demand. Potassium bromide easier in price; other salts unchanged.
Ammonium	7d. „ „	
Sodium	7½d. „ „	
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.	
Chloral Hydrate	3s. 9d.—4s. per lb. Somewhat firmer. English makers are oversold.	
Chloroform	2s. 2d. per lb. for cwt. lots. Demand is poor.	
Creosote Carbonate	8s. lb. Demand negligible.	
Formaldehyde 40%	75s. per cwt. ex wharf London. Slightly less for large orders.	
Guaiacol Carbonate	8s. 6d. per lb.	
Hexamine	3s. 6d.—3s. 9d. per lb. Spot parcels have been cleared, and forward prices are higher.	
Homatropine Hydrobromide	30s. per oz.	
Hydroquinone	3s. 3d.—3s. 6d. per lb. Now asked, according to quantity and holder. British make cheaper than imported.	
Iron Ammon. Citrate	2s. 5d. per lb. for cwt. lots. Better demand.	
Magnesium Carbonate—		
Light Commercial	£37 per ton net.	
Magnesium Oxide—		
Light Commercial	£82 10s. per ton, less 2½%.	
Heavy Commercial	£28 per ton, less 2½%.	
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.	

Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Market somewhat easier owing to lower prices for mercury.
Methyl Salicylate	2s. 4d.—2s. 6d. per lb. Distinctly firmer for English or imported, in view of seasonal advance now in progress.
Methyl Sulphonal	14s. 6d. per lb. Easier.
Metol	8s. 9d. per lb.
Morphine and Salts	Prices advanced about 6d. per oz., due to higher price of opium. Alkaloid : Cryst. 11s. 6d., Precip. 11s. 3d., Acetate 9s., Hydrochlor. 9s., Sulphate 9s. per oz.
Paraformaldehyde	3s. 5d. per lb.
Paraldehyde	1s. 5d. per lb. Average price in 5 lb. bottles.
Phenacetin	6s.—6s. 3d. per lb. Demand and price steady.
Phenazone	7s.—7s. 3d. per lb. Firm.
Phenolphthalein	6s. 3d.—6s. 6d. per lb., according to quantity and holder. Rather more inquiry.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	2s. 8d. per lb. English makes are meeting foreign competition.
Potass. Iodide	15s. 8d.—16s. 2d. per lb. Good demand.
Potass. Metabisulphite	8d. per lb.
Potass. Permanganate	10d. per lb. for B.P. crystal. It is understood that English makers will soon resume operations.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 3d.—5s. 6d. per lb. Business moderately good.
Salol	3s. per lb. Limited demand. Price would be shaded for quantity.
Silver Proteinate	10s. per lb. A weaker market.
Sod. Benzoate	2s. 6d. per lb. Improved demand would lead to higher prices as present stocks cannot be replaced at current figures.
Sod. Citrate, B.P.C. 1923	2s. 3d. per lb.
Sod. Hyposulphite—Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—87s. 6d. per cwt. Fairly good demand.
Sod. Salicylate	Powder 2s. 6d.—2s. 7d. per lb., and Crystal at 2s. 8d. per lb. Firm, with tendency to rise.
Sod. Sulphite, anhydrous	£25—£26 10s. per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	14s. per lb.
Tartar Emetic	1s. lb. net. Fair demand.
Thymol	14s. per lb. for best white crystal.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate	3s. ,, ,,
Cinnamic Aldehyde Natural	18s. 6d. ,, ,,
Coumarin	18s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	10s. ,, ,,
Geraniol (Palmarosa)	35s. ,, ,,
Geraniol	5s. 6d.—12s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. per lb.
Linalol ex Bois de Rose	18s. 6d. ,, ,,
Linalyl Acetate	21s. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,, Cheaper.
Methyl Benzoate	6s. ,, ,,
Musk Ketone	40s. ,, ,,
Musk Xylol	12s. 6d. ,, ,,
Nerolin	3s. 3d. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,
Rhodinol	45s. ,, ,,
Safrol	2s. ,, ,,
Terpineol	3s. ,, ,,
Vanillin	22s. 6d.—23s. 6d. per lb. Fair and steady demand. Raw material dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. ,, ,,
Bergamot Oil	12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	35s. ,, ,,
Camphor Oil	80s. ,, ,,
Cananga Oil, Java	9s. ,, ,,
Cinnamon Oil, Leaf	4½d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 2d. ,, ,,
Ceylon	4s. ,, ,,
Clove Oil	8s. 6d. ,, ,,
Eucalyptus Oil 70/75%	2s. 8d. ,, ,,
Lavender Oil	18s. 6d. ,, ,,
Lemon Oil	2s. 10d. ,, ,,
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	24s. per oz.
Palma Rosa Oil	23s. 6d. per lb.
Peppermint Oil—	
Wayne County	15s. per lb. Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	7s. 6d. per lb.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, OCTOBER 12, 1923 No. 41

EDITORIAL

CHEMISTS are accustomed in the laboratory to study, not only the method of preparing a substance, but also the percentage of the theoretical yield which can be obtained under specified conditions, and in their writings we frequently meet with the phrases " optimum conditions " and " maximum output," which are useful ideas, though we are personally sometimes shy of a Latin adjective agreeing with an English noun. Probably every chemist is familiar with the conditions of manufacture on a larger scale than is practised in the laboratory, and he has no hesitation in stating that when a particular piece of plant, or a works, is fully employed so as to yield the greatest output which may be regularly expected, then the material may be manufactured more efficiently, or more economically, than in other circumstances. Those who motor know how many gallons of petrol ought to be required to drive their car or their cycle a hundred miles. Perhaps because such considerations are so familiar to them in their daily work, they sometimes ignore them in those leisure moments which they devote to the organisation of chemistry. But the essential principles are the same everywhere ; there is an ideal efficiency to be attained in a society, in a journal, or in so vague a conception as the organisation of a science such as chemistry. The relation between the expenditure of human energy, of time, or of money and the result, is as worthy of careful study as the percentage of the theoretical yield to be obtained in a new process for making potassium chlorate. To what extent has a thoroughly scientific investigation been made of this relation ? The whole question of chemical publications, books, abstracts, transactions and even ephemeral matter such as our own, requires close scrutiny, so that we can compare the actual achievements with the best standards to be obtained in practice. An even wider scrutiny might be made and a larger table of empirical constants collected, but the survey of the science as a whole is a thing imagination boggles at.

We are accustomed to the present circumstances ; either the institutions, with which we are most prominently identified, date back prior to our times, or we have ourselves taken an active part in their organisation and growth. In either case we have a pride in them, and an affection for them, and those who have been trained up in their methods and their mutual relations, will not gladly ignore the present and, instead, look at the whole available resources of chemistry, and see how the time, human ability and money now spent in rather a fortuitous manner, can be expended so as to produce the greatest result. Faraday wrote many years ago " a dislike to the trial arises ; but what is that except a proof, that whilst they trust themselves, they doubt themselves, and are not willing to proceed to the decision, lest the trust which they like should fail them, and the doubt which they dislike rise to the authority of truth." He was not thinking of such a broad view as we have mentioned, although such a man might " on the very border stand, of the blest promised land, and from the mountain top of his exalted wit," see it himself and show us it. But our times and circumstances are vastly different from what they were a few score of years or even ten years ago ; our predecessors were not troubled by our troubles, to them life was a simple art of duties to be done ; we have a set of burdens we shall not speedily shake off, black care perches on the back of the horseman's saddle. On the other hand, we have the chance of advancing pure and applied chemistry in a manner, and to a degree which was previously doubtful. Germany, once dominant in chemistry, is now distracted, and many of her great leaders are no longer living ; other countries have their problems as we have, but we have also a scientific opportunity which we dare not miss. The achievements of British chemists during the last generation have, as Dr. Levinstein has recently pointed out, been splendid, and those of the present generation will surpass them.

The circumstances which compelled the Society of Chemical Industry a year ago to consider the publication of their Journal weekly instead of twice a month are not circumstances which prevail in this country alone. Chemistry is not only vital to most of our industries, but the number of persons engaged in its study and its applications is so great that prompt circulation of items of news and fresh discoveries becomes more and more essential. Our American colleagues have this year circulated as a supplement to their journals a news sheet appearing at frequent intervals, and we are now interested to note that the Dutch Chemical Society has issued the first number of *Chemie en Industrie* as a supplement to its weekly journal, the *Chemisch Weekblad*. We wish the new enterprise every success and feel sure that the Dutch Chemical Society, which is already in many ways a model of efficient organisation, will achieve all that is possible. In the first number of *Chemie en Industrie* the following item appears :—"The Badische Aniline Co. in English Hands. It is rumoured that by large purchases of shares in German colour works by English and American financiers the majority of the Badische Aniline Co.'s shares have fallen into English hands." Such rumours must always be treated with caution ; the large German dyestuff companies have been managed by men of great talent who combined business ability with scientific knowledge. It is immaterial whether such men commenced with business or chemical training ; in middle life they were thoroughly well equipped in both.

In this country comparatively few men are both keen men of business and competent chemists. Those we have met have become prosperous, and it is singular how few have followed their example. Far too few of the wealthy, business, community have trained their children in chemistry, far too many men are educated as chemists with no ambition or no training to become important factors in the control of a business, where large sums of money are at stake. A man who has spent the most important twenty years of his life in the laboratory or the lecture room is not likely to have good judgment on matters of finance, on how to run a works, on questions of sales and purchases. But if suitable men are chosen in good time the desired result will be obtained. Dr. Duisberg said during the war "England talks not only of holding her own in the war, but of beating us in the organic chemical industry. She cannot do it because she is incapable of the necessary concentration, patience, and the faculty of fixing the eye on distant consequences, and not merely on monetary results." Everyone knows that we can do this if we make up our minds. Surely the prize is worth the struggle; the struggle is surely worth while irrespective of the value of the prize.

A CRITICAL EXAMINATION OF BERTHELOT'S WORK UPON ARABIC CHEMISTRY

By E. J. HOLMYARD

Part II

In the first article Berthelot's qualifications for the study of Arabic chemistry, and his choice of material, have been considered. It now remains for us to examine (1) his treatment of the material chosen and (2) the conclusions at which he arrived.

(I) Berthelot's Treatment of his Material

The manuscript material which Berthelot employed comprises 13 different works, of which nine are attributed to Jābir ibn Hayyān. The whole 13 occupy 205 pages of Arabic type and 180 in the French translation. In addition to the manuscripts, he had at his disposal (*a*) the catalogues of the chief European libraries, many of which contain valuable critical and bibliographical notes, (*b*) the *Kitāb al-Fihrist* in Fluegel's edition, (*c*) the Biographical Dictionary of Ibn Khallikan in English translation, (*d*) the *Prolegomena* of Ibn Khaldūn in French translation, (*e*) the *History of the Philosophers*, by Al-Qifti, (*f*) the *Classes of Physicians* by Ibn Abi Usaybiʿa, and (*g*) the celebrated bibliography, the *Kashfu'l-Zunun*, of Hajji Khalifa ; to name only those important sources to which one would naturally turn. Of the last six he claims to have used all except *e* and *f*, but it is clear from his book that whilst he has quoted the whole of the appropriate section of the *Fihrist* and much of the passage in Ibn Khaldun, he has not drawn very much from Hajji Khalifa, although a Latin translation of the *Kashfu'l-Zunun* was published by Fluegel many years previously (1838-1858). Of the catalogues of libraries he makes scarcely any mention and seems indeed to have neglected this valuable source of information.

The section of the *Kitāb al-Fihrist* (987 A.D.) dealing with alchemy was translated by Houdas and is given at pp. 26-40 of volume I. of *La Chimie au Moyen Age*. The *Fihrist* is of great value for the history of alchemy, as it gives a list of the early alchemists and the titles of many of their works, but Houdas' version is unprovided with notes or critical apparatus of any kind and contains several inaccuracies in translation and some very doubtful identifications. Thus *Afrāgasūs* is identified[1] with an uncertain *Africanus*, in spite of the fact that the latter name is in Arabic *al-Ifriqiyyu*, whilst the suggested identification[2] of *Arkaghanis*, as well, with *Africanus* has nothing whatever to recommend it.

In short, the data provided by the *Fihrist* have simply been thrust into the book without any attempt at digestion, and anyone who is carrying out research on the subject will get no assistance from Houdas' rendering. This, however, is perhaps beside the point, which is whether Berthelot himself found it useful. In so far as the passage had never been translated before, it was no doubt interesting and gave a bird's-eye view of the range of Arabic alchemy of the first three centuries of the Hijra, but its true value (which, as has been remarked above, is considerable) cannot be appreciated, nor can the passage itself be properly used, without a knowledge of a great many of the early alchemical works themselves. It is clear that Berthelot realised this, for he leaves the section entirely without comment.

---

[1] *La Chimie au Moyen Age*, III, 28.

[2] *Ibid.*, p. 35.

The other authorities are treated in the same cursory fashion, no attempt being made to arrive at a general idea of the course of Arabic alchemy, even up to the time of the Crusades, which was the limit which Berthelot set himself. Twelve pages of heterogeneous facts are, indeed, all that he appears to have extracted from the rich bibliographical sources he had immediately available. Even these facts are often incorrectly given. Thus there is no excuse for assigning Ibn Sina (Avicenna) to the twelfth century,[3] when the dates of his birth and death are well known to have been 980 and 1037 respectively; the date of the death of Al-Tughra'i, definitely given as 1122,[4] is in reality uncertain; Ibn Amyal (or better Umail) al-Temimi lived not in the twelfth century A.D.[5] but about 900 A.D.; Abn Casba ibn Temmam al-Iraqi[6] should be Abu'l-Asba; Djeldeik (rather Jildaki), placed between Ibn Hasan Ali (*i.e.*, Burhan al-Din Abu'l-Hasan Ali ibn Musa ibn Arfaʿ Ra's), who died probably in 1197, and Al-Ghazzali (died 1111), lived in the fourteenth century and died at Cairo somewhere about 1360. The famous controversy as to the reality of alchemy arose not in the twelfth century,[7] but in the first half of the ninth, in which period Yaʿqub-al-Kindi lived. Khālid ibn Yazid died in 704, not 708,[8] whilst the date of the death of Maslama al-Majriti[9] is not definitely known, and there is good reason to suppose that he never wrote on alchemy at all. Instead of its being the fact that "la plupart de ces traités (of Arabic alchemy) ont disparu,"[10] at least two-thirds of those mentioned by Hajji Khalifa in his article on *Alkimia* are still extant, although of course a great number of the very early ones have been lost. Of the list of 22 works quoted by Berthelot on pp. 41 and 42, about 10 are known in MS.

In dealing with the Latin works on alchemy ascribed to Avicenna, he has made a great many identifications which are, to say the least, very improbable; thus King Galud of Babylon is definitely identified with Khalid[11] without any reason given; Zucrat, obviously Suqrat, or Socrates, is surprisingly called Zoroaster; Clarō is given as "Caton"; Zabaibar appears to be identified with Vergil, for reason not given[12]; whilst Alpharabi, who is clearly Abu Nasr al-Farabi, is not identified. The "Jahie Abendinon" of Avicenna's list is unknown, but it has occurred to me that he may have been a son (Yahya) of the Egyptian alchemist and Sufi Dhu'n-Nun, and that "Jahie Abendinon" may be a crude translation of Yahya ibn Dhi'n-Nun. I do not know, however, whether Dhu'n Nun ever had a son, and I can find no trace of such a person as an alchemist. Dhu'n-Nun himself died in 860 A.D., so that his son would have lived in the ninth century, a date not incompatible with his inclusion in a list of Avicenna's.

It will be seen that Berthelot's introductory matter is meagre, that it has not been properly dealt with, and that it contains numerous inaccuracies which might easily have been avoided, and many doubtful identifications. It is, therefore, of very little help to a study of the manuscript texts themselves, and is often misleading. In other words, the published texts stand practically by themselves and have to be considered on their own merits, except for the light which Greek alchemy throws upon them. The manuscripts employed, especially the Leyden MS. 440, were not in a very good state, that volume, indeed, having been "mouillé dans sa partie inférieure," so that "les trois ou quatre dernières lignes sont souvent à moitié effacées, et parfois certains mots ont été complètement rongés par l'humidité." This rendered decipherment in many places uncertain, and in many others impossible. The major portions of the texts were, however, in good condition and the readings "presque toujours" certain.

The MSS. were transcribed by Houdas and printed in Volume III of *La Chimie au Moyen Age*, accompanied by a French translation as revised by Berthelot according to the peculiar canon mentioned in the previous article, namely, with the object of "making sense." Pages 9-23 give short descriptions of the treatises, together with a few notes. The annotations which accompany the translations deal almost entirely with resemblances of certain passages to passages of Greek alchemists, and the references are usually to the *Collection des Anciens Alchimistes Grecs*. In other words, Berthelot did not attempt the task of a proper elucidation of the translations, but confined himself to one definite point. This, as has already been said, he sufficiently proved; nevertheless, on the main question of the nature and development of Arabic chemistry he is perforce silent, and the historian will not derive much help in this direction from a perusal of the book. The works of Crates, Al-Habib and Ostanes, given by Berthelot, are indeed remarkable, not as being typical of Arabic chemistry, but because they are exceptional. I know of only one other MS. of "Ostanes'" treatise, and I have never come across a reference to those of Crates or Al-Habib in Jābir, Al-Razi, Burhan ad-Din ibn Arfa'Ra's, Abu'l-Qasim al-Iraqi, Ibn Sina, the pseudo-Maslama al-Majriti, Aidamir al-Jildaki, or in fact, in any other Arabic chemical writer, so that I do not believe that they can have had any considerable influence. Many of the ideas and much of the phraseology in them are of course common, but the works themselves appear to have been almost completely neglected by Muhammadan chemists. On the other hand, most of the books of Jābir which are given by Berthelot are frequently quoted by later authors, and there is no reason to doubt their authenticity; they do not, however, give an adequate picture of their author.

[11] *Op. cit.*, I, 301.
[12] It is improbable that Avicenna knew of Vergil.

In using the texts one finds at once the difficulty of referring to any particular passage, as the pages of the MSS. are not numbered, neither are any indications given in the Arabic of the corresponding pages in the translation. This would not be a drawback in the case of a work divided into numbered sections and subsections, but it is very aggravating in the long and rambling treatises chosen and causes a great waste of time. Moreover, the texts themselves cannot be said to be properly established, since they were made from single manuscripts, often imperfect. With the books of Crates and Al-Habib this was inevitable, since no other MSS. are known, but another MS. of the Ostanes is in the British Musuem, and MSS. of the "Book of Royalty" and "Little Book of Mercy" are fairly common. The "Books of Mercury" and the other books of Jābir are freely quoted by Al-Jildaki and others, and their texts could thus have been partially checked.

In the first volume of *La Chimie au Moyen Age*, Berthelot brings to bear his knowledge of mediæval Latin treatises supposed to have been translated from, or based on, Arabic originals, but, as has already been pointed out, he is here attempting to explain *ignotum per ignotius*. In the Latin works it is impossible to separate the indigenous from the foreign, whether in ideas or in facts, without a previous knowledge of the later developments of Arabic chemistry, especially in Spain; now it is of Spanish-Arabic alchemy that we know least. A work of capital importance here is the *Rutbatu'l-Hakim*, ascribed, probably falsely, to Maslama al-Majriti, who died in the early years of the eleventh century, and it is to be hoped that the task of editing, translating and annotating this valuable book will be undertaken at no distant date.

The *Liber de Septuaginta* is probably the most useful tool which Berthelot had at his disposal in this connexion, as it appears to be directly translated from the Arabic of Jābir ibn Hayyān. He deals with this in Chapter IX of Volume I, but it deserves a much fuller treatment. As an example of the superficiality of his work one may mention that, in comparing the list of titles of works of Jābir quoted in the *Liber LXX* with that given in the *Kitāb al-Fihrist*, he has overlooked the correspondence between the *Intentio Intentionum* of the former with the *Kitāb 'Ard al-'Irād* of the latter, and that between the *Albicalmon* and the *Kitāb Abi Qalamun*, the *Elementum yrci* and the *Kitāb Ustuqus al-'Uss al-Awwal*, the *Chapitre des luts* and the *Kitāb al-Tīn*, and others.[13]

We have seen therefore :—

(1) That Berthelot had no idea of the vast extent of Arabic chemical literature;
(2) That he used the bibliographical material only superficially;
(3) That even in this superficial examination he was often very inaccurate;
(4) That many of his identifications are unsupported by evidence, and that others are certainly incorrect;
(5) That he took no pains to check the dates assigned by him to various authors, even ascribing Avicenna, in one place, to the 12th century;
(6) That the texts he printed cannot be said to be properly established, since they were made from single MSS., even where other MSS. of the same works existed;
(7) That the works of "Crates" and "Al-Habib" appear to have been unknown to most of the chemists of Islam;
(8) That the works of Jābir chosen are not representative;
(9) That the absence of appropriate pagination in the texts and translation renders reference very difficult;
(10) That the annotations are few and chiefly concerned with one point only, namely, the relation between Greek and Arabic alchemy;
(11) That the use of mediæval Latin works to explain Arabic ones is very limited in its application, unless a previous knowledge of the latter has been obtained;
and (12) That the most important Latin work employed by Berthelot has received insufficient treatment.

The general impression conveyed by a study of Volumes I and III of *La Chimie au Moyen Age* is, indeed, that of a confused mass of undigested material, rendered still more confused by careless scholarship. It is not surprising, therefore, that the conclusions at which Berthelot arrived are frequently misleading and very often quite inaccurate, while many others require considerable modification. It is to an examination of these conclusions that we must now turn.

---

[13] I have not seen Berthelot's more recent edition of the Liber LXX, in *Archæologie*, 1906.

II. BERTHELOT'S CONCLUSIONS ON ARABIC CHEMISTRY

Since Berthelot arrived at conclusions of the widest extent as to the nature of chemistry in Islam, one cannot hope here to deal with the whole matter fully, or even, indeed, with more than a fraction of it. To examine it fully would be to write a complete history of Muhammadan chemistry, for Berthelot has something to say about the earliest period and the latest, in spite of the fact that he did not know what was going on in the meanwhile. I propose, therefore, to state shortly some of the principal points which Berthelot believed himself to have made, and to examine these briefly in order to arrive at some estimate of their worth. This is all the more necessary since historians of chemistry have, up to quite recently, accepted Berthelot's work as authoritative.[14]

1. " Les Arabes, en effet, n'ont pas connu les Grecs directement, mais par l'intermédiaire des Syriens, qui avaient les premiers traduit les philosophes et les savants grecs dans une langue orientale." (Vol. I, p. iv.) Comment upon this conclusion may be confined to the remark that it is an over-statement of the case, and that, as Steinschneider has abundantly shown, numerous books were directly translated from the Greek into Arabic. One may also refer to the well-authenticated tradition that Khalid ibn Yazid had many Greek alchemical treatises translated into his mother-tongue. Whilst Berthelot has conclusively shown that much alchemy passed to Islam from the Greek *via* Syriac, he has under-rated the Persian contributions, which were, perhaps, as important as those of the Greeks themselves. Additional light on this subject is being provided by the masterly researches of Prof. Ruska.

2. " L'ensemble des ouvrages arabes que nous allons publier, joints aux traités syriaques contenus dans un autre volume, présente un grand intérêt pour l'histoire de la science, attendu qu'il fournit une connaissance solide de la véritable alchimie arabe, ignorée jusqu'à ce jour." (Vol. III, p. 25.) This passage requires the most careful examination, for it makes two definite claims, namely (*a*) that Berthelot's work was the first in the field, and (*b*) that it furnishes a sound knowledge of the real alchemy of the " Arabs," or rather Arabic-writing authors. The first of these two is merely a question of priority and of no particular importance, but it is necessary to point out that Prof. Wiedemann had been working at the subject for several years before Berthelot, and had published some of his researches, which appear to have been unknown to, or neglected by, the latter. Kopp also, although handicapped—like Berthelot himself—by lack of knowledge of Arabic, had investigated Muhammadan chemistry as far as possible in the circumstances, and had consulted Orientalists on several particular points. Kopp's work is still of the greatest value, and is characterised by its accuracy. Thus, while Berthelot was certainly the first to publish texts of Arabic chemical books, the work of the two men just mentioned should not be forgotten, especially as in many respects it reaches a much higher level of scholarship than does *La Chimie au Moyen Age*.

The second claim (*b*), however, is really the crucial question of the whole discussion. In the present articles much evidence has been adduced to enable us to arrive at a considered judgment on the matter, and the inadequacy of Berthelot's work has, I hope, been made clear. Nevertheless, in order to place the matter beyond doubt it may be advisable to consider more closely the proportion which exists between the fraction of the material used by Berthelot and the total field.

The period during which chemistry flourished in Islam covers some seven hundred years—from the time of Khalid ibn Yazid (seventh century) to that of Aidamir al-Jildaki (fourteenth century). The chief centres of study were Iraq and Spain, and in that order. Jābir ibn Hayyān (eighth century) was undoubtedly the most accomplished chemist of the early period, and about 80 of his works are extant, whole or in part. The largest and most important is the *Kitab al-Khawass*, or *Book of Properties*, preserved in two MSS. in the British Museum. It will be obvious that a great deal of work will have to be done before a just estimate of Jābir's chemical knowledge can be obtained, and it will not be denied that Berthelot certainly was not in a position to make such an estimate. Several of his conclusions on this particular subject have already been proved incorrect, notably his statement that Jābir does not mention the sulphur-mercury theory of metals, nor admit " arsenic " as a third constituent of metals.

As far as our information goes, Jābir's death cannot be placed later than the reign of Al-Ma'mun (813-833 A.D.), so that it is apparent that Berthelot has entirely neglected a period of no less than five hundred years, except for the short articles he has given upon Bubacar (Rhazes) and Avicenna, based on Latin MSS. and therefore not authoritative. His claim that his researches " furnish a sound knowledge of Arabic alchemy " is therefore absurd ; even if he had modified it by adding the words " as far as it affected European alchemy," he would still have been claiming far too much, for the works of Al-Razi and Ibn Sina exercised a great influence upon the future development of the science. Moreover, since it was chiefly in the tenth and twelfth centuries in Muslim Spain that the transmission to Europe flourished, it is undeniable that a study of this period of Islamic chemistry is absolutely essential; and this Berthelot wholly neglected. The important "Letters" of the "Brethren of Purity" (tenth century A.D.), which contain a large section dealing with chemistry, and which were one of the chief sources of chemical knowledge in Moorish Spain, are not even mentioned, in spite of the fact that their plain and straightforward style and notable freedom from mysticism bear the clearest witness to the fact that it was in Islam that chemistry first became a true science.

---

[14] Even de Lacy O'Leary has implicitly relied upon him in his *Arabic Thought and Its Place in History* (1922, p. 120). It is, however, to be noted that Prof. Lynn Thorndike (*History of Magic and Experimental Science*, 1923, II, 217), whilst accusing Lippmann of belittling Berthelot " on petty pretexts," himself says " Berthelot is a poor guide in such matters (alchemical MSS. of the Middle Ages) since his pretentious volumes are based on the study of a comparatively small number of MSS. at Paris."

The numerous works of Aidamir al-Jildaki (died about 1360 A.D.), which form a sort of encyclopædia of chemistry and give one a more or less accurate picture of six hundred years of the rise and progress of the science in Islam, together with much biographical information and innumerable lengthy quotations, seem to have been quite unknown to Berthelot. Al-Jildaki had a better knowledge of the Muhammadan chemists than anyone else had possessed, and he frequently gives long extracts from books which have now disappeared; he is in fact an indispensable source for the study of "l'alchimie arabe." Fortunately, MSS. of his works are plentiful and copies may be found in all the great European libraries.

As a last source unused by Berthelot may be mentioned the large number of books on minerals and precious and semi-precious stones, which provide material of importance to both the chemist and the mineralogist. Further elaboration of this point seems unnecessary, but one may perhaps remark that, to look at the matter from a numerical standpoint, Berthelot employed less than 4 *per cent.* of the available material, dealt with only three important chemists (viz., Jābir, Al-Razi and Ibn Sina) out of, at least, two or three dozen who require study, and passed over in silence nearly half a millennium.

It is fitting that these articles, which have contained much criticism of Berthelot's work, should also draw attention to those features which are praiseworthy, and one may readily acknowledge that such features are many. Berthelot's courage in attacking a problem of so great a difficulty was amazing, and that he achieved some measure of success is not denied, even by those who have most strongly felt his deficiencies. After all, it must be remembered that the historical researches were only the product of the leisure of an extremely busy man, and as such they compel our admiration. It is a sufficient testimonial to the worth of the researches on Arabic chemistry, that every one who has worked at the subject since they were published has used them, and perhaps occasionally abused them, but has never been able to neglect them. I feel personally that their chief value lies in the stimulus they give, for no one can read them without realising that the history of the progress of chemistry in Islam is probably the most important question for the modern historian of science.

The proof of the debt which Islam owed to the Greeks, the elucidation of the great help rendered in this connexion by the Syrian translators, the publication of the *Liber LXX* and the nine works of Jābir ibn Hayyān, the translation of the passage from the *Fihrist*, the attention drawn to the important book of "Bubacar"—for all these valuable contributions to knowledge Berthelot deserves our warmest thanks. The magnitude of his services was great and should not be belittled on insignificant grounds; yet I think they were greatest not in accomplishment, but in indicating what was to be accomplished. "*Ce n'est que le premier pas qui coûte*," and this was taken for us by Berthelot.

COMPOSITION FLOORING

By RAYMOND RENARD BUTLER

The chief binding materials used in modern jointless flooring are portland cement, magnesite cement, bitumen, rubber, and hard-burnt plaster of Paris. Of these the last named is little used in this country, but finds more extensive application on the Continent under the name of Estrich gips.

The life of a jointless floor depends mainly on the ability of the binding material to resist wear and tear. From the standpoint of the chemist the influences at work upon such floors are both mechanical and chemical:—(*a*) Attack by iron tyres of trolleys, etc. (*b*) Attack of the flooring on rubber tyres. (*c*) Influence of oil. (*d*) Influence of water. (*e*) Influence of acid. (*f*) General foot traffic. The problems of fireproofing and sound-proofing are also important.

It will be convenient to deal with the subject sectionally.

PORTLAND CEMENT

Olive, whale, bone and wood oils, and tallow show a tendency to attack freshly laid concrete, but concrete one month old is immune. Mineral oils derived from the distillation of coal products are without action on the cement unless contaminated with acidic substances. Even weak acids such as vinegar, sulphurous acid and carbonic acid in large quantities have a destructive effect. Alkalis such as potash and soda have no action, but ammonium salts tend to disrupt the surface, with the liberation of small quantities of ammonia. Organic fertilisers and manures attack lean concrete (*i.e.*, concrete having a low percentage of cement) when freshly laid, but not concrete one month old.

Water is practically without action on the cement, which may be rendered impervious by such substances as bitumen or sodium silicate. Bitumen is frequently used to render cement acid-proof (see "Bituminous Materials and Cement," U.S. Bureau of Standards).

The use of sodium silicate as a top dressing will satisfactorily cure the "dusting" of Portland cement, but it should be noted that common viscous "waterglass" is not always satisfactory. Such solutions are usually cloudy and have a soda/silica ratio varying between 1 to 4 and 2 to 3. The most generally useful silicate for use on cement has a ratio Na_2O/SiO_2 of 1 to 3·3. The solution contains 3·3 mols of silica to one of soda and is usually clear. It is now possible to obtain a "neutral" silicate in the form of a white powder, soluble in hot water, and containing about 60 per cent. of silica and 20 per cent. of soda.

A report on "Service tests on Concrete Floors" has been published by the U.S. Bureau of Standards, (Oct. 1920).

MAGNESITE CEMENTS

Magnesium oxide, prepared by heating magnesite ($MgCO_3$) to 800° C., is mixed with a strong solution of magnesium chloride; and the mixture sets to a hard compact mass having the formula $5MgO.MgCl_2.XH_2O$, where X has the value of 17 approximately. The magnesia should contain between 85—90 per cent. MgO, and less than 4 per cent. CaO (lime). The specific gravity of the $MgCl_2$ solution usually lies between 28° and 30° Bé. The density of most magnesite floorings is about 1·1 (water=1). Such floors should not be washed too frequently. A preliminary dressing of linseed oil, followed by ordinary floor polish, is probably the best treatment.

BITUMEN

Bituminous substances, acid-proof and waterproof, are valuable as viscous binding materials, and are frequently mixed with finely-graded granite dust, limestone dust and cement, in order to increase the viscosity. (See D. C. Broome, *J.*, 1923 May, 192 T.) If V=the viscosity of the tar alone at any temperature between 60° F and 100° F and Vp=viscosity of the mixture at the same temperature, it is found that $Vp=V^x$, where the value of $X=kp+1$, p being the percentage of filler added and k a constant whose value is $8{\cdot}5\times10^{-3}$. The percentage p of filler added should be less than 15 per cent.

It is possible therefore to calculate with reasonable accuracy the amount of filler which must be added to a low-viscosity tar to raise the viscosity to a given value Vp, since from the equation, $Vp = V^{(Kp+1)}$ and therefore

$$p=\frac{\log\frac{Vp}{V}-1}{8{\cdot}5\times10^{-3}}.$$

The equation should not be used for tars of a consistency V of less than 10 seconds at the temperature of the experiment, and no particles larger in diameter than 0·01 inch should be added. Reference may be made to the "General Directions for Tar Treatment of Roads" (Ministry of Transport, Roads Dept., 1923).

RUBBER

Rubber is resistant to water and acid under general conditions, but is considerably affected by oil. With raw rubber at 8d. to 10d. per lb. it should be possible to put on the market a self-coloured rubber $\frac{1}{8}$ inch in thickness at 12s. per sq. yard. The present maximum width of such compositions is 48 inches. Sheet rubber can be readily trimmed with a wet knife, and joints can be fixed down on to a cement base with rubber solution, or on to wood with glue. The material is eminently suitable for hospitals and institutions where the floor surfaces are washed regularly.

CALCIUM-SULPHATE CEMENTS

Hard-burnt plaster of Paris, produced at temperatures above 400° C, sets only very slowly, but the finished product is extremely hard. Experiments made by Haddon (*cf. J.*, 1921, 122 T) show that the expansion of plaster of Paris on setting is least when accelerators such as K_2SO_4 or $FeSO_4$ are used, and greatest when retarders (*e.g.*, $CaCl_2$) are employed. The tensile strength of briquettes in which an expansion of 5 per cent. has occurred is considerably less than that of a plaster in which expansion is normal, say 0·1 per cent., and has not been influenced by retarders. It is found that mineral oils have no effect on the tensile strength. As flooring compositions, such cements have the disadvantage that they set very slowly.

MISCELLANEOUS CEMENTS

Many modern composition floors consist of mixtures of short fibre asbestos held in a binder of sodium silicate with or without the addition of other aggregates such as powdered serpentine; the colouring matter in such flooring is usually oxide of iron (rouge).

PATENT LITERATURE

One suggestion for sound-proof material (E.P. 110,194, 1916, *J.*, 1917, 1237) involves the production of a porous structure by suitable quantities of sand and Portland cement. A fireproof composition is described in E.P. No. 121,986, 1917, and an acid-proof mixture in 121,855, 1918; (*J.* 1919, 107 A.) Light concretes frequently contain cork dust or sawdust, and sometimes dilute sodium silicate is added : as examples of porous aggregates see E.P. Nos. 173,965, 1920, and 180,887, 1921.

Patent No. 13,075, 1915, describes a magnesite composition, in which magnesia is mixed with 15—25 per cent. of its weight of sawdust, and 50 per cent. of its weight of $MgCl_2$ solution (18° Bé), a facing of slagwool or asbestos being given.

A. A. Shively (*J. Ind. Eng. Chem.*, 1916, 8, 672) recommends the use of a mixture consisting of, per cent., magnesia 40, clay 20, venetian red 12, sawdust 10, terra alba 8, $MgCl_2$ 10, water being added as required ; compare also Nos. 15,038, 1914 ; 120,727, 1917 ; 162,514, 1920 (*J.*, 1921, 434 A) and 178,880, 1920. The use of various zinc oxychloride compounds has been patented, *e.g.*, No. 194,025, 1922 (*J.*, 1923, 403 A), in which the final hardened surface is formed by the action of formaldehyde on gelatin. In No. 112,196, 1917 (*J.*, 1918, 89 A) it is stated that the double oxychloride has the composition $Zn_2OCl_2.Ca_2OCl_2$.

The stability of bituminous substances is stated to be increased by the admixture of at least 2 per cent. of clay paste, the water being removed by evaporation (No. 9838, 1915). Reference may be made to a soundproof mixture covered by a German patent (329,410, 1918 ; *J.*, 1921, 220 A).

A plastic composition resembling natural asphalt is covered by No. 181,092, 1921, in which one of the constituents is rubber. The addition of 2 parts hydrated aluminium oxide to 1 part of rubber is suggested as a method of rendering rubber "non-flam" (159,014, 1919 ; *J.*, 1921, 269 A), and the same fireproofing effect is claimed for sodium tungstate in a mixture consisting of rubber solution, woody fibre, and sodium tungstate (No. 110,941, 1916). Reference may also be made to No. 107,107, 1916 (*J.*, 1917, 895), and to an American patent which claims that high fusing point and marked colloidal properties are obtained by incorporating 1—1·5 parts of rubber and 100 parts of bitumen.

Silicate floorings are represented by No. 183,753, 1921 (*J.*, 1923, 57 A), the mixture consisting of quartz 50 pts., shavings 40 pts., zinc oxide 5 pts., potassium silicate solution (30° Bé) 50 pts. In place of shavings, short fibre asbestos is frequently employed.

An acid proof composition is covered by No. 108,278, 1917 (*J.*, 1917, 965), which consists of such an admixture as quartz 90 pts., calcium phosphate 10 pts., and sodium silicate 30 pts., to be mixed in the usual way, and treated with an acid such as sulphuric acid either just before or just after it sets.

Northern Polytechnic
London, N. 7

FORTHCOMING EVENTS

Oct. 15. INSTITUTION OF RUBBER INDUSTRY, *Manchester Section*, Midland Hotel, at 7.30 p.m. "Rubber Machinery." Discussion to be opened by H. C. Young.

Oct. 16. ROYAL COLLEGE OF SCIENCE CHEMICAL SOCIETY, South Kensington, S.W. 7, at 4.45 p.m. "Water as a Catalyst," by Prof. H. B. Baker, C.B.E., M.A.

Oct. 16. THE UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.30 p.m. "The Present Tendencies and Future Compass of Physiological Science," by Prof. A. V. Hill, F.R.S.

Oct. 18. THE CHEMICAL SOCIETY. Ordinary Scientific Meeting, Burlington House, Piccadilly, W. 1. "Studies in Electrovalency. Part III. The Catalytic Activation of Molecules and the Reaction of Ethylene and Bromine," by R. G. W. Norrish.

Oct. 18. THE INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. Inaugural Address by the President, Dr. A. Russell.

Oct. 18. INSTITUTION OF MINING AND METALLURGY, Cleveland House, City Road, E.C. 1. General Meeting.

Oct. 18 to 20. INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND. Conference of Fellows and Associates with the Liverpool and N. Wales Section of the Institute in Liverpool.

Oct. 19. THE SOCIETY OF DYERS AND COLOURISTS, *Manchester Section*, 36, George Street, Manchester. "Some Aspects of the Theory of Quinones," by Prof. R. Robinson, D.Sc., F.R.S.

Oct. 19. SOCIETY OF CHEMICAL INDUSTRY, *Swansea Section*, Thomas's Café, Joint Meeting with the South Wales Section of the Institute of Chemistry, at 6.30 p.m. Discussion on "Short Cuts in Analysis."

Oct. 19. THE INSTITUTE OF METALS, Institution of Engineers and Shipbuilders, 39, Elmbank Crescent, Glasgow, at 7.30 p.m. "Large Metallic Crystals and Some of their Properties," by Prof. H. C. H. Carpenter.

Oct. 18 and 19. THE TEXTILE INSTITUTE. Annual Autumn Conference at the Exhibition of Textile Machinery, etc., in the Junior Training Halls, Leicester. "Artificial Silks." P. E. King. "The Application of Dyes to Textile Fibres and Fabrics," Prof. J. Thorpe.

Oct. 19 THE INSTITUTION OF MECHANICAL ENGINEERS. General Meeting, Storey's Gate, St. James's Park, S.W. 1., at 6 p.m. Presidential Address by Sir J. Dewrance, K.B.E.

Oct. 22 THE INSTITUTE OF PHYSICS. The Institution of Electrical Engineers, Victoria Embankment, at 5.30 p.m. "Physics in Industry," by Dr. A. E. Oxley.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS,

October 31, 1923

This Dinner is being arranged under the joint auspices of the Chemical Society, the Institute of Chemistry, and the Society of Chemical Industry, and will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Wednesday, October 31, at 7 for 7.30 p.m. The arrangements are being made by a Committee consisting of representatives of the Societies mentioned. and of one or two other Societies.

Sir William J. Pope, K.B.E., F.R.S., will take the chair. There will be some speeches and some music as well as opportunities for social intercourse.

No similar dinner for chemists has hitherto been organised on exactly the same lines, and it is expected that the gathering will be not only very pleasant, but will be useful in promoting that social acquaintance which is so valuable in connexion with prevailing ideas and hopes.

Members of any of the Societies concerned are invited to attend and bring guests. The price of tickets for ladies and gentlemen is 12s. 6d. each, not including wine. Applications for tickets (accompanied by the appropriate remittance) should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2, as soon as possible.

Applicants are invited to state names of any friends beside whom they wish to be seated, and the names of guests should be furnished at the same time.

DEATHS

Dickenson, F. M. (elected 1898), of Broken Hill Proprietary Co., 3, Great Winchester Street, London, E.C. 2. Secretary. On May 22, 1923.

Kuttroff, Fred (elected 1900), of 128, Duane Street, New York City, U.S.A. Merchant. On October 22, 1922.

Leonard, Wm. J. (elected 1884), of Lindfield Gardens, Hampstead, and Hope Chemical Works, Hackney Wick. Naphtha Distiller. On September 10, 1923.

Muspratt, Dr. Edmund K. (Original Member), of Seaforth Hall, near Liverpool. Alkali Manufacturer. On September 1, 1923.

Thomson, Wm. (Original Member), of the Royal Institution Laboratory, 79A, Princess Street, Manchester. Analytical and Consulting Chemist. (Former Chairman of the Manchester Section.) On October 4, 1923.

MANCHESTER SECTION

The first meeting of the Session was held on October 5, Dr. H. Levinstein being in the chair. The attendance numbered about 60, the president of the Society, Dr. E. F. Armstrong, F.R.S., being also present. In opening the proceedings the chairman referred to the death of Mr. William Thomson, an original member of the Society, and a member of the Committee of the Manchester Section from as far back as 1885, and the Honorary Secretary (Mr. L. Guy Radcliffe) was authorised to send a vote of condolence to the bereaved family. The chairman then read an address, entitled "Recent Progress in Chemistry."

He said that when he last addressed the Section in March he reviewed briefly the progress made in British chemical industry since 1914. The war gave the opportunity for English chemical manufacturers to supply products for which a demand had previously been created by the German "Interessengemeinschaft" ("I.G."), and which had become necessary for the conduct of our trade. Thus very large dyestuff and other factories were erected, and of their activities he had endeavoured to give some brief account.

They would not fall into the error of thinking that "Capturing the German trade" (he believed that was the correct catch-phrase) was quite so simple a matter as merely making in England things previously made in Germany. It was not always easy to copy a German dyestuff merely from a specification, but in the technology of the dyestuff and fine chemical industry one did not expect it to be. It was certainly necessary to do this so that you could supply the products which the consumers had been accustomed to get from Germany, but this was just ordinary business routine in a dyestuff factory. Consider the life history of such a substance. Discovered in a German dyestuff laboratory, it was picked out by a discerning German technologist as a likely commercial "winner," made on a large scale probably in existing plant, until a demand had been created for it by a German technical sales organisation satisfied of its merit and determined to make it a commercial success. We should have a false sense of values if we considered that we were catching up merely by copying German patents, and he regretted the publicity which was sometimes given to this aspect of the question. Surely no-one present would think it possible to battle successfully in the world's markets by copying other people's products after they had been proved commercially successful by enterprising competitors. Everybody knew that the dye industry was not static, but progressive. Frequently it was stated that we in this country were forty years behind the Germans in chemistry. This view was erroneous. In some branches of chemical science we led the world, and in none could we be said to lag conspicuously behind any other nation.

The British Chemical Industry would be very well represented at the British Empire Exhibition at Wembley, to be opened in April, 1924. The Industrial Exhibit would be a collective exhibit in the sense that every exhibit would form part of a homogeneous scheme. There would also be an exhibition of British Chemical Science, which would be placed close to the industrial section, and would add greatly to its value. This scientific exhibit was being organised by a thoroughly representative committee, including representatives of the Royal Society, the Chemical Society, the Institute of Chemistry, the Society of Dyers and Colourists, the Institute of Petroleum Technologists, the Society of Chemical Industry, and the Association of British Chemical Manufacturers and also of the Federal Council of Pure and Applied Chemistry. Further, it had the great advantage of being in consultation with, and represented on, the British Empire Exhibition Committee of the Royal Society.

Dr. Levinstein then dealt generally with the progress of chemical science since the time of John Dalton, mentioning the names of numerous British investigators and stating the results achieved by them. In conclusion, he said it was desirable that the intimate bearing of biochemistry on many of the circumstances of daily life should find an appropriate expression at the forthcoming British Empire Exhibition. The Scientific Sub-Committee of the Chemical Section had appointed a Biochemical Sub-Committee, comprising Messrs. J. L. Baker, Dudley, A. Harden, T. A. Henry, Gowland Hopkins and Schryver, and it had been suggested that the exhibits should be arranged under the groups: (1) Vitamins; (2) Insulin; (3) Standardisation of animal extracts; (4) Fermentation, including alcohol, acetone, glycerol, lactic and butyric acids, beer and cider; (5) Bread; (6) Tannins and leather; (7) Nutrition and protein decomposition; (8) Cotton; (9) Silk; (10) Sewage and water; (11) Respiration of plants and animals; (12) Plant constituents; (13) Therapeutics, ergot, digitalis, squill, etc.; (14) Glue and gelatin; (15) Photographic exhibit of English biochemical laboratories.

One or two investigators whose names were prominently associated with the respective groupings would be invited to make detailed suggestions as to the nature of the exhibits. Thus Profs. Harden and Drummond might deal with vitamins, Dr. Dudley with insulin and animal extracts, Dr. Henry with plant constituents, Prof. Schryver with glue and gelatin, etc. Prof. Gowland Hopkins would deal with muscle work, lactic acid, Bence Jones protein, accessory food factors, uric acid and its derivatives on butterflies' wings, tryptophan, etc. Other exhibits might be:—Structure of the atom, Sir Ernest Rutherford, F.R.S., spectroscopy, Sir Herbert Jackson, F.R.S., crystallography and molecular structure, Sir Henry Miers, F.R.S., valency and theories of chemical combination, Prof. Lapworth, F.R.S., photography, Dr. T. Slater Price, general physical chemistry, Prof. Donnan, F.R.S.

Dr. E. F. Armstrong proposed, and Dr. E. Ardern seconded, a vote of thanks to Dr. Levinstein for his address.

BRISTOL SECTION

The opening meeting was held in the University, Woodland Road, on October 4, when Mr. John F. Reid gave a paper entitled "An Outline of Rubber Manufacture," to an appreciative audience numbering 63. Mr. W. Jones was in the chair.

The author first described the coagulation of rubber latex and said that, with the exception of crêpe sole, the rubber thus obtained required further treatment. Various materials, usually fluids or fine powders, were added to produce hardness, change the colour, make manipulation in manufacture easier, and give lasting qualities, resistance to chemical action, and so forth. Of all these materials sulphur was the most important, as it caused a profound change when the mixture was vulcanised, or "cured." The raw rubber was made plastic by grinding between steam-heated steel rolls, one of which revolved faster than the other. After about half-an-hour the powders were slowly added to the churning mass, the sulphur being added last. The material might be made into sheets by running it through hot calenders, or might go direct to extruding or forcing machines. The chief varieties of forced rubber were gas-tubing, carriages and pram tyre, linings for hose and window glazing strip. These were vulcanised in a bed of French chalk for from anything between 30 minutes to 4 or 5 hours at temperatures between 260° and 300° F., obtained by steam pressure. Calendered rubber varied in thickness from 0·01 in. to about 0·1 in., and articles of any thickness could be built up by adding the required number of layers, which could then be cut approximately to shape and vulcanised in a steel mould, under hydraulic pressure. Rubber was not moulded like lead or steel, as open heating destroyed it. The most recent invention, however, employed a solution of rubber which was poured into a mould, the rubber rendered vulcanisable and the solvent dried off. The most outstanding physical property of finished rubber was its elasticity; it stretched under stress up to 900 per cent. or more of its original length before it broke. Its specific gravity varied from about 0·9 to 4·8; and it might possess any colour. Its tensile strength was surprising, specimens occasionally reaching a strength of 6000 lb. per sq. in. It was a non-conductor of heat and electricity, and could be obtained in a state which resists abrasive wear to a very marked degree. It could be made highly resistant to the action of dilate acids and alkalis, but was readily attacked by concentrated mineral acids.

An excellent discussion ensued, and the proceedings terminated with a vote of thanks to the lecturer.

It has been arranged for the members to visit the Melksham works of the Avon Rubber Co. on October 18.

CHEMICAL SOCIETY

The first ordinary meeting after the vacation was held on Thursday, October 4, 1923, at 8 p.m., the President, Prof. W. P. Wynne, F.R.S., occupying the Chair.

The President referred to the death of Prof. Herbert McLeod, F.R.S., paying a tribute to the eminent services he had rendered to the cause of Science, and in particular to the Chemical Society, both as a member of the Council and as a Vice-President.

Since the last meeting of the Society, new arrangements had been made regarding the *Journal*, which, as from January next, would be dissociated from the Abstracts, the two sections being issued separately. Abstracts of papers appearing in the *Journal* would, however, be included in future in the volume of Abstracts. Moreover, members who so desired would now be supplied in advance with *précis* of papers to be read before the Society.

Attention was also drawn by the President to the new arrangements, which materialise in January next, for the publication of the *Journal of Physical Chemistry*, under the joint auspices of the Chemical Society, the Faraday Society, and the American Chemical Society.

The following paper was read by Mr. E. C. Craven :—

Note on aqueous formaldehyde solution. W. R. Ormandy and E. C. Craven.

THE discrepancies in the published values for the densities of aqueous formaldehyde solutions probably arise from the presence of methyl alcohol. The densities of solutions prepared by refluxing with water are now found to agree excellently with the results of Auerbach and Barschall, who prepared solutions by volatilising paraform in a current of nitrogen and absorbing the gaseous formaldehyde in water. The density and the refractive index of a formaldehyde solution appear to be linear functions of the formaldehyde concentrations. Thus at 15° C.:

$d = \cdot 9992 + \cdot 00307\,C.$

$n_0 = 1\cdot 3334 + \cdot 001145\,C.$

where C = % weight of formaldehyde in solution.

The specific refractivity of the formaldehyde in the dilute aqueous solution appears to be ·205, which agrees well with the assumption that methylene glycol is formed and this assumption is also borne out by the density measurements.

Dr. W. R. Ormandy humorously suggested that since formaldehyde evidently did not exist as such in its aqueous solution, the problem whether or not it is a "synthetic organic chemical" would appear to admit of easy solution.

Dr. H. J. S. Sand read a paper entitled

The interaction of potassium tetroxide with ice, and with dilute sulphuric acid. H. Hawley and H. J. S. Sand.

EXPERIMENTS were carried out to determine whether any evidence could be found for the formation of an oxide of hydrogen higher than the dioxide when ice or dilute sulphuric acid is brought together with potassium tetroxide at or below 0°. For this purpose the oxygen evolved on bringing the reactants together was measured, and found to be slightly greater than that which would have quantitatively left a derivative of hydrogen dioxide in solution. The solutions remaining were also tested as regards their velocity of reaction with hydrogen iodide and found to agree accurately with corresponding ones made up from hydrogen dioxide. It is thus proved that only hydrogen dioxide results from the interaction of potassium tetroxide with ice or with dilute sulphuric acid.

Dr. Irvine Masson remarked that the authors' results appeared to be conclusive, and enquired whether any ozone was present in the evolved oxygen.

Dr. T. Slater Price said that by avoiding the use of permanganate the authors had eliminated uncertainty due to the possible formation of persulphuric acid; he suggested the use of colloidal platinum in identifying the product of the reaction by means of velocity-experiments.

In reply, Dr. Sand said that ozone had not been noticed in the oxygen; he had not used colloidal platinum, but was under the impression that its use would involve greater difficulty in reproducing the experimental conditions.

Mr. R. G. W. Norrish gave an account of experiments on

The direct union of oxygen and sulphur (being Part IV. of "The conditions of reaction of hydrogen and sulphur"). R. G. W. Norrish and E. K. Rideal.

THE reaction of oxygen and sulphur has been studied by a dynamic flow method, between the temperatures 235° and 385°. Below 305° it proceeds with a temperature coefficient of 1·63; above 305° this falls off rapidly, due to the secondary formation of sulphur trioxide. The reaction is limited to the surface of the sulphur and the walls of the vessel, and proceeds equally well on both, pointing to a liquid film covering the whole surface of the vessel. This film can be seen under certain conditions by the development of interference colours. The rate of reaction is proportional to the pressure of oxygen, but at 0·41 atm. pressure a break occurs in the pressure-velocity curves, indicating that the reaction on the surface is complex and is made up of the sum of two reactions, one of which—the A reaction—becomes independent of pressures above 0·41 atm., while the other—the B reaction—remains proportional to the oxygen pressure as high as at least 1 atm. The temperature coefficients are respectively, 1·48 and 1·77, and the critical increments 25,750 cals. and 37,450 cals. The figures for the A reaction fulfil a prediction of the hypothesis advanced in earlier papers of this series. In explanation of the facts the assumption is made that the sulphur surface contains two different kinds of sulphur molecules, with which the oxygen molecules striking the surface react differently, giving the A and B reactions. The fact that the A reaction finally becomes independent of pressure indicates that the rate of production of the second allotropic form of sulphur now limits the velocity of the reaction. The temperature coefficient of the interconversion of the two forms of sulphur is shown to be 1·48 as required by the hypothesis advanced. A table of seven different reactions of sulphur is given which shows that their critical increments are simple multiples of a constant quantity, which is considered to be the half value of the work required to create one free sulphur bond.

Dr. J. J. Fox said that whilst some S_2 was undoubtedly present, most of the sulphur vapour consisted of S_8 molecules, with which the oxygen reacted. It was necessary, therefore, to take into account the heat change involved in the reaction $S_8 = 4\,S_2$.

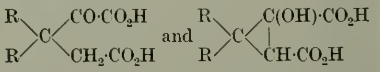
Mr. S. Sugden enquired whether the formation of sulphur trioxide above 305° appeared to be connected with the glowing of sulphur just below the boiling-point.

Mr. Norrish agreed that S_8 was present, but together with S_4, S_2, and S; the velocity of reaction, and likewise the temperature coefficient, were, however, determined by the slowest reaction, namely, $S_2 \rightarrow 2S$. He had observed that a glow generally preceded an explosion of the mixture of sulphur vapour and oxygen when the temperature was raised and the pressure increased. It was certain that no sulphur trioxide was formed at the lower temperatures employed.

Prof. J. F. Thorpe, F.R.S., described the following investigations :—

Ring-chain tautomerism. Part VII. The effect of the cyclohexane nucleus on the carbon tetrahedral angle. E. W. Lanfear and J. F. Thorpe.

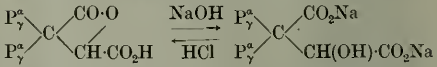
THE final proof that the directions of two valencies of a carbon atom are profoundly altered by the volumes of the groups attached to the two other valencies, or by the inclusion of these other valencies in a ring complex having known carbon to carbon angles is now supplied. Hitherto it has been shown that two substances



are tautomeric in strong potash solution when R, R = diethyl or di-*n*-propyl, but that when R, R = 2 hydrogen, 2 methyl, cyclopentane, or methyl ethyl, the keto-form is alone stable. Similarly, it has been shown that when R, R is a cyclohexane complex the hydroxy-ring form is alone stable. It is now proved that in the di-hydrogen, dimethyl, cyclopentane and methyl ethyl series the hydroxy-ring form is unstable, and that in the cyclohexane series the keto-form is unstable.

The formation of stable β-lactones. L. Bains and J. F. Thorpe.

HITHERTO the β-lactones which have been prepared have been found to be unstable to alkali; that is to say, they do not, under this treatment, behave like the γ-lactones and yield alkali salts of the hydroxy-acids from which the lactones can be regenerated. The alteration of the carbon tetrahedral angle by the di-*n*-propyl group causes, however, the four-membered heterocyclic nucleus to be so readily formed that the β-lactone behaves like a γ-lactone :—



The President remarked how fruitful had been the idea of the carbon tetrahedral angle in the hands of Prof. Thorpe, whom he thanked for speaking at very short notice.

ACADÉMIE DES SCIENCES

During the meeting held on September 17, Dr. Roux communicated a paper by Monsieur J. Regnier on "The measurement of the degree of anæsthesia produced by local anæsthetics," which indicated that novocaine was ten times less active than cocaine, and that stovaine, with an activity almost equal to that of cocaine, had a much less lasting action.

On October 1. Monsieur Molliard communicated a paper by M. Préaniniznikor, explaining that the inferiority of ammoniacal salts compared with nitrates as nitrogenous fertilisers, is due to the acid secretion that they induce in the plant. If this secondary effect is eliminated, ammonium compounds give a higher yield than nitrates, but it is still true that the larger the quantity of nitrate present the better the plants develop. In a second paper the author showed that the nature of the radiations selected by the plant for photochlorophyll assimilation depend on the species of the plant. Prof. Le Chatelier described a method, based on alterations in surface tension, for the estimation of very small quantities of alkali. Monsieur Hadamard criticised Helmholtz's explanation of several paradoxes of hydrostatics. claiming that the formation of discontinuous surfaces postulated by Helmholtz to explain the slipping of a mass on a liquid layer was incomprehensible. Recent experiments by Caemichel suggested that instead of discontinuous surfaces, vortices were formed, a view that was confirmed by Prof. Volterra. Monsieur Lumière communicated a note by Monsieur le Clerc, on an error in the interpretation of the point of view in photographic reproductions.

SOCIETY OF PUBLIC ANALYSTS

Four papers were read at the meeting held in Burlington House on October 3, with Mr. P. A. Ellis Richards in the chair :—

(1) "The Sampling of Coal; the General Problem and some Experiments," by J. H. Coste, F.I.C., E. R. Andrews, F.I.C., W. E. F. Powney, F.I.C. Attention is drawn to the difficulties encountered in sampling coal, which is often a heterogeneous mixture, so that the variations in composition of different "patches" are extremely wide. These variations are likely to be more extreme where the bulk is large and where it is impossible to sample throughout the dump. General considerations that should govern the sampling are suggested, and stress is laid upon the point that if, as often happens, different workers obtain different results from samples taken from the same bulk, the discrepancies are not due to mistakes in working, but indicate the variability in composition of the coal. Experiments are described in which it is shown (1) how difficult it is to obtain a homogeneous set of samples from so small a quantity of coal as 70-80 lb., and (2) the variation in composition of samples taken progressively from a bulk of about 400 lb.

(2) "New Test for Distinguishing Castor Oil from other Oils and Determining its Purity," by H. B. Stocks, F.I.C. The test is based on the following facts :—Ordinary soap solutions are alkaline to phenolphthalein. On titration with standard acid solution a point is reached at which a state of equilibrium exists and the pink colour disappears. The amount of acid required increases with the dilution up to about 1 part in 150 or higher, at which point it becomes practically constant. With soaps of oleic, palmitic, and stearic acids, and soaps from oils composed of these acids, the figures are equivalent to approximately half the total combined alkali. With castor oil soap it is only 3 to 11 per cent. of the total. Five grams of the oil to be examined are saponified with alcoholic potassium hydroxide, neutralised, evaporated to remove alcohol, made up to 100 c.c., 10 c.c. being diluted with 250 c.c. of neutral distilled water and titrated with hydrochloric acid in presence of phenolphthalein. Castor oil gave figures varying between 4·8 and 7·9, and figures are given in the paper for a number of fats and oils and rosin, in each case very much higher than for castor oil.

(3) "The Volumetric Estimation of Vanadium in Steel," by A. T. Etheridge, B.Sc., F.I.C., M.B.E. The estimation is carried out in the same solution in which chromium has already been estimated by treating the aqueous solution of the sulphates of the metals with permanganate, filtering, removing any colour due to iron, treating with standard ferrous-sulphate solution and titrating with permanganate. This gives the chromium figure. The solution is then adjusted so that it contains about 10 per cent. by volume of sulphuric acid, excess of ferrous sulphate is added, and the solution titrated with potassium bichromate, using as indicator 5 c.c. of diphenylcarbazide prepared by dissolving 0·5 g. in 1·2 c.c. glacial acetic acid, diluting to 500 c.c., and adding to each 5 c.c. 3 drops of 25 per cent. sulphuric acid and 1 drop of potassium-bichromate solution, resulting in the formation of a deep purple colour. About half the indicator should be added within 1 or 2 c.c. of the end of the titration, and the titration continued until the purple colour has practically disappeared. The remainder of the indicator solution is then added and the end point occurs within 1 or 2 drops, an apple-green tint being formed. A small amount of ferrous solution must be present when the indicator is added, the presence of 10 per cent. of sulphuric acid is necessary, and nitric acid, other than traces, should not be present.

(4) "The Iodimetric Determination of Sugars," by C. L. Hinton, F.I.C., and T. Macara, F.I.C. The aldoses, *e.g.*, dextrose and lactose, are quantitatively converted to the corresponding monobasic acids by iodine in alkaline solution at ordinary temperature, provided the proportions of alkali and iodine to sugar are suitably controlled. The slight oxidation of sucrose and levulose found by other observers is confirmed, the extent of this action depending considerably on time and temperature of reaction as well as on the proportions of iodine and alkali used. Using standard conditions, it is possible to determine sucrose accurately in mixtures by titration before and after inversion, but the determination of other sugars is liable to be affected by non-sugar reducing substances. The method is so convenient, however, that it recommends itself technically for approximate determination of invert sugar.

PERSONALIA

The "Medaille d'honneur de l'enseignement technique français" was recently presented to Mr. Stubbs, president of the Institute of British Foundrymen, by M. Vidal, under-secretary of State.

The following promotions have been made in the Legion of Honour on the occasion of the centenary of Pasteur: Messieurs Lacroix, A. Lumière to Commanders; Messieurs Cavalier, Hadamard, Radais, Blaise, Delépine, Lespian, Muller, Denigès, Guntz, Chavanne, Kayser, de Chardonnet, Simon, Le Bel and Victor Deschiens, to Officers; Messieurs Auger, Guerbet, Guérin, Tiffeneau, Maris, Marquis, Gault, Gedechot, Rivals, Jumelle, Bourion, Darmois, Mailhe, Nicloux, Wahl, Arsandaux, Abbé Senderens, to Chevaliers; Monsieur Vallée to Commander; and Messieurs A. Latapie and C. Levaditi, have been appointed Chevaliers.

Mr. A. A. Ramsay has been appointed chemist to the New South Wales department of agriculture, in succession to Mr. F. B. Guthrie.

CORRESPONDENCE

THE GOVERNMENT LABORATORY

Sir,—With reference to your editorial remarks about the Government Laboratory, some account (illustrated) of this Laboratory is given in Sir William Tilden's "Chemical Discovery and Invention," p. 60.—I am, Sir, etc.,

St. Helens, Lancs
October 6, 1923
A. Haywood

THE CHEMICAL ENGINEER

Sir,—Mr. Gray's article on "The Chemist and Industry" (*Chemistry and Industry*, October 6) raises again, *inter alia*, that age-old controversy about the chemical engineer, with the equally old axiom that "a man cannot be both a good chemist and a good engineer." You know the tale, "Chemistry is a science, Engineering is an art," and so on. The subject has been discussed till it is threadbare, with, I contend, one great omission.

Two important books have appeared recently. One is "A Handbook of Chemical Engineering," by D. M. Liddell; the other, "Principles of Chemical Engineering," by Walker, Lewis and McAdams. Both are likely to play a part in the development of the subject, and so I will draw an inference from them. The former is a practical book, containing a good deal of theory; the latter is a theoretical book, containing a good deal of practical matter. In neither book is there much chemistry. In both books there is a whole mass of *physics*. Flow of heat, flow of fluids, handling of solids, liquids, and gases, flotation, evaporation, gas-scrubbing—are these chemistry? Yet these are the domain of the chemical engineer. Even combustion belongs to physical chemistry. It is true that the chemical engineer must know some chemistry; the potter must know how to mix his clay. But I suggest that the name is a misnomer. His principal tools are *physics* and engineering, and he should be called a physical engineer. Whilst the man is exceptional who can be both a good chemist and a good engineer, I believe that there are plenty who are both good physicists and good engineers, and these are they who are called chemical engineers. Much of the argumentation on the subject arises from a failure to appreciate this point.

These remarks do not, of course, alter the fact that there are many self-styled chemical engineers who are nothing of the sort. That is another subject.—I am, Sir, etc.,

G. J. Greenfield

Templeton Coke Works,
Consett
Oct. 8, 1923

Sir,—I was extremely interested in Mr. H. H. Gray's article "The Chemist and Industry" in last week's issue of the Journal. I am sure he is to be complimented upon his literary abilities, but I do not find myself favourably impressed by his reference to the professional "Chemical Engineer." Mr. Gray would almost give us to understand that the "Chemical Engineer" cannot exist. "Some people," he says, "profess to believe that in one and the same person an engineer and a chemist can be found." Surely the inventors of some of the wonderful chemical plants which are at present on the market have a claim to the title, also I should be inclined to suggest that engineers who have specialised in the study of machinery and plant particularly adaptable to special chemical processes have the same claim. My opinion is that Mr. Gray's ideal solution of the problem, namely, that the directing intelligence of chemical concerns should be of a chemical nature and that the executive authority—the process of doing—should be vested in the engineer, is not a solution at all, and this is evidently the opinion of others, having regard to some appointments with which I am familiar. Something more is expected to-day of the one invested with these powers; a trained business mind is wanted in all matters of administration in addition to chemistry and engineering, the knowledge and power not only to advise his firm upon the purely chemical side of the business and his ability to give sound counsel as to the most suitable plant to employ for a specific purpose, but to be able to advise his firm accurately as to initial outlays, working costs (having regard to the important question of labour), the supplies of raw or crude materials, fuel, etc., their transit and handling, and possibly the selling markets of the manufactured product and estimated yields of profit. In my opinion, the controlling influence of a chemical firm must of necessity be the combined knowledge of a chemist, engineer, and business administrator, the last being the predominating qualification.—I am, Sir, etc.,

Rugely, Stafford
October 8, 1923

TRADE INTELLIGENCE

Sir,—Being a member of the Society of Chemical Industry I have *Chemistry & Industry* posted to me weekly. There are two points upon which I desire to write to you.

First, are there ever any inquiries from overseas for such products as flour, feeding stuffs, etc., and if so, could you insert them in the paper under the weekly column "Openings for British Trade"? I notice in this week's issue an inquiry for fertilisers from Poland and think that it would be of use to those members who are interested in the manufacture of flour, foods and feeding stuffs if inquiries for these products could also be published.

The second point is—Could you publish weekly under your "Market Report" the prices of lubricating oils of standard quality, say the Anglo-American Oil Co.'s ·885 spindle oil, 900/7, Bayonne, and cylinder oils? This, I think, would be a guide to a large number of members of the Society who would be users of lubricating oils.

I make these two suggestions which perhaps you may consider would increase the usefulness of the paper to members.—I am, Sir, etc.,

N. Paice
Assoc. M.C.T.

Grimsby,

NEWS AND NOTES

FRANCE

First International Congress of Foundrymen

This Congress was held in Paris from September 12 to 15, contemporaneously with an exhibition. Amongst the papers presented were several by Messrs. Holmes, Adamson and Mayhey, who formed part of the British delegation. The paper by Mr. Mayhey on magnesium in foundry-work showed that the casting of magnesium alloys presented no great difficulties, provided that the metal was of suitable quality and that, apart from certain details of manipulation, standard foundry practice was followed. Mr. Adamson (Sheffield) spoke on the graphitisation of cast iron, M. Brizon suggested methods of avoiding the chief difficulties met in casting aluminium bronze, and the importance of the dilatometric method of investigating castings was dealt with by MM. Chevenard and Portevin. In conclusion the congress passed resolutions relating to the execution of mechanical tests on cast iron and decided to set up a mixed commission to establish methods of performing such tests.

Fuel

The total output of coal and lignite in France was 3,214,814 metric tons in July, against 3,325,778 t. in June. Imports were 2,472,728 t. including 1,624,867 t. from Great Britain, and exports totalled 177,071 t. The output of coke from the French coal mines in June was 178,427 t., imports were 301,998 t. and exports 4296 t. Production of compressed fuels reached 245,698 t.; 72,009 t. was imported and 13,349 t. exported.

Metallurgy

During the first seven months of 1923 France imported 40,214 t. of cast iron, 3817 t. of ferro alloys, 291,830 t. of iron and steel; altogether 318,012 t. of cast iron was exported. The output of iron ore reached 1,833,121 t. in July, a decrease of over 50,000 t. compared with June. The present stocks at the mines total 4,635,273 t.

It is reported that a large works is being opened at Beaumont le Roger (Eure) to work up large deposits of slag dating from Roman times. The slag is said to contain 60 per cent. of iron and nearly 20 per cent. of silica.

Potash and Salt

During July the French potash mines yielded 68,969 t. of potassium salts, equivalent to 16,876 t. of K_2O. Production of salt was 93,237 t. in the same month.

CANADA

Mineral Production, 1922

According to the Dominion Bureau of Statistics, the Canadian production and value of certain minerals and allied products in 1922 was as follows:—Asbestos, 158,023 tons ($5,552,723); iron ore, 17,971 short tons ($56,993); lead, 93,307,171 lb. ($5,817,702); silver, 18,581,439 fine oz. ($12,576,758); zinc, 56,290,000 lb. ($3,217,536). All show an increase compared with 1921 except iron ore.

UNITED STATES

A New Remedy for Diabetes

Diabetic patients cannot utilise starches and sugars, and can digest fats only partially, the objectionable acids, butyric, oxybutyric and acetoacetic acids, which contain 4 carbon atoms, being produced. These acids cause acidosis, which decreases the elimination of carbon dioxide and may result in death. Using as a basis Knoop's theory, that, in digestion, after the glycerin is split off from the fat the acid itself is oxidised by the removal of 2 carbon atoms at each step, Dr. M. Kahn argued that if, instead of a fat not containing an even number of carbon atoms (*e.g.*, $C_{18}H_{36}O_2$), one containing an odd number (*e.g.*, $C_{17}H_{34}O_2$) were used, digestion should not result in the production of an acid possessing 4 carbon atoms—*i.e.*, the objectionable acetoacetic acid. Trials with synthetic fats containing odd numbers of carbon atoms confirmed the theory, as the patients promptly lost the acidosis and improved in general health. The fat thus synthesised is glyceryl margarate $(C_{16}H_{33}COO)_3C_3H_5$, and unlike *all* fatty acids in natural fats contains an odd number of carbon atoms. It is known as "intarvin" (*i.e.*, "intermediate fat") and, according to *Industrial and Engineering Chemistry*, is now produced commercially at about $4 for 7 ounces.

GENERAL

Coal and Iron in Northern Ireland

During the past fifty years, many attempts to investigate the mineral resources of Northern Ireland, especially in regard to coal, have failed. A seam of coal, 32 feet thick, has, however, been discovered near Coalisland (Co. Tyrone), and it is hoped that production will be on a commercial basis by the beginning of February next. Two shafts have been sunk to a depth of 1080 ft., and twelve seams of coal located, ten of which are 3 ft. 6 in., and the others 1 ft. deep. It is estimated that the prospected area contains 4,000,000 tons of coal, so that assuming an annual output of 100,000 t., the mine should last forty years. It is proposed to sink a third shaft as soon as the first two are in full working order and raise the output to 3000 t. These will be the first local sales of coal, and with increased output, the selling area will be extended until it reaches Belfast, where the Corporation Gas Works alone uses 50,000 t. annually of a variety similar to the product of the Tyrone mine. Belfast imports about 1,250,000 t. of coal each year, but Coalisland is only thirty-five miles from the city and there are both rail and water facilities for the transport of the mineral.

The Antrim Iron Ore Co. of Northern Ireland operates half a dozen mines over an area of about sixty-five square miles, and produces about 60,000 t. per annum. The ore is being brought by rail to Belfast from around Glenravel, Parkmore and Broughshane, a distance of about forty miles, and is then shipped by the company's own vessels to ports on the east and west coasts of England and Scotland. The Antrim ore gives an average analysis of about 40 to 42 per cent. metallic iron, and possesses special binding qualities, which renders it of exceptional value in the manufacture of raw metal.—(*Ch. Comm. J., Sept.* 28, 1923.)

REPORTS

Fifty-ninth Annual Report on Alkali, etc., Works. *By the Chief Inspectors. Pp.* 38. *H.M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

The report on works in England and Wales states that although some sections of the heavy chemical trade show distinct improvement, conditions are not yet normal, but the introduction of new methods of manufacture is a hopeful sign. Complaints regarding registered works were few and these were promptly attended to: several works, however, had not been registered. (For technical details see *J.*, 1923, 885 A.)

Salt-cake is still made in quantity and the synthetic manufacture of hydrochloric acid promises to extend; the demand for hydrochloric acid was reduced by slackness in the fibre-separation trade. The chief feature in sulphuric-acid manufacture is the rapid increase in the use of sulphur. In ammonium sulphate and gas-liquor works the tendency is to produce neutral sulphate; haphazard methods are stated to prevail in many works that make ammonium sulphate and the whole treatment of ammoniacal liquor requires more attention. Consumers of chlorine are increasing as the old methods of making chlorine on the spot have been abolished, owing to the production of liquid chlorine.

Operations in Scotland continued to be restricted, but during later months there was increased activity in some branches. No salt was converted into alkali, and the production of salt-cake decreased, but a greater quantity of spent oxide was burned in sulphuric acid works. In some works it was thought advantageous to run gas liquor to waste rather than recover the content of ammonia.

Report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1923. *Pp.* 141. *H.M. Stationery Office,* 1923. *Cmd.* 1937. *Price* 4*s.*

The total expenditure of the Department of Scientific and Industrial Research during 1922-23 was £497,549, made up of £264,493 from the Exchequer, £48,103 from interest on the Million Fund, £95,345 from the capital of the Fund and £89,608 from fees for work for outside bodies. The chief items of the expenditure were: The National Physical Laboratory £164,906 (£90,358 received in fees should be deducted); Fuel Research Board £40,695; Geological Survey and Museum £55,935; Building Research Board £6975; Food Investigation Board £17,299; Forest Products Board £2876; grants to research associations £95,345; grants in aid of scientific investigations by other bodies £6244; grants to 304 students and research workers £50,000. Owing to restrictions in the programme of research work and to the automatic fall in wages, the net estimates for 1923-24 have been reduced to £276,863, compared with £297,437 in 1922-23.

Only one new research association for the flour-milling industry—has been established since 1921, but the formation of associations for research on adhesives, liquid fuels, pottery, paint, preserved foods, paper, china clay, mining and drugs has been discussed. It is gratifying to note that a grant is offered (*cf. Chem. and Ind.*, p. 782) to the British Photographic Research Association for a further period of four years.

The Fuel Research Board has begun work on low-temperature carbonisation, investigated the efficiency of water-gas plant, and carried out work on the combustion of coke, carbon-dioxide recorders, the Thomas calorimeter, on a tetralin-petrol mixture as motor fuel, and the carbonisation of peat. Other problems receiving attention are those of domestic heating, power alcohol, and the fermentation of cellulosic materials. Reports have been published on carbonisation in vertical retorts, water-gas plant, the air-drying of peat, an apparatus for measuring the specific gravity of gases in small quantities and the analysis of coal. Progress is being made with the physical and chemical survey of the national coal resources.

Researches ranging from investigations on alloys, illumination, radium, standard steel samples, to metrology, electric cables, lubrication, reinforced concrete, road surfaces, are in progress at the National Physical Laboratory; of great interest to chemists are the valuable researches on alloys.

The Low-Temperature Research Station at Cambridge is now at work under the Food Investigation Board and 35 research workers have now made use of it. Amongst work done under the auspices of the Board mention may be made of the isolation of pure hæmoglobin, the storage of fruit and fish, the production of succinic acid in meat during storage, and work on insulating materials, the chemistry of fats, and the chemistry of canned fish. Progress has been made in the investigations of the Forests' Products Research Board on the relations of water to wood and on the testing and preservation of timber. Under the Building Research Board, fundamental researches have been initiated on the setting and hardening of cements, the decay and preservation of stone, paint technology, and a wide series of problems of practical importance is being attacked.

Investigations on behalf of the Chemistry Co-ordinating Research Board were continued at the Royal Naval Cordite Factory on the oxidation of hydrocarbons to produce formaldehyde (*cf. J.*, 1922, 41., 303 T, 331 T, 42, 81 T, 260 T), and at the Research Department, Woolwich Arsenal, on the catalytic production of formaldehyde by the interaction of hydrogen and carbon monoxide. Other experiments related to a substitute for formaldehyde, the chlorination of methane, luminous radium compounds, the Oppau explosion (*cf. J.*, 1922, 10 R, 451 R), "permitted" explosives for coal mines, accumulators, and the corrosion of aluminium and its alloys. Metals have largely occupied the attention of the Engineering Co-ordinating Research Board, particularly in respect of "fatigue," electro-deposition and light alloys. The deterioration and strength of fabrics have been investigated under the Fabrics Co-ordinating Committee, and the Adhesives Research Committee has continued to work on glue and gelatin. Mention may be made of investigations, by other Committees, on the commercial handling of liquid oxygen and liquid air, gas cylinders, liquefiable gases, lubrication and current meters, amongst the many activities under the ægis of the Department.

During the past year, Sir G. Beilby, F.R.S., has resigned from the directorship of Fuel Research, but remains on the Advisory Council. It is pointed out that the Million Fund has now largely been hypothecated, so that it will be necessary for proposals to be begun at any early date for the formation of any more research associations. In the appendices to the report, an account is given of the new organisation for State research in France.

REPORT ON THE INDUSTRIES AND COMMERCE OF SPAIN, MARCH, 1923. *By* CAPT. M. DE B. CHARLES, *H.M. Commercial Secretary, Madrid. Pp.* 60. *Department of Overseas Trade. H.M. Stationery Office,* 1923. *Price* 2*s.*

The financial position of Spain in 1922 showed very little change compared with the previous year (*cf. J.*, 1922, 203 R.). New customs tariffs were introduced, and a commercial treaty was entered into with Great Britain; agreements were also made with France, Switzerland and Norway. Trade declined during the first half of the year, largely owing to commercial strife with France, though the position improved after the two countries had come to an agreement.

The year brought little improvement to the mining and metallurgical industries. In the coal industry the tendency to eliminate the small mines is more marked owing to their lack of capital for development. Several installations of British plant have been made for the extraction of fine coal, which forms a large proportion of the output of some mines. Though many mines closed in 1921 the output of the remainder, 2,993,099 tons, showed an increase on the total for 1920. Exports of iron ore in 1922 from Bilbao, 1,040,264 t., were more than double those of 1921, but much ore was disposed of at a loss to decrease stocks and keep the mines working. In the first nine months of 1922 1,419,255 t. of copper pyrites were exported (961,334 t. in the same period of 1921), but prices were probably barely remunerative even to the large producers. Lead mining changed but little, exports of lead bars being 56,800 t. in the first eight months of 1922; some development by French and German companies has taken place. A discovery of mica has been reported in the neighbourhood of Garrucha, and platinum is also said to have been found near Ronda. Some oil prospecting has been carried out and several companies have been formed. Progress has been made with hydro-electric works, and an increase of 80,000 h.p. has brought the available developed total to 800,000 h.p., about one-tenth of the capacity of the Peninsula. A factory to produce 6000 t. yearly of esparto cellulose has been working in Granada with a power installation of 4400 h.p., part of which will be used in the production of the soda required.

Trade in 1922 was stagnant, and imports amounted to 2787·6 million pesetas and exports to 1449·2 mill. pes.; trade items, including minerals, etc., imports, 340·7 mill. pes., exports, 157·2 mill. pes.; metals and manufactures, imports, 213·4 mill. pes., exports, 162·6 mill. pes.; chemical products, etc., imports, 253·0 mill. pes., exports, 111·9 mill. pes. Foreign competition has been serious; Germany, however, lost a large part of her trade with Spain during the year. It is hoped that the commercial treaty with Great Britain will lead to improved business.

REVIEWS

Die Elektrometrische Massanalyse. *By* Dr. E. Müller. *Pp. vii* + 159. *Dresden and Leipzig: Theodor Steinkopff*, 1923. *Price* 3*s*. 5*d*.

The possibility of electrometric titrations depends upon the facts that at the end-points of the ordinary complete reactions used in volumetric analysis the concentrations of an ion which has been diminishing steadily in proportion to the addition of the titrant, suddenly diminishes in a very high ratio, with the last few drops at the end-point, and that the potentials of electrodes reversible with respect to these ions show a great jump at these points. A silver electrode in normal ionic $AgNO_3$ when titrated with KCl solution begins at the normal potential $O^EAg = +0{\cdot}80$ volts and at the end-point reaches a potential given by $E_u = E_o + 0{\cdot}058 \log. (Ag^{\cdot})$, and $(Ag^{\cdot}) = LAgCl = 1 \times 10^{-5}$ approximately, so that $E_u = 0{\cdot}80 - 0{\cdot}29 = +0{\cdot}51$. This is the simplest case, but the potentials of suitable electrodes in many titrations can be thus defined in terms of normal potentials and the equilibrium constants at the end-points. All oxidation-reduction reactions can be expressed by the general equations :— $aA_h + bB_n = a_lA_n + b_lB_h$ in which " h " is the higher state of oxidation and " n " the lower. Of the theoretical part of Dr. Müller's book, which is both full and careful, the chief criticism which can be made is that the symbols for various kinds of potential with their subscripts are unnecessarily numerous and not always in accord with current usage.

In the practical part sufficient details of the physical measuring apparatus (*i.e.*, the potentiometer outfit) are given, as well as many valuable hints, which are not to be found collected in any other book on the procedure in different cases. All the ordinary volumetric titrations can be undertaken, mainly with the aid of the silver, platinum, hydrogen, platinum iodine, platinum oxidation reduction (*e.g.*, Fe‴, Fe″) electrodes, and also new powers are conferred on the analytical chemist: *e.g.*, the titration of cyanide, iodide, and sum of other halogenides successively in the same solution. Silver halides in gelatin emulsions can easily be determined and the method is constantly being extended, *e.g.*, to the determination of silver in protargol, etc. (*cf. J.*, 1923, 806 A).

The book lacks an index, which is particularly needed because the wealth of theory is such that the analyst before becoming thoroughly conversant with the fundamental ideas may have some difficulty in " seeing the wood for the trees." Enough has been said to commend the book both as an interesting application of electrochemical theory and as an exposition of highly ingenious and powerful analytical methods which once installed can hardly fail to save much valuable time.

E. B. R. Prideaux

(1) Radioactivity. *By* K. Fajans. *English translation by* T. S. Wheeler *and* G. E. King. *Pp. xiv* + 138. *London: Methuen & Co., Ltd.*, 1923. *Price* 8*s*. 6*d*.

(2) The Structure of the Atom. *By* Dr. E. N. da C. Andrade. *Pp. xiv*+314. *London: G. Bell & Sons, Ltd.*, 1923. *Price* 16*s*.

Radioactivity has thrown so much light on the structure of the atom that the two subjects will for a long time remain closely connected. These two books are both excellent, and any one who wishes to be acquainted with modern theories should purchase and read both.

(1) Professor Fajans has himself made important contributions to his subject, and his account of radioactivity is lucid and up-to-date. The translation has been well done and the book deals fully with the chemical side of the subject, and gives an accurate and readable account of such part of the physical side as is suited to non-mathematical readers. Isotopes and the structure, or speculations as to the structure, of the atomic nucleus, are treated adequately. The book is well written, well translated and well printed.

(2) Part of the charm of Professor Fajans' book is that he has omitted the difficult mathematical problems and calculations. Professor Andrade has included these and his book is less suited for arm-chair reading, but he has not made it dull or unreadable, and it is not his fault if some of the topics he deals with are inherently difficult. A fair amount of knowledge of the subject is assumed, and consequently he has been able in a book of moderate size to give a very complete account of most of the recent work and hypotheses dealing with the structure of the atom. He explains clearly the γ rays and the disruption of the nucleus; positive rays and Aston's work are well described. The account of X-ray spectra and their connexion with optical spectra is fuller and more intelligible than in any other book the reviewer has come across. There is an excellent account of Bohr's theory of atomic structure and a sufficient account of the octet theory of Lewis and Langmuir. Lewis' conception of electron-sharing has been applied to organic chemistry in various articles which Professor Lowry has contributed to this Journal, and Professor Andrade has briefly dealt with this and some other quite recent pieces of work. The book is as lightly written as is possible for such a grave subject, and shows signs here and there that the author is a human being; he obviously enjoyed writing in an old-fashioned style a dedication to Sir Ernest Rutherford, and in many places the reviewer found simple phrases where ponderous statements would have been possible. The reviewer has been much pleased by these books, either of which may be taken as a model of scientific writing, the one by chemists, the other by physicists.

MODERN GAS PRODUCERS. *By* N. E. RAMBUSH. *Pp. xix*+545. *London: Benn Brothers, Ltd.*, 1923. *Price* 55*s*.

For a long time there has been an increasing demand for a comprehensive book on the subject of "Modern Gas Producers." This has been supplied in no slipshod manner by Mr. N. E. Rambush. Those of us who are working for the complete elimination of solid fuel in all heating processes wherever possible, not only for the purpose of attaining higher thermal efficiencies and better control of heating conditions, but also for the purpose of eliminating altogether the smoke nuisance, are now labouring under a deep debt of gratitude to the author of this voluminous book for the excellent way in which he has treated his subject.

Producer gas has an enormous range of application, and as it can be made at a much lower cost per therm than town's gas can be bought, owing very largely to the cost of distribution, the problems connected with producer-gas production and use should receive as much attention at the hands of our technicians as those connected with the production of town's gas.

This book deals with the general subject of fuel utilisation, the theory of the production of producer gas, practical considerations in the working of gas producers, various types of producers for special purposes, the cleaning and distribution of producer gas, the technical control of producer-gas working, and a useful outline of the methods of utilisation of producer gas. One of the most valuable sections is that containing the conversion tables of particular application to this subject, and the excellence of the "References" still further enhances the value of the book.

The book can be recommended as being thoroughly sound, and the result of a wide introspective experience in the construction and running of producers of all types.

It is inevitable that differences of opinion will exist between technicians on such a wide subject. On page 2 the author states that only 20 to 25 per cent. of the total heat content of the solid fuel is obtained in a gaseous state when coal is carbonised in gas works or in coke ovens, when it is general knowledge that efficiencies of up to 33 per cent. are obtainable in high-temperature carbonisation processes. On the same page, paragraph B, blue water gas is stated to have a normal heating value of 300 B.Th.U. *nett* per cb. ft., whereas normal water gas is usually about 300 B.Th.U. *gross* per cb. ft.

The discussion on the correct definition of "producer" efficiency is very timely, but one regrets, for comparison's sake, that the author has not dropped the "gas" efficiency definition, and wholly gone out for an "overall" efficiency. It should not be forgotten, however, that as producers are particularly suitable for working with low-grade fuels as regards size and quality, efficiency is not always of prime importance. Special mention is made of the importance of grading of fuels for producer work.

Much valuable information is also given relating to liquid slag producers. There is likely to be a big development in this direction in English practice, but no mention is made of the Wollaston producer.

In discussing firebrick materials, the only one to which the fusion test is attached is that of Stourbridge material. Surely there is ample information available from which the author could have included fusion tests for the other materials mentioned?

The results of tests with steam-jet blowers have not been obtainable in this collated form, so far as the reviewer's knowledge goes, from any other source.

The chemical control and testing of gas producers is well handled, but one would have liked more detailed information of methods of sampling solid fuels, these being of much more importance than the actual tests themselves. The author suggests that the water used in gas sampling bulbs should be acidified in order to *prevent* the absorption of carbon dioxide. Acid does not prevent the absorption of carbon dioxide by water. It simply reduces the amount of absorption.

The section dealing with the question of the utilisation of producer gas, though comparatively short, is perhaps one of the most useful parts of the book. It is acknowledged that producer gas, because of its low flame temperature, cannot give as good results at high temperatures as either blue water gas or coal gas, but its range of usefulness still remains very great.

This book should be found on the shelves of all fuel engineers and others interested in the better utilisation of solid fuel.

E. W. SMITH

CHEMICAL INDUSTRY CLUB

The annual dinner of the Chemical Industry Club will be held in the Connaught Rooms, Great Queen Street, W.C. 2, on Monday, November 26. Several men prominent in the chemical world will be present. Tickets, price 15s. each, may be had from members or the secretary of the club.

With great regret we learn of the death of Mr. William Thomson, F.I.C., an original member of the Society of Chemical Industry who had served many times on the Committee of the Manchester Section. An obituary notice will appear in a later issue.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Oct.* 4)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Paper (tender)	8740/F.L./P.N.
,,	Oils, rubber (tender) ..	8495/F.L./G.P.
Australia	Steel pipes (tender) ..	12250/E.D./E.C./2
British India	Iron, tyres (tender) ..	*
South Africa	Scientific instruments ..	918/6/F.G./C.C./2
,,	Copper tubing (tender)	12225/E.D./E.C.
,,	Brass pipings, copper sheets (tender) ..	12224/E.D./E.C.
,,	Ash-crushing machine (tender)	12227/E.D./E.C./2
Spain ..	Tinplate, leather ..	372, 373
Switzerland	Drugs	375
United States	Iron and steel	377

* Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1.

TARIFF CUSTOMS EXCISE

Australia.—The deferred duties on hoop iron have been postponed to March 31, 1924.

Germany.—The current issue contains a list of goods subject to export licence, including animal fats, leather, oils, sugar, magnesite, gypsum, cement, talc, felspar, ores, tars, chemical and pharmaceutical products, artificial silk, building materials, paper, metals, iron and aluminium. The internal tax on sugar has been increased.

United Kingdom.—The current issue contains a list of goods of which export is prohibited.

United States.—Investigations are being made in respect of the cost of production of crude magnesite, adonite, arabinose, dulcite, inulin and other saccharides, and amido acids not originating from coal tar.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains the improvement recently recorded and trade seems now to be somewhat steadier. There is nevertheless no great volume of business, as it is mainly confined to spot orders and requirements for the immediate future.

The actual state of the textile trade, which always has a tremendous effect on the home consumption of chemicals, is still somewhat of an enigma; reports from the North and Midlands indicate that certain mills are on full work, while others are very short of orders. There is no indication that any improvement of a permanent nature has arrived and probably only a certain class of goods is in demand. Any change for the better in textiles is being looked for with great eagerness by the chemical trade.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric ..	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw. ..	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali ..	£7 10s. per ton, spot delivery. General export demand good, particularly from the Continent.
Arsenic (White) ..	£72—£73 per ton. Not much doing.
Bleaching Powder ..	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride ..	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Copper Sulphate ..	£25 per ton. Dull.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate ..	5¾d.—6d. per lb. d/d.
Potass. Chlorate ..	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.

Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Business in this section is generally on the dull side.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	5s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	Carload lots 8¼d. per lb. Less quantities 9¼d. per lb. ex wharf London. Supplies exceed the demand and prices have been reduced by 1d. per lb.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

The volume of trade is small and, except in acetates, there is very little life. The tar market seems slightly weaker.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. Slightly weaker.
Brown Sugar of Lead	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Good demand. Market firmer. Limited quantities only available for prompt delivery.
Crude 60's	3s. 6d.—3s. 8d. per gall. Good demand for spot delivery. Supplies limited.
Acid Cresylic—97/99	2s.—2s. 2d. per gall. Steady demand.
Pale 95%	1s. 10d.—2s. 4d. per gall. Good quantities on offer.
Dark	1s. 7d.—2s. per gall. Fair parcels offered.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. Few inquiries, but no business.
Anthracene Oil—	
Strained	9d.—11½d. per gall. Supply short.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 7d.—1s. 8d. per gall. Little business passing.
Pure	1s. 10d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9½d. per gall. according to grade and district. Demand still good.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d.—1s. 3d. per gall. Market very quiet owing to rubber trade slackness.
Solvent 90/190	1s. 3d.—1s. 4d. per gall. Market very quiet.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. More inquiry, Difficult to meet demand.
Whizzed or hot pressed	£10—£12 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	120s.—130s. per ton, according to district and time of delivery. Several inquiries. Market firm.
Pyridine—90/140	21s.—21s. 6d. per gall. Market very strong.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Slightly more business has been done in aniline dyes during the present week. This has been more especially noticed during the latter half of the week. Whether this improvement will keep up or no it is very difficult to say. It is very unlikely that any great improvement will take place in the near future, as there seems to be no change in the depressed state of the textile industry. Prices do not vary.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.

Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 7d.—1s. 8d. per lb. Good demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Prices slightly reduced and a better demand is experienced.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£90 per ton d/d.
Dinitrotoluene—48/50° C	8d.—9d. per lb. naked at works.
66/68° C	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

A firmer tendency is shown all round, and more confidence may be placed in the immediate future, as supplies generally are keeping pace with the demand without accumulation of large stocks.

Acid, Acetic 80% B.P.	£52 10s. per ton.	
Acid, Acetyl Salicylic	3s. 3d. per lb. Good demand. Firm market. Price likely to advance owing to increase in raw material. Supplies limited and Continental position also firmer.	
Acid, Benzoic	2s. 6d. per lb. Firmly held, but very little inquiry.	
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.	
Acid, Citric	1s. 6½d. per lb., less 5%. Poor demand. Market dominated by weak holders and bad season.	
Acid, Gallic	3s. per lb. for pure crystal. Market steady.	
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb., according to quantity.	
Acid, Salicylic	2s. 2d.—2s. 3d. per lb. for 5 cwt. lots. Firm market in sympathy with other salicylates. Good inquiry. Supplies not heavy.	
Acid, Tannic	3s. per lb. for B.P. quality. Price somewhat lower.	
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Demand fair and likely to improve. Raw material dearer. Prices will probably advance.	
Amidol	9s. per lb. d/d.	
Acetanilide	1s. 7d. per lb. for English manufacture. Extremely firm and demand active.	
Amidopyrin	12s. 6d. per lb. Demand still very poor.	
Ammon. Benzoate	3s.—3s. 6d. per lb., according to quantity.	
Ammon. Carbonate B.P.	£32 15s. per ton.	
Atropine Sulphate	12s. 6d. per oz. for English make. Firmer tone now prevails.	
Barbitone	17s. per lb. for quantity. Demand limited.	
Benzonaphthol	4s. 6d.—4s. 9d. per lb. Slight advance in price.	
Bismuth Salts	A steady market. Carbonate 13s., Nitrate 6s. 11d., Salicylate 10s. 5d., Subgallate 9s. 6d., Citrate 11s. 7d., Oxide 14s. 5d., Subchloride 12s. 8d., Subnitrate 11s.	
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.	
Bromides—		
Potassium	6½d. per lb.	Holders of stock are steadying up prices owing to uncertain position of Continental supplies
Ammonium	7d. ,, ,,	
Sodium	7½d. ,, ,,	
Calcium Lactate	2s. 6d. per lb. for best makes. Better enquiry.	
Chloral Hydrate	3s. 10d.—4s. per lb. In active demand. English makers are oversold.	
Chloroform	2s. per lb. for cwt. lots. Higher prices expected.	
Creosote Carbonate	8s. lb. Demand negligible.	
Formaldehyde 40%	75s. per cwt. ex wharf London. Slightly less for large orders.	
Guaiacol Carbonate	9s. 6d. per lb. Considerably firmer. Stocks low.	
Hexamine	3s. 9d. per lb. Spot parcels have been cleared and little coming forward.	
Homatropine Hydrobromide	30s. per oz.	

Hydroquinone ..	.. 3s. 3d.—3s. 6d. per lb. Now asked, according to quantity and holder.
Iron Ammon. Citrate	.. Reduced by 2d. per lb. 2s. 3d. per lb. for cwt. lots. 2s. 4d. for 28 lb. lots.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net. Prices reduced.
Magnesium Oxide—	
Light Commercial	.. £80 per ton, less 2½%. Prices reduced.
Heavy Commercial	.. £27 per ton, less 2½%. Prices reduced.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	.. A.B.R. recryst. B.P. 75s. per lb.
Mercurials ..	.. Steadier. Quicksilver rather better.
Methyl Salicylate	.. 2s. 6d.—3s. per lb. Much firmer for English or imported, in view of seasonal advance now in progress.
Methyl Sulphonal	.. 14s. 6d. per lb. No demand.
Metol	.. 8s. 9d. per lb.
Morphine and Salts	.. Prices again advanced owing to dearness of opium. Alkaloid: Cryst. 14s. 8d., Precip. 14s. 5d., Acetate 11s. 6d., Hydrochlor. 11s. 6d., Sulphate 11s. 6d., Tartrate 14s. 5d. per oz.
Paraformaldehyde	.. 3s. 6d. per lb. Quiet.
Paraldehyde ..	.. 1s. 5d.—1s. 5½d. per lb. Average price in 5 lb. bottles.
Phenacetin ..	.. 6s. 3d. per lb. Demand steady. Moving to higher prices.
Phenazone ..	.. 7s. 6d. per lb. Firm. Stocks none too plentiful.
Phenolphthalein	.. 6s. 6d. per lb., according to quantity and holder. More active.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide	.. 3s. per lb. English makes are meeting foreign competition.
Potass. Iodide ..	.. 15s. 8d.—16s. 2d. per lb. Good demand.
Potass. Metabisulphite	.. 8d. per lb.
Potass. Permanganate	.. 10d. per lb. for B.P. crystal. Price would be shaded for ton lots.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 6d. per lb. Business poor.
Salol	.. 3s. 3d. per lb. Limited demand. Price would be shaded for quantity.
Silver Proteinate	.. 10s. per lb. A weaker market.
Sod. Benzoate ..	.. 2s. 6d. per lb. Spot price lower than replacement value owing to lack of demand.
Sod. Citrate, B.P.C. 1923	Reduced 2d. per lb. 2s. 1d. per lb. for cwt. lots.
Sod. Hyposulphite— Photographic	.. £15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Methylarsenate	.. 15s. 6d. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	.. 82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate ..	.. Powder 2s. 8d. per lb., and Crystal at 2s. 11d. per lb. Firm, with tendency to rise. Large orders in hand.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal ..	.. 13s. 9d. per lb. Little inquiry.
Tartar Emetic ..	.. 1s. lb. net. Fair demand.
Thymol	.. 13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 11s. 6d. per lb.	
Aubepine ..	.. 14s. ,, ,,	
Amyl Acetate ..	.. 3s. ,, ,,	
Amyl Butyrate ..	.. 7s. 3d. ,, ,,	
Amyl Salicylate	.. 3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol ..	.. 3s. ,, ,,	Higher prices anticipated.
Benzyl Alcohol free from Chlorine ..	.. 3s. ,, ,,	
Benzaldehyde free from Chlorine ..	.. 3s. ,, ,,	
Benzyl Benzoate	.. 3s. ,, ,,	
Cinnamic Aldehyde Natural ..	.. 18s. 6d. ,, ,,	
Coumarin ..	.. 18s. ,, ,,	
Citronellol ..	.. 19s. 6d. ,, ,,	
Citral	.. 9s. 6d. ,, ,,	
Ethyl Cinnamate	.. 10s. ,, ,,	
Ethyl Phthalate	.. 3s. 9d. ,, ,,	
Eugenol	.. 10s. ,, ,,	
Geraniol (Palmarosa)	.. 37s. 6d. ,, ,,	
Geraniol	.. 6s. 9d. to 13s. 6d. per lb.	
Heliotropine ..	.. 8s. per lb.	
Iso Eugenol ..	.. 15s. per lb.	
Linalol ex Bois de Rose	.. 18s. 6d. ,, ,,	
Linalyl Acetate ..	.. 18s. 6d. per lb. Considerably cheaper.	
Methyl Anthranilate	.. 8s. 6d. per lb.	
Methyl Benzoate	.. 6s. ,, ,,	
Musk Ketone ..	.. 40s. ,, ,,	
Musk Xylol ..	.. 12s. 6d ,, ,,	
Nerolin	.. 4s. ,, ,,	
Phenyl Ethyl Acetate	.. 10s. ,, ,,	
Phenyl Ethyl Alcohol	.. 16s. ,, ,,	
Rhodinol	.. 47s. 6d. ,, ,,	
Safrol	.. 2s. ,, ,,	
Terpineol ..	.. 3s. ,, ,,	
Vanillin	.. 22s. 6d.—23s. per lb. Firm and steady demand. Raw material dearer.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 14s. 6d. per lb.
Anise Oil	.. 1s. 10½d. ,, ,,
Bergamot Oil ..	.. 12s. 6d. ,, ,, spot.
Bourbon Geranium Oil	.. 35s. ,, ,,
Camphor Oil ..	.. 80s. ,, ,,

Cananga Oil, Java	9s. " "
Cinnamon Oil, Leaf	4½d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 2d. " "
Ceylon	4s. per lb. Very little on offer, too many parcels arriving spirit. These have been seized by the Customs.
Clove Oil	8s. 6d. per lb. This market is now firmer.
Eucalyptus Oil 70/75%	2s. 9d. per lb.
Lavender Oil, Fresh	21s. per lb. Reliable offers are difficult to obtain and very high prices for new crop oil seem inevitable.
Lemon Oil	2s. 10d. per lb. Very high prices are being asked at the source.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	24s. per oz.
Palma Rosa Oil	23s. 6d. per lb.
Peppermint Oil—	
Wayne County	15s. per lb. Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	8s. per lb. Dearer.

TRADE NOTE

Consumption of Acetic Acid in Malaya

Except on native rubber holdings and, possibly, one or two large estates, all rubber latex produced in British Malaya is coagulated with acetic acid. During the war, when supplies of acetic acid were difficult to obtain, sulphuric acid came into general use. This acid is cheaper than acetic, but its use has been condemned by the Department of Agriculture of the Straits Settlements and Federated Malay States and also by the Rubber Growers' Association. The subjoined table shows that the value of acetic acid imports has risen enormously since 1920). In 1921 Canada furnished almost 50 per cent. of the supply, but by 1923 she has altogether ceased to compete in the market. The bulk of the acid is now supplied by European Continental countries. Details as to the respective quantities exported by the different countries of the Continent in 1922 and 1923 are not yet available, but in 1921 the Netherlands and Germany were the only two European Continental countries exporting the acid to Malaya. The value of imports of Japanese acetic acid rose enormously in 1922, but fell during the first half of the current year. The following table shows the values of imports of acetic acid in 1921, 1922, and the first half of 1923:—

	1921	1922	1923. (6 months)
United Kingdom	£390	£7,920	£4,792
British Possessions	11,332	540	nil
Continent of Europe	3,819	80,347	52,213
U.S.A.	5,565	751	1,017
Japan	2,366	29,121	4.450
Other Countries	nil	245	nil
Total	£23,472	118,924	62,472

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, OCTOBER 19, 1923 No. 42

EDITORIAL

CHEMICAL ENGINEERS—so we gather from letters we receive and articles we read—are imperfectly understood by many chemists. This is not necessarily the fault of the chemical engineers; there are some chemists, who do not even understand editors, the most guileless individuals the rain ever beats upon. Most of those chemical engineers we know are engineers who have specialised in the plant required by chemical manufacturers; many are not, and do not profess to be, chemists; sometimes they repudiate such an insinuation with fervour; on the other hand, they are familiar with chemical terms and chemical processes and with the machinery and plant which is used in them. If they are not the rose they are certainly found in the vicinity; we are told that one of the most pathetic sights to be seen in Whitehall Court is a young chemical engineer helping a prosperous chemical manufacturer on with his overcoat. We are not thinking of the story of Sir Charles Tennant's butler helping the departing guest in a similar way; the pathos of the sight we have mentioned is deeper. We ourselves fail to see the nervousness of the chemist concerning the engineer. If the engineer is able to be of service to the chemical manufacturer he will be employed and may even become liable to super-tax; if he is not useful to the chemical community he will be obliged to adopt some other livelihood. He will discard his physics and take up instead psychology, which Huxley—we think—described as a phantasm generated by the fermentation of the dregs of theology. We see no sign of such a cruel fate; some departments of the chemical industry are unusually suitable for study by chemical engineers; the chemical engineers have made valuable contributions to our journal and have also published elsewhere important generalisations on topics of interest to chemists—the recent monograph on "Industrial Oxygen" by T. Campbell Finlayson is a notable instance. Whether anyone can at the same time be both a competent engineer and a learned chemist is a problem of minor importance; whether the species of intellect which emits chemical research is identical with that of the man who can design a new coke-oven or filter is a point for the psychologist. The important question is where and how can the chemical manufacturer obtain the most useful and modern information on those engineering problems which he encounters.

* * *

It used to be said that good wine needs no bush. If this were ever true, which we doubt, it was in the days before railways, motor-cars or charabancs were invented and when the lads of the village needed no external assistance in finding the hostelry or the vintner best able to gratify their palates. At the present time goods find their way to distant places and both town and country are full of people who are ignorant of such vital facts as the best sources of supply. It seems to us that the best require advertisement more than the bad or the mediocre; and we think the public is glad to be guided—by a sure and impartial hand—to what is valuable and important. Among such excellent features to which attention may be directed is the dinner of chemists on the 31st of this month. We are informed that Lord Wargrave will propose the toast of "Chemistry and the Nation," to which Sir William Pope will reply; Mr. R. G. Perry is to propose "Our Chemical Organisations," to which the President of the Chemical Society will reply, and Dr. E. F. Armstrong is to propose "The Universities," to which the Vice-Chancellor of the University of Cambridge will reply. It is confidently predicted that these speeches will combine brevity with concentration and that the speakers have taken to heart the advice of the late Mr. Weller so to end that the audience wishes for more. There will be some excellent music of types to please both the fine and heavy chemists. What man of knife, or teeth, can keep away from a gathering! It will do much to promote the causes of civilisation and chemistry, and it seems to us quite possible that the evening will be more than a mere banquet. In any case, a considerable number of the well known figures have expressed their intention of coming and many are bringing ladies. More than a hundred have already taken tickets, and as many people do not make up their minds until a few days before the actual date it seems pretty certain that there will be a large attendance. The first duty of chemists is to know each other, it is so easy to know the science afterwards. We have heard it said that it is more important to know where the law can be found, than to know the law.

* * *

There is something else the excellence of which should be well advertised. We are thinking of British chemistry. Few of us recognise how good it is, but the Scientific Section of the Chemical Exhibit at the British Empire Exhibition next year should bring it home to us. We have always had our share of great names ever since the time of Robert Boyle, "the father of modern chemistry and brother of the Earl of Cork." But it is not generally realised what a volume of high-class work emanates at the present time from our Universities and from other laboratories in many parts. The chemical exhibit will surprise us all in demonstrating the variety and excellence of what is manufactured in this country, and if we reflect on the contribution which Great Britain has made to pure chemistry during the last score of years we shall find that our intellectual activity is of the first order. The object of the scientific section is to prove in no uncertain manner that the research conducted here is not merely adequate for the industrial applications of chemistry but is an achievement of which any country, however great, wealthy and learned, may be justly proud. Our industrial magnates and our statesmen need not fear, nor need our rivals hope, that our men of science cannot easily keep pace with the needs of the State and show a handsome surplus for the benefit of future generations. This scientific section is being organised by a committee fully representing the many branches of the science. Its chairman, Dr. Herbert Levinstein, has taken infinite pains over its organisation, and has tackled this difficult piece of work with youthful energy and pardonable enthusiasm. The whole field of chemistry, including physical chemistry, agricultural chemistry, bio-chemistry and so on is being covered, and the outstanding men in the various branches are directing and assisting the exhibit with most commendable assiduity. We have been privileged to learn much of what is taking place in this matter, and we believe that this section will be a wonderful representation of modern British chemistry.

ARTIFICIAL RESINS, VARNISHES AND LACQUERS

By REX FURNESS

The mists of empiricism which surrounded the manufacture and applications of artificial resins of the phenol-formaldehyde type were largely dissipated by the scientific work and technical ingenuity of Baekeland, Redman, Le Bach and others, only, however, to gather again around the substitute resins, lacquers and varnishes called into being as a result of war-time scarcity of natural resins and lacs. It was almost inevitable that little discrimination should be exercised during such periods of economic stress, so that coumarone and indene resins, naphthalene-formaldehyde condensation products, acrolein and furfural resins and so forth were manufactured with little regard to scientific control of quality or composition. Moreover, all-embracing claims as to their potential applications were made, standing in strong contrast to the proven statements as to the value of certain phenol-formaldehyde products.

It is quite comprehensible, therefore, that the high level of war-time production of coumarone resins, namely, from 10,000 to 12,000 tons per annum in Germany, should have sensibly declined in post-war years. Increased attention is, however, being paid to the control of raw materials and methods of manufacture of these useful resins, so that the production figure shows a distinct tendency to rise both in the United States and Germany as the properties of the standardised products are more fully appreciated.

The artificial resins as a class are of great utility in the varnish and lacquer industry, whilst the insoluble and infusible types have dielectric properties which have won them an established position in the electrical world. It has been possible to produce resins closely resembling various natural gums, lacs and resins, so that their employment in direct substitution may be expected to continue, even when normal supplies of the natural products are available at pre-war prices. On the other hand, special processes have been developed in which the effects of shellac and the like are imitated or surpassed, recourse being had to different types of synthetic resins. Thus, stoving enamels employing fusible phenol-formaldehyde condensation products as a principal constituent have become popular in the lacquered metal trade, a lacquered finish being formed which is harder, more durable, tough and elastic than that ordinarily obtained with the aid of natural shellac.

The varieties of artificial resins now available —phenol-formaldehyde resins and coumarone resins in particular—are so extensive and their individual properties so standardised that their use in the electrical and chemical industries as insulating and acid-resisting materials, respectively, and their employment as gum and lac substitutes and for the manufacture of moulded articles—pipe stems, toilet articles, acid-resisting transparent apparatus, constant measurement screws, gramophone records and many other things—will undoubtedly increase.

In this article it is proposed to deal with the constitutions and methods of controlled manufacture of artificial resins, rather than to detail the suggested applications, which are well cared for in the manufacturers' catalogues, brochures and in inspired articles in the trade Press.

Coumarone Resins

The fraction of normal coal-tar distilling between about 160° and 200° C. contains unsaturated hydrocarbons such as coumarone, indene and their homologues, in addition to the better known benzol hydrocarbons (naphthas), and substances containing oxygen and nitrogen. If, after the removal of the latter by washing with alkali and acid, respectively, the naphtha is treated with concentrated sulphuric acid in small amounts the unsaturated hydrocarbons are polymerised whilst a certain amount of sulphonation occurs. The dark acid layer on dilution gives an inferior resinous product, containing the sulphonated products, whilst the hydrocarbon layer may be worked up for the production of coumarone resins. On distillation in steam the benzols are carried over, leaving a resinous material, whose colour, hardness and solubility depend, *inter alia*, upon the extent of distillation. The products obtained broadly in this manner constitute the coumarone resins of commerce.

Other polymerisation agents may be used, such as salts of zinc, aluminium and tin, particularly tin tetrachloride, or a process combining polymerisation and oxidation may be employed, linoleates, resinates, etc., being used as catalysts. Again, oxidation may follow polymerisation, but by far the greater part of the coumarone resins available result from a modified type of the simple sulphuric-acid polymerisation method first indicated.

It is, then, to the improvements effected in this process that brief attention will be paid. If the original distillation of the coal tar is more carefully effected, and a fraction containing essentially only coumarone and indene as representatives of the unsaturated hydrocarbons be taken for sulphuric acid treatment, the resins finally obtained, *ceteris paribus*, are harder and lighter in colour than the ordinary types, resulting from the polymerisation of a fraction containing coumarone homologues. The greater definition of the product and the decreased possibility of the formation of low-melting eutectic mixtures contribute to the enhanced hardness of the resin. This result may be achieved in another manner by a fractional polymerisation. Thus, the treatment of a certain tar fraction with relatively dilute acid (50 Bé H_2SO_4) results in the polymerisation of the content of styrolene and dicyclopentadiene to hard black resins. After separation of the unconverted coumarone and indene in solution in naphtha by distillation, the distillate is treated with strong acid (66 Bé) in controlled quantities and at a definite temperature, say 50° C. The unsaturated hydrocarbons are polymerised to resins, which are recovered in the usual manner.

Apart from the control of the raw material selected for polymerisation, the details of the various operations have been surveyed and control measures adopted which increase the value of the final resin. The washing of the naphtha containing resin after separation of the acid sludge is a delicate operation and emulsions are formed only too readily. Not only is this troublesome in the manufacturing operation, but the final product is liable to contain acid and sulphonic derivatives, which it has been impossible to remove from the resin solution. These affect the colour and hardness of the final resin. Fractional neutralisation, neutralisation by means of solid alkalis, neutralisation of diluted solutions and the like have assisted materially the clean separation of resin solution and acid sludge, but there appears to be a favourable opening for the introduction of electrical or centrifugal separation devices, the addition of reverse colloids and, generally, of those methods of quick and complete emulsion breaking which have proved so effective and economical in oilfield emulsion treatment, soap stock separation, and similar operations. (*Cf.* this *J.*, 1922, 346 R.)

Again, the temperature at which polymerisation is effected influences the product, and at least one process suggests artificial cooling of the naphtha fraction during the addition of sulphuric acid. After removal of the naphtha by steam distillation, not omitting acid treatment and washing, the residual resinous product may be freed from the last amounts of solvent by heating *in vacuo* and, generally, attention to the temperature conditions during this stage is reflected in the quality of the final resin.

The coumarone resins are, as a class, soluble in naphtha, benzene hydrocarbons and turpentine, but are insoluble in alcohol. They are fusible and approach in many physical properties the natural gum resins; hence their value in the varnish industry. They also find applications as adhesives, in printing-ink manufacture, although their suggested use as varnishes for electrical insulation cannot be recommended in view of the availability of the fusible phenol-formaldehyde resins, noted in the following section. Further applications are being sought, and the modern standardised products —one American company manufactures nine types varying in melting point up to 150° C. and in colour from pale yellow to a dark amber —can be relied upon to provide constant, cheap and effective substitutes for many fossil resins, the supply of which is, in many instances, rapidly diminishing.

Phenol-Formaldehyde Condensation Products

As in the case of coumarone resins, it is a simple matter to produce a polymerised product if the quality, constancy of composition and general excellence of service capacity are left unconsidered. The manufacturer has, however, profited by the scientific investigations and technical control methods developed, so that first-class, constant quality products of many varieties are available in large quantities. Their uses in the manufacture of moulded articles of many kinds, as electrical insulators, for making insulating varnishes, as acid-resisting coatings for certain types of chemical apparatus, in the production of precision screws which have no "cold flow," and in many other fields depend upon their relative solubility or insolubility in solvents, as the case may require, their infusibility or fusibility, and their resistance to attack by acid and alkali. It will appear in the subsequent discussion of constitution that many products can be produced with definite properties which fit them for specific uses.

If phenol and formaldehyde be mixed in such amounts as to insure the presence of excess of one mol. of the former per mol. of the latter, reckoned as HCHO, the formation of oxybenzyl alcohol is readily effected on heating, but catalytic agents may be added if desired. On continued heating a molecule of water is lost between the phenol groups of two molecules of the phenol alcohol and a "saliretin" resin is obtained. This resin, especially in the presence of excess of phenol, is fusible, soluble in alcohol and acetone, and easily coloured by oxidation. Further heating causes polymerisation, and a final resin can be obtained which is apparently infusible, although it will soften on heating, and is insoluble in alcohol but swells in acetone. In no way can this be compared to the final product obtained in the reaction between phenol and excess of formaldehyde, the so-called Bakelite C, an insoluble, infusible resin, resistant to acid and alkali.

The saliretin resins occur in many types, according to the extent of dehydration and polymerisation of the phenol alcohols originally formed and to the amount of excess phenol held in physical admixture. The formation of the first product of reaction, a phenol alcohol, may escape notice on account of its immediate dehydration, the heat of reaction being considerable. These resins differ in many ways from those which are conveniently designated here as Bakelite resins the fusible saliretin resin differs in many respects from the so-called Bakelite A, and the final polymerisation product of the saliretin resin first formed differs from the infusible, insoluble Bakelite C, and since these are the more important commercially, they will be discussed more fully.

Bakelite Resins

A simple description of the formation of a Bakelite resin may indicate the general lines of production.

If a mixture be made of equal amounts of phenol and formaldehyde solution (40 per cent.), thus ensuring more than one molecule of the latter per molecule of phenol, the formation of two layers is soon observed upon heating. As the water is evaporated either from the separated or non-separated condensation product, the product becomes thicker, and finally a transparent viscous resin, solidifying on cooling, can be obtained, which is soluble in alcohol. On continued heating the final infusible, insoluble Bakelite resin is obtained, although great care is required so to control the exothermic reaction that frothing does not occur. (The effective control of the final hardening presented one of the most difficult of the many technical problems which confronted the manufacturers.)

It is suggested by Baekeland that the reactions may be represented by the equations :—

1. Dehydration of the phenol alcohol—

$$2CH_2OH{\cdot}C_6H_4{\cdot}OH = H_2O + CH_2OH{\cdot}C_6H_4{\cdot}O{\cdot}C_6H_4{\cdot}CH_2OH.$$

2. Reaction with formaldehyde—

$$3C_{14}H_{14}O_3 + HCHO = 3H_2O + C_{43}H_{38}O_7$$

3. Final polymerisation—

$$4C_{43}H_{38}O_7 = (C_{43}H_{38}O_7)_4.$$

Many modifications of the simplest form of the process described above form the subjects of patented processes. The variations in the original methods of Bayer (1873) and of that in the patent of Smith (1899), concern the methylene derivatives used and the catalyst, etc. Thus, in place of formaldehyde, trioxymethylene, hexamethylene tetramine, or paraformaldehyde may be used, and almost any acid or base may be taken as catalyst, although Baekeland points out that the action of acid and basic catalysts is essentially different. Ammonia, ammonium salts, amines and volatile basic substances may cause some trouble in the final hardening stage (*v. infra*), so that it is often preferred to employ small quantities of the solid alkalis as catalysts. It is impossible to do more than mention catalysts, for their number is legion—at any rate in patent literature—and, moreover, several catalysts recently suggested appear to possess no special advantages over those originally employed. It is possible to produce excellent qualities of fusible or infusible resins by the original method, using small amounts of solid bases as catalysts, for instance, and it is in the elaboration of control methods that success has been won.

If the product of condensation and reaction with formaldehyde, as represented by the fusible resin Bakelite A, be heated rapidly to

150° C., the polymerisation becomes so violent and the heat evolved so intense that foaming occurs, and the hard resin immediately formed is porous, rough and disfigured by the escaping water vapour, formaldehyde or volatile bases. By carrying out the polymerisation in closed moulds, in apparatus in which a counter pressure is created by means of an inert gas, or in hydraulic presses, the infusible resin obtained is free from defects. This phase of the manufacture is of considerable importance, as it was one of the determining factors in the successful technical production of synthetic resins. To-day, a better control of the first stage of polymerisation has enabled the final hardening to be effected at atmospheric pressure and at relatively low temperatures, in contrast, for instance, with a pressure of 100 lb. per sq. in. and a temperature of 150° C.

In addition to the normal soluble and insoluble resins which are produced regularly to a standard specification and possess constant properties, there are available several derived products. Suitable fillers have been discovered, such as wood flour or sawdust, which increase the elasticity and resistance to shock of the final product and generally confer improved physical properties upon the moulded articles. It has recently been found possible to produce homogeneous resin-rubber compounds with the aid of suitable mixed solvents. Laminated resins are perhaps the latest addition to the varieties now in commerce, and these find application, *inter alia*, as substitutes for thin hard rubber used as insulating material in the automatic telephone.

The dielectric properties of the resins are utilised in the moulded forms of the infusible type resins, in the varnishes obtained from the soluble types, and in products from paper or fabrics impregnated with the resins.

OTHER ARTIFICIAL RESINS

Several other types of resin substitutes have recently been described and deserve brief notice here. Production of these resins on a large scale, however, has not yet been attained, and it will be a difficult struggle to cut out the Bakelite type and coumarone resins, now so firmly established. Scientific work and careful technical control of production are essential before any attempt be made on the part of salesmen to introduce the newer resins. In the end, however, they should win a place in industry, for the sources of raw materials are abundant and varied, and their cost is relatively low.

FURFURAL RESINS

Furfuraldehyde has recently come upon the market as an industrial chemical, selling at less than a shilling a pound. It is made by hydrolysing certain waste cereal products, such as corn and maize cobs, oat hulls, etc., either in the presence or absence of acid. The aqueous distillate obtained can be rectified with relatively little difficulty. The sources of the necessary pentose-containing waste materials are wide, and it can confidently be expected that supplies of furfural will keep pace with demand, without any rise in the cost of the aldehyde.

The condensation of furfural with phenol, cresol or naphthol, readily occurs in the presence of catalysts, such as halogen acids, phosphoric acid, sulphuric acid, the chlorides of copper, zinc, aluminium, ammonium, etc. Black resins result, which are insoluble in acid and alkali even at boiling temperatures, and in all organic solvents except tetrahydronaphthalene.

The resins are capable of taking a high polish and can be turned upon the lathe. Fillers such as sawdust, kieselguhr, etc., may be incorporated into the reaction mixture.

If alkali be employed as the condensation catalyst, the resulting resins are brownish black, and are soluble in organic solvents. These solutions are suggested for use as varnishes, lacquers, and for waterproofing textiles.

Finally, furfural may be condensed with aniline or other amines to give distinctive products.

ACROLEIN RESINS

New methods for the cheap production and complete stabilisation of acraldehyde were worked out during the war by Moureu and Du Fraisse, whose investigations led them to the discovery of the "Anti-oxygens," which are destined to play an important part in the stabilisation of many industrial products such as oils and fats, rubber, dyes, and so forth. Cheap acrolein, capable of storage and transportation without resinification, provides the initial raw material for several soluble varnish resins as well as of insoluble hard resins, broadly of the Bakelite type.

Pure acrolein is polymerised in the cold by means of an organic or inorganic base, or salts of iron or lead, but not by means of an acid. The white precipitate produced is filtered immediately, washed and dried *in vacuo*. The polymerised product is soluble in alcohol but insoluble in water or hydrocarbons. The alcoholic solution dries to a brilliant varnished surface upon suitably prepared wooden or metallic structures.

Pure acrolein may likewise be condensed with a phenol by the aid of a mineral or organic base. The preparation of the artificial resins differs materially from that of Bakelite resins, since no water is present and the reaction occurs in one relatively simple stage. A yield of 100 per cent. is claimed upon simple mixing of the constituents in the presence of a suitable catalyst.

The resins produced are hard, insoluble in most solvents, of high electrical resistance, and can be moulded into desired shapes.

NAPHTHALENE-FORMALDEHYDE CONDENSATION PRODUCTS

Condensation products which have found some application in the German paint and varnish industry may be made from naphthalene and formaldehyde, a mixture of turpentine or refined tar with the product being employed. There would seem to be less prospect of established success for this type of product than any other, and a brief indication of the method of preparation will suffice. A mixture of 100 parts of naphthalene and 80 parts of 30 per cent. formaldehyde is gradually treated with 100 parts of H_2SO_4 (66 Bé). The mixture is heated under a reflux condenser at about 80° C. for several hours, and finally poured into water. The condensation product is washed with water, dilute alkali and finally water again and dried at 80° C. The hardness of the resin substitute varies with the conditions obtaining during its production.

The Bakelite type resins, manufactured by reputable organisations in this country, France, America and Germany, stand pre-eminent in the field of artificial resins, whilst the newer coumarone resins, carefully manufactured, are winning an established position.

Much research lies before the producers of many other types of artificial resins and gums, for the manufacturers of varnishes and lacquers, in particular, are inclined to regard the salesmen who call upon them "et dona ferentes" as suspect as were the Greeks before Troy.

PERSONALIA

The Abbé Taulergne, of Pontigny, has been awarded a silver medal and the sum of 5000 fr. for his scientific work, which includes a method of making three-colour prints, and investigations on radiography, etc.

Alois Walter, chemist to the Waldenburg porcelain works, has been appointed to a professorship in the German State training school for the porcelain industry.

Dr. E. S. Simpson, with the title of Government Mineralogist and Analyst, has been appointed to take charge of a new chemical branch opened on March 1, 1922, of the Australian Geological Survey and Government Analyst's laboratories, under the Department of Mines. This branch covers activities which were previously in large part distributed over separate health, agricultural and mineral laboratories.

* * *

The death is announced of Monsieur Brochet, professor of electrochemistry at the School of Physics and Chemistry of the City of Paris.

From France the death is reported of Monsieur Eugène Renevey, president of the Société d'Electro-métallurgie de Dives.

CO-ORDINATION AND THE ELECTRON

Prof. T. MARTIN LOWRY, F.R.S.

Dr. Main Smith's article on "Chelate Co-ordination" (this vol., p. 847) is of interest, less on account of its detailed criticisms than of the general propositions which are contained in the opening paragraphs. He suggests (i) that Werner's theory has been relegated until recently, by myself amongst others, to the limbo of lost causes, (ii) that it owes "less than nothing" to electrical theories of matter and energy, but (iii) that now that Werner is dead, there is almost a fashion for co-ordination; he also asserts (iv) that since Werner is dead "his co-ordination-theory should remain as he propounded it, built it, defended it and left it." In my own case at least, and I believe in that of many other chemists, co-ordination has "come to its own" largely on account of the factor to which it owes "less than nothing," namely, its intimate relationship to the modern electronic theory of matter. My diagnosis of the failure of Werner's theory to secure earlier the adequate recognition which it deserves would, therefore, be of quite a different character from Dr. Smith's, being based mainly on the limited range of chemistry in which it has hitherto made itself indispensable, on the altogether subsidiary part which it plays outside that range, as well as on the absence during Werner's lifetime of a clear theoretical basis for the facts to which he first directed attention.

(*a*) No chemist who has followed the work of Werner, and more recently of Jaeger, on the optically-active compounds of the metals, can fail to be impressed by the masterly character of the demonstrations whereby the octahedral symmetry of the six co-ordinated groups has been established in compounds such as the double oxalates of the transition-metals. This particular region of chemistry must, in my opinion, be dominated by Werner's conceptions, although one recent text-book of chemistry has been able to keep them in the background even in the volume in which the transition-metals are described. When, however, this particular group of elements is left behind, the usefulness of Werner's conceptions diminishes, as their application becomes less and less securely based on experiment. Thus even copper, although it shows its resemblance to cobalt and platinum by forming a large number of ammines, yields such a bewildering array of addition-compounds that Werner's rules are no longer a clear guide to their composition; and a cautious teacher is obliged to fall back on the old-fashioned molecular formulæ, rather than run the risk of bringing the theory of co-ordination into contempt by overmuch ingenuity in applying it. In the same way, the attempt to express the composition of the whole array of crystalline hydrates by means of co-ordination-formulæ has been marked by an ingenuity which has weakened rather than strengthened the theory. Finally, it is not clear that very much has been gained by replacing round by square brackets in the formulæ of compounds such as $[NH_4]Cl$, or by adding square brackets to formulæ such as $K_2[SO_4]$, except as a means of directing attention to an analogy of composition which might otherwise be overlooked.

(*b*) To organic chemistry Werner's theory contributed during his lifetime very little. It is true that he brings carbon within the scope of that theory by describing it as an element in which "the values of the maximum co-ordination number, and of the principal valencies are the same"; but this conception, although it is of interest to the student of co-ordination, has not aroused any enthusiasm in the organic chemist. Indeed, the theory of overlapping spheres of co-ordination is so much less practical than the earlier pictures of valency that its introduction in the formulæ of organic compounds would in most cases be a positive obstruction to progress, comparable with a reversion to the curly brackets by which the theory of types was expressed more than half a century ago.

In one of the few cases in which Werner suggests a modification of the current theories of organic chemistry, he appears to me definitely to have taken a retrograde step, by writing monomethyl ammonium iodide $(NH_3Me)I$ as $[CH_3\text{-}\text{-}NH_3]I$, and suggesting that whereas the three hydrogen atoms of the methyl group are bound to the carbon by a principal valency, "*the nitrogen atom . . . is bound to carbon by an auxiliary valency.*" I do not know of any facts in support of this view, and can see no justification for repudiating the traditional formula for this compound.

(*c*) As illustrating the limited range within which co-ordination has proved itself essential to the study and teaching of chemistry, one may notice that, in the new edition of Roscoe, Werner's theory is first used on p. 1305 of the second volume, and that its applications are limited to about 200 out of nearly 2400 pages. In this respect my own "Inorganic Chemistry" is not much better, although in writing it I had the utmost desire to do justice to Werner's point of view, which I had accepted many years before. Even under these conditions, however, co-ordination is only discussed in Part IV of the volume, and its applications are limited to seven or eight out of forty-five chapters. In organic chemistry I do not know of any text-book in which co-ordination is even mentioned, although the important work now being done in the Birmingham laboratory may soon make it necessary to remedy this defect.

(*d*) The theory of co-ordination has, however, suffered most of all from the lack of a clear picture of the fundamental factors which promote co-ordination. It is true that the laws of symmetry serve to explain the stability of groups 4, 6 or 8 as compared with 5 or 7 radicals; but, until the electronic theory of valency was developed, I have never seen any clear reason given for the extraordinary stability (to which I directed attention in my last article) of the co-ordinated cobaltic ammines, as contrasted with the non-existence of similar stable ammines of iron or nickel. It would be untrue to suggest that at the present time it is possible to supply a complete theoretical basis for all the phenomena to which Werner directed attention; but it is at least very instructive to compare Werner's own attitude on this matter with that assumed by Dr. Smith. Dr. Smith asserts that since Werner is dead, "his theory should remain as he propounded it, built it, defended it and left it," Werner, however, only claimed "to lay the foundation upon which, in the near future, it will be possible to build a consistent doctrine of valency." He looked forward to the development of "a general theory of valency" which would admit "not only of the deduction of valency-formulæ, but also of co-ordination-formulæ," and added that "the most important and pressing problem of valency resolves itself into the discovery and formulation of the general law which expresses all the combining possibilities of the atom."

So far as I know, this "comprehensive doctrine of valency," as Werner describes it in another passage, was not developed in his lifetime; but I am confident that if Werner had lived to see the modern electronic theory of atomic structure developed, he would have been one of the first to apply it to the phenomena of co-ordination, since he had already given evidence of his interest in electronic chemistry. The best proof of the value of Werner's "Neuere Auschauungen" is surely to be found in the vitality and growth of the theory of co-ordination and not in the embalming or mummification of that theory which Dr. Smith appears to regard as the best tribute to the genius of Werner.

(*e*) Even if the co-ordination-chemist can dispense with the electronic theory of valency (in much the same way as the organic chemist has managed to dispense with the theory of co-ordination), the converse proposition is obviously untrue. In the development of the electronic theory, co-ordination is no longer a mere "second string," to be used only when the ordinary rules of valency break down, but is co-equal with other manifestations of valency. Indeed, there are already indications that the boundary which has long existed between valency-compounds and co-ordination-compounds is about to disappear. In particular, Sidgwick's suggestion that in co-ordinated radicals, such as $PtCl_6''$, the six chlorine ions have given up their charges to the platinum, and in doing so have become united to it by six covalencies (or real "bonds" as G. N, Lewis would call them) exactly as in CCl_4. has in my opinion opened up a new chapter in the study of co-ordination, and may even make it possible to abandon the square brackets in which Werner's theory has been confined for so long, by substituting for them the familiar symbols by which valencies have been represented during the last fifty years or more.

2. (*a*) As regards the controversial part of Dr. Smith's article, there is not much that need be said, since I do not think that his comments affect the main line of argument of my previous article. If I may, however, adopt for a moment the attitude, which Dr. Smith (somewhat unjustly) assigns to me, of a recent convert to co-ordination, I might claim that a dispassionate survey of the data has convinced me that there really are two principal types of co-ordination-compounds. Some metals, of which tervalent cobalt and quadrivalent platinum are types, seem to behave like an electromagnet dipping into a heap of scrap-iron, since they will pick up and hold such a large variety of different types, both of ions and of molecules, that it would be tedious to attempt to enumerate them. On the other hand, however, the masterly work of the Birmingham school has brought into prominence the fact that there is a wide range of metals which can be made to form co-ordination-compounds of high stability, provided that the radicals are properly selected—that selection involving in most cases the choice of an unsaturated ring-forming group occupying two places in the co-ordination-complex. In these cases the functions of metal and radical appear to be reversed, since it is the radical rather than the metal that possesses the special characteristics which lead to the formation of stable compounds. One might indeed think of these radicals as horse-shoe magnets, and assign to the metal the relatively passive part of the soft-iron. The force which binds together the radical and the metal may very well be the same in both cases, and in that sense there may be only one kind of co-ordination, just as there is only one kind of magnetic attraction; but in one case the metal appears to be the main seat of activity and in the other the radical. It is also obviously possible to combine an active metal with an active radical, and so to unite both functions in one compound, just as a compound may at the same time be a sodium salt and an acetate, or an alcohol and an acid.

(*b*) In order to explain the special activity of these unsaturated ring-forming groups, I have made use of Thiele's view that the formation of a conjugated chain is an exothermic process, which can act as a source of energy in promoting chemical changes, such as enolisation. For this application of Thiele's theory there is very strong experimental justification. Thus Sidgwick, in a paper read at the Faraday Society's recent conference on valency, has shown that *eight* of the most active types of co-ordinating radical, including a new type recently investigated in the Oxford laboratory, give rise on co-ordination to conjugated six-atom rings, of which he distinguishes four types according to the elements which make up the heterocyclic ring. I do not, therefore, regard it as necessary at this stage to quote any further evidence in order to refute Dr. Smith's scepticism on this point.

(*c*) My original intention was to describe the two types of co-ordination-compounds as "centric" and "chelate"; but in doing so I should have been obliged to use the word chelate in a sense different from that of its original definition, since I wished to exclude those cases in which the chelate group has no special co-ordinating properties beyond those which are derived from a chemical analogy (to which Dr. Smith draws attention, but which I had not overlooked) to the familiar fact that it is easier to stand steadily on two legs than on one. It was for this reason that I used the word "cyclic" instead. I gather from the title of Dr. Smith's article that he is ready to admit the existence of a special type of co-ordination, provided that it is described as "chelate co-ordination." He has, however, given a new definition of the term "chelate" in which the original metaphor of the crab has not merely disappeared, but has actually been reversed, since ring-systems are apparently to be described as chelate, even if they act as a hindrance rather than as a help to co-ordination, flying open like coal-tongs rather than gripping like crabs. This appears to me to be an unfortunate use of an admirable term; but it fully justifies my hesitation to employ this term when defining a group of cases in which a real grip was postulated in the chelate group.

3. (*a*) In my earlier articles I should have made it clear that dotted lines were used only in order to lead the eye from a + to a − charge in its immediate neighbourhood. Under these conditions a large part of the field of force would be concentrated near the line joining the two atoms; but the line itself was not intended to have any physical significance beyond indicating the relatively close association in space of the two opposite charges. This close association may, of course, lead in some cases to the conversion of the electrovalency into a covalency, but that would be shown in the ordinary way by replacing the + — signs by a bond.

(*b*) I may add that the idea, to which I referred in the previous article, that hydrogen may form co-ordination-compounds, in which a proton replaces the ion of a metal, was already used (although perhaps in a slightly different form) by Werner in order to explain the structure of the acid fluorides. The suggestion that it may also be co-ordinated with the more powerful chelate groups is, therefore, not out of harmony with Werner's own conceptions.

SUMMARY

(*a*) The factors which have led to delay in the universal acceptance of Werner's theory of co-ordination are discussed.

(*b*) The view that the development of conjugated rings is an important factor in promoting co-ordination is maintained, in view of the strong experimental evidence on which it is based.

OBITUARY

Dr. J. A. HARKER

Chemists in several countries, and many other people who are not chemists, will be grieved to learn of the death of Dr. John Allen Harker, F.R.S., O.B.E., on Wednesday the 10th inst., after a short illness. Born in Cumberland in 1870, he was educated at the University of Manchester, where he took the degree of M.Sc., and became successively Dalton Scholar and Berkeley Fellow in Physics. He also was a D.Sc. of Tübingen. Entering the National Physical Laboratory he became chief assistant and head of the thermometry division and represented the British Government at the International Petroleum Congress in 1912.

From a national point of view his chief work was undertaken during the war, when he was appointed to organise the work of the Nitrogen Products Committee of the Ministry of Munitions. As director of the Nitrogen Products Research Laboratories he supervised much fundamental work on the fixation of atmospheric nitrogen, and since the close of the war he was responsible for the publication of the valuable statistical supplement to the report of the Nitrogen Products Committee. On the completion of his services to the Government he established a private practice as consultant. Those who attended the meetings of the Royal Institution, the Faraday Society and the Royal Society of Arts when questions relating to nitrogen were discussed will have reason to remember Dr. Harker's excellent contributions to the discussions and the readiness and clarity with which he spoke. Dr. Harker was engaged in interesting research work, and was, at the time of his death, a partner in the firm of J. F. Crowley and Partners, consulting chemists. His advice on important questions of physics and chemistry, especially on the manufacturing scale, was greatly esteemed. The loss of his charming personality will be widely felt in many circles.

Oct. 27.	BRITISH ASSOCIATION OF CHEMISTS. Sixth Annual Meeting, to be held at the Chemical Dept., Birmingham University, Bournbrook, 3 p.m.
Nov. 1.	SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, The Chemical Department, The University, Woodland Road, Bristol, at 7.30 p.m. "Some Aspects of the Paint Trade—Fine Colour and Lake Making." by A. H. Bridges.

OFFICIAL NOTICES

ROTHAMSTED LIBRARY

By the courtesy of the Lawes Agricultural Trust, any member of the Society of Chemical Industry on presenting a card from the General Secretary shall be allowed access to this Library. The rules of the Library preclude journals and periodicals from being sent out, and these are therefore always accessible.

A catalogue of the journals and periodicals is in the Society's Offices, at Central House, and may be consulted there by members.

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS,

October 31, 1923

This Dinner is being arranged under the joint auspices of the Chemical Society, the Institute of Chemistry, and the Society of Chemical Industry, and will be held in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Wednesday, October 31, at 7 for 7.30 p.m. The arrangements are being made by a Committee consisting of representatives of the Societies mentioned, and of one or two other Societies.

Sir William J. Pope, K.B.E., F.R.S., will take the chair. There will be some speeches and some music as well as opportunities for social intercourse.

No similar dinner for chemists has hitherto been organised on exactly the same lines, and it is expected that the gathering will be not only very pleasant, but will be useful in promoting that social acquaintance which is so valuable in connexion with prevailing ideas and hopes.

Members of any of the Societies concerned are invited to attend and bring guests. The price of tickets for ladies and gentlemen is 12s. 6d. each, not including wine. Applications for tickets (accompanied by the appropriate remittance) should be sent to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2, as soon as possible.

Applicants are invited to state names of any friends beside whom they wish to be seated, and the names of guests should be furnished at the same time.

SOUTH WALES SECTION

The first meeting of the Session in South Wales took place in Cardiff on October 12 with Mr. W. R. Bird in the chair. A discussion was held on the smoke problem. Mr. H. J. Bailey, F.I.C., opened the subject with a survey of the rise of the smoke nuisance in the thirteenth century when coal was first burned in London. In the reign of Edward the First a Royal Proclamation was issued forbidding the burning of coal while Parliament was sitting, but the air thus cleared for the legislators did not enable them to think of any efficient mode of dealing with the difficulty.

Smoke was the subject of a Royal Commission in 1819, and again in 1845, but the only tangible result seems to have been the finding of the fact that smoke is a nuisance. The Sheffield conference in 1909 was a real step in the right direction. Since then the problem has received serious and skilled scientific attention, and one of the results is that a smoke abatement bill is now before Parliament.

It is open to question whether the private houses or factories contribute the more to the nuisance. In most districts modern types of furnaces are employed mainly, and the contribution of such is much less than that of the domestic fire. This supposition is borne out by the Meteorological Office observations during the period of the sudden coal strike of 1921, when nearly all factories closed down at once, whereas domestic fires were in the main unaffected.

Passing to the consideration of possible remedies for the nuisance and its enormous waste, it was suggested that the only real solution lies in the increasing use of gas for domestic heating and of low-temperature briquettes. The use of powdered fuel in furnaces largely obviates the emission of smoke, but there remains the difficulty of the dust from the ash of the fuel.

Mr. Bird, as the result of long observation in Manchester, considered that the domestic hearth creates much the greater nuisance. With regard to the industrial furnaces, he laid stress on the superiority of the water-tube boiler over the older Lancashire type. In New York only anthracite, which is practically smokeless, is allowed to be burned.

Mr. T. G. Watts referred to the economy resulting from the use of gas, coke and low-temperature briquettes, which latter can now be obtained sufficiently hard to withstand the effect of transport. Mr. H. W. Webb drew attention to the fact that a certain amount of distillation necessarily results from any form of top-feed stoker. No arches in the furnace can altogether eliminate waste and smoke resulting from such distillation. Under-feed stokers are the only kind which are scientifically correct.

It has been arranged to hold a dinner of the Section on the occasion of the President's visit on November 8 next. Also members of the Section will visit the Maritime Coke Works, Pontypridd, on Thursday, December 13.

CERAMIC SOCIETY

The autumn meeting of the Refractory Materials Section was held in Chester on October 4 and 5, the president (Mr. J. Holland) presiding over a large attendance. Brief notes are here given of the papers read.

(1) Mr. T. Acton gave a general sketch of the geology of the Chester district—including adjacent parts of North Wales—which was illustrated by lantern slides, maps, sections, diagrams and specimens of rocks and minerals.

(2) " Improvements in Drying Refractories or Other Goods," by J. Holland and W. J. Gardner. This relates to a tunnel dryer with travelling racks, the one specially described having a hot zone 60 ft. long and 3 ft. wide, with a longitudinal flue beneath, heated by

means of a furnace or by the heat from waste gases. The flue communicates with two longitudinal lateral flues, one on each side which lead to the chimney stack over the front end of the dryer. Continuous with the hot zone is a cooling chamber 10 ft. long. Two parallel steel tracks containing steel rollers extend the whole length from feeding end to delivery end of the dryer. As compared with hot-floor drying it is claimed that with this system conditions for workers are better and the goods are of higher quality. Much time is saved, and a very much smaller area is required for a given output of silica bricks or other goods. The stove of two chambers described can dry 5000 bricks per shift of 9 hours, using 4 cwt. of coal.

(3) " The Zenith Temperature," by Dr. J. W. Mellor. According to the kinetic theory of gases, temperature is determined by molecular or atomic movements, and their mean velocity V at the absolute temperature T is $V=15800\sqrt{T/M}$ cm. per sec. If the postulate of the quantum radiation theory is right, and the velocity of light (about 3×10^{-10} cm. per sec. in vacuo) is the maximum speed at which material things can travel, then for hydrogen the lightest gas, $M=1$, and therefore $3\times10^{-10}=1{\cdot}58\times10^{-4}\sqrt{T}$. Accordingly, if everything varies continuously on a rising temperature, the zenith temperature must fall short of four billion degrees C.

(4) " Notes on the Proctor Dryer," by A. H. Middleton. The Proctor dryer is essentially a close heated chamber, the atmosphere of which is dry at one end and very humid at the other. The wet goods are thoroughly heated to their core in a very humid atmosphere before any surface drying can take place. The machine at Consett is a three-track tunnel dryer consisting of a rectangular chamber 50 ft. long, 20 ft. wide and 6½ ft. high, holding 8 cars on each of the three tracks, and having a total capacity of 14,976 bricks. If bricks alone were being dried, the drying could be completed in 12 hours, and probably in 8 hours. Economical results can be obtained by working the different tracks on different schedules for different classes of goods, though of course the best results would attend the drying of one class of goods at a time. Advantages claimed for the Proctor dryer, as compared with hot floor, are that drying—especially of difficult shapes—can be carried out much more quickly and with less risk of cracking and setting up drying strains, that the conditions in the moulding shop can be made much healthier and pleasanter for the workers and that a large saving in fuel can be made, excepting when heat for drying can be provided from exhaust steam or some source that could not otherwise be utilised.

(5) " New Methods of Producing Gas for Industrial Operations," by R. Maclaurin. The three different chemical reactions utilised in making industrial gas are discussed at considerable length, viz., the distillation reaction, the reaction of air with large excess of heated carbon (producer gas reaction), and the water-gas reaction. In the Mond and Maclaurin producers, combinations of these reactions take place. A description was then given of the Maclaurin producer at Grangemouth. When full the plant holds about 30 tons of coal and working is continuous, about a ton of coal being put in at the top every hour and the equivalent in coke or residue withdrawn from the bottom. To change over from working for coke to working for complete gasification, it is necessary to adjust the valves controlling the air blast and the withdrawal of the gas respectively; by these adjustments either a black smokeless fuel or a hard grey coke or an ashy residue can be obtained. Several hundred tons of the coke have been used in blast-furnaces in Scotland. The yield of oil varies up to 30 or 40 galls. per ton, the average yield from bituminous coals lying between 14–20 galls. per ton; the oil has found use for the manufacture of resins, lacquers, lubricating and fuels oils. The ammoniacal liquors differ from ordinary gas works and coke-oven liquor in being free from ferrocyanides and sulphocyanides, and in containing polyhydric phenols, one of which gives a quinoneoxime somewhat similar to resorcinol green, this product being the first dye to be taken direct from ammoniacal liquors. A brown pigment and other coloured products are also obtained. The ammonia can be obtained as white sulphate by the ordinary methods, the yield ranging from 16 to 80 pounds. The author adduced figures to show that his plant could be advantageously applied in drying ceramic wares or bricks, as the gas could be produced at less than 1d. per therm. The great distinguishing feature of this gas is the relatively very large percentage (13) of methane, which enables flames of considerable length to be provided. The advantage of using the gas for power is urged, the cost per horse-power-hour being estimated at one-ninth of a penny.

(6) " The Effect of Salty Coal upon Refractory Materials," by L. M. Wilson, M.Sc. The author investigated the action of ammonium chloride, which is found in coke-oven gas from salty coal, and concluded that: (1) There is a critical temperature at about 900° C., at which the chemical properties of burned fireclay seem to undergo a change, quite apart from the critical temperatures at which the physical properties of either raw or fired materials are known to alter. Below this temperature very little alumina is removed, and above it a great deal of alumina is removed by the action of heated ammonium chloride. (2) The experimental evidence demonstrated the superiority of high-grade silica over fireclay for the lining of coke ovens as regards resistance to salty coal. (3) At temperatures from 700° C.

to 1200° C. and higher, ammonium chloride removes iron and alumina from fireclay and from silica bricks.

(7) "Carbonisation of Clay," by W. Smith. By saturating clay, at a certain stage of heating (when the clay has maximum porosity) with hydrocarbon gases or volatile hydrocarbons under pressure, finely divided carbon is deposited on all the particles of the clay. The biscuit clay so carbonised is black even when very finely divided. Subsequent heating produces the usual contraction of the clay, the carbon particles being enclosed under great pressure, forming a composite body of great density and hardness. By firing this product in a strongly oxidising flame, it is converted into a microscopically porous structure by the burning away of the carbon, the refractory properties being improved. For the black carbonised clay, the term "carbonite" is suggested for industrial purposes. Its hardness and toughness adapt it for abrasives, for mixing with cement, for road-making, etc. It is very refractory to heat in the absence of air, is resistant to acids, and impervious to weather or atmospheric action. The white carbonised clay or "carbo-calcined" clay, because of its artificially produced porosity, has good refractory properties. The durability of "carbo-calcined" bricks in industrial furnaces has been proved to be superior to that of articles produced from the natural clay. The binding of carbonised clay is accomplished by pressure, just as with magnesite. Artificial binders should be used sparingly. Carbonisation increases the normal formation of sillimanite in aluminium silicates.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held at the Offices of the Association on Thursday, October 11, 1923, Sir Max Muspratt, Bart., presiding.

The General Manager stated he had become a member of the Committee set up by the London Chamber of Commerce to correlate evidence to be given on behalf of the manufacturers and users in connexion with the use of preservatives and colouring matters in food. Mr. E. J. Boake will give evidence early next month on behalf of the makers of Sulphites.

The first film dealing with the chemical industry will shortly be ready for exhibition to the public. This deals with the Coal Tar section, and later a film dealing with Heavy Chemicals will be available.

The question of contracts with local authorities, etc., was again considered, and members are being asked for further information to enable the matter to be carried to a definite conclusion.

In connexion with the visit of the Colonial Premiers to this country it was agreed to bring the chemical industry before their notice and, if time permits, they will be asked to visit certain representative works.

A report from the General Manager on the working of the Dyestuffs Act revealed that there was an increase in the quantities of German dyestuffs imported into this country during the first six months of 1923, as compared with the corresponding period of last year, but this was largely due to the collapsed exchange. It is interesting to note that conversations are at present taking place between the makers and the users in an attempt to arrive at a stabilisation of prices.

The arrangements for the Chemical Section of the British Empire Exhibition are progressing satisfactorily. The exhibitors themselves have agreed to a comprehensive scheme of lay-out and decoration which will naturally serve to make the Chemical Exhibit more attractive. The editors of the Technical Press have undertaken to assist in every way in giving full prominence to the exhibition in their journals and elsewhere.

The Scientific Section promises to be one of the most pleasing parts of the exhibition. A very comprehensive classification of exhibits has been arranged, and some of the most eminent scientists have undertaken to be responsible for the work in the various sections.

The question of awards was considered, and having regard to all the circumstances the Council were of the opinion that the best way of dealing with the matter was to do away with the usual system, and in its place adopt a commemorative medal which could be given to all exhibitors. It was agreed to place this view before the exhibition authorities.

The Council authorised an objection being lodged with the Railway Rates Tribunal against the schedules of standard charges, as proposed by the railway companies.

ACADÉMIE DES SCIENCES

During the meeting held on October 8, Prof. Perrin utilised the phenomenon of fluorescence to explain the radio-chemical theory and show that temperature influenced, though but feebly, photochemical radiations.

Prof. Sabatier discussed the decomposition of calcium carbide and metallic salts in aqueous solution. In the presence of cupric chloride, cupric acetylide, insoluble under certain conditions, was obtained at the same time as acetylene. By means of this method a number of new acetylides were obtained.

* * *

Dr. J. Brand, who recently retired from the chair of pharmacology and pharmacy, in the University of Munich, has been succeeded by Dr. A. Joelbauer.

THE BRITISH EMPIRE EXHIBITION (1924)

The Editors of the various technical journals met Mr. Woolcock, the General Manager of the Association of British Chemical Manufacturers, at the offices of the Association, to discuss with him the progress which has been made with the preparation of the Chemical Section of the British Empire Exhibition. In the course of the conversation Mr. Woolcock said :—

"The Chemical Section which is being organised by the Association and occupies nearly 40,000 sq. ft. in the Palace of Industry will be built in such a way as to form a Hall within the Palace. About £100,000 will be spent in presenting to the public a picture of the present state of British chemical industry. No important firm in the industry will be unrepresented, and the whole of the individual exhibits, numbering about one hundred, will, by reason of their position and character, combine to form a magnificent illustration of the industry. It has not, however, been considered sufficient that we should merely show visitors examples of the products of the industry. The best possible exhibition of this kind would leave one question unanswered. The visitor may be satisfied that he is witnessing a demonstration of the position which the industry has attained, but what the critical person who examines the exhibit requires to know is whether there is behind this example of what has been achieved a scientific basis which will ensure the continuance of this progress. For this reason in the centre of the Chemical Hall there is to be illustrated the progress which has been made in pure chemistry during the past twenty or thirty years, with a view to showing that the stream of scientific invention in this country is still flowing steadily onwards."

The Scientific Section is being organised by a Committee consisting of representatives of the following bodies : The Chemical Society, the Society of Chemical Industry, the Institute of Chemistry, the Society of Dyers and Colourists, the Pharmaceutical Society, the Institution of Petroleum Technologists, the Institution of Chemical Engineers. The Committee is working in close co-operation with the Royal Society. In order that both the general public and scientific persons may have a record of the exhibits, it is proposed to publish a number of pamphlets, specially written for the purpose, dealing in popular language with the various classes of exhibits in the Scientific Section. In addition to this, it is proposed to publish in more technical language a work which will not only explain the scientific exhibits, but which will put on record in a very complete form the state of our knowledge in chemical matters at the date of the Exhibition.

The Editors present agreed to give any assistance in their power in organising the publicity service of the Chemistry Section.

A meeting of the Exhibitors was held in the Chemical Hall at Wembley on the 16th inst. ; we hope to publish shortly a complete list of the firms exhibiting.

The organisation of the Chemical Section is entrusted to various committees, the Executive Committee, of which Mr. Woolcock is chairman ; the Publication Committee, of which Dr. E. F. Armstrong is chairman ; and the Scientific Committee, of which Dr. H. Levinstein is chairman.

CORRESPONDENCE

THE DETERGENT ACTION OF SOAP

Sir,—In reply to "Raybell's" letter which appeared in your issue of October 5, concerning the purity of the materials used in investigating detergent action, I should like to point out that a paper published by Laing and McBain (*Trans. Chem. Soc.*, **117**, 1507) contains a full account of the degree of purity of various specimens of Kahlbaum's oleic acid which have been used in this laboratory. The potassium oleate used in detergent action, however, was not made up by us from oleic acid and potassium hydroxide, but was supplied as such by Kahlbaum's and was the purest obtainable. As was pointed out in the published paper, this potassium oleate was found to be 3 per cent. acid.

Myristic acid of undoubted purity (giving theoretical molecular weight and melting point, etc.) was used in the preparation of solutions of potassium myristate.—I am, Sir, etc.,

A. Millicent King

Department of Physical Chemistry,
University of Bristol

THE CHEMICAL ENGINEER

Sir,—The correspondence in your columns on the chemical engineer recalled the very valuable discussion held by the Faraday Society in 1917, and published in Vol. XIII. of its *Transactions*. In this many representatives of chemistry and engineering took part, and the whole discussion is well worth serious study by those who are interested. For my own part, I believe the right note was struck by Prof. Donnan in his statement that "the only road to real applied chemistry lies through a close and thorough study of physical chemistry." Mr. Greenfield, in your last issue, would have us think that a real chemical engineer is a "physical engineer," and his contention certainly has in it a good deal of truth. It is, however, too narrow. He should have said a "physico-chemical engineer," because there are many things, such as chemical equilibria, which enter into the problem, which we cannot fairly expect the physicist to have studied in such detail as the chemist. The study of

thermodynamics, chemical equilibrium, electrochemistry, the phase rule, colloid chemistry and the like is, in my opinion, an essential part of the training of the chemical engineer, and I think your readers would find in Professor Donnan's article a key to some of their difficulties. The actual "works sense" can probably only be acquired on the works, but with good will and the co-operation of the men of experience, the young chemist trained on the above lines would, I think, soon prove his value. I have no wish to dogmatise in a region outside my own activity, but I think some purpose may be served in calling attention to what has already been said on the matter.—I am, Sir, etc., J. R. PARTINGTON.
East London College, University of London.

NEWS AND NOTES

FRANCE

The Eighth Congress of Fisheries and Maritime Industries

The Eighth Congress held at Boulogne, from September 9 to 16, was extremely successful and well attended, a large English delegation being present, and the British Oceanographic Research Ship being available for inspection. Numerous papers were read, including "The Utilisation of Squalids," by Dr. Ehrenreich; "The Production of Fish Oils," by Monsieur E. André; "The Utilisation of Fish Scales," by Monsieur Dollfus; "The Life of the Eel,' by Prof. Joubin; numerous visits were made to factories and there were many excursions. One paper, on "The Origin of Artificial Pearls," by Monsieur Pohl, was of particular interest, as it traced the history of the manufacture of artificial pearls from early Chinese times when the silvery pigment from the bodies of certain fish was utilised. In 1860, the Frenchman Jacquin utilised the same material to manufacture the first artificial pearls in Paris. At first the scales employed were obtained from the "ablet": the organic matter is removed leaving a silvery pigment, which is preserved in ammoniacal solution. The solution is gradually dehydrated and is finally mixed in a plastic mass of cellulose ethers to be applied to a support. As only 500 g. of crude scales can be obtained from 2000 ablets, the industry could hardly be extended, though scales of various fish are also used, particularly those of the herring, scales of which were produced in the United States in 1921 to the value of $15,000.

Developments of Coking Installations

In a recent issue (*Chem. and Ind.*, 1923, 915) we referred to the erections of new batteries of coke ovens by an important iron and steel company in France. It is now reported that the Hauts Fourneaux et Fonderies de Pont à Mousson are to reconstruct their plant, and the Société de Chatillon Commentry et Neuves Maisons is to erect coke-ovens at Neuves Maisons, where its principal metallurgical works is situated. In Lorraine two new batteries are being erected at Moyeuvre by the Wendel Co., which is also considering the construction of one or two batteries at its Haynge Works. The Société Lorraine is also to erect a battery and similar projects are to be considered at Knutange, Hagondange and Rombas. These recent decisions are facilitated by recent studies carried out in the Saar District and in Lorraine on the production of coke (*cf. Chem. and Ind.*, 1923, 278). It is interesting to note that the Strasburg Gas Co. has formed a company under the name of "Alcok," with the object of building batteries of coke-ovens in the neighbourhood of Strasburg. The Société Minière and Metallurgique is now taking a new battery through a trial run. This particular battery is fitted with the high narrow ovens which recently gave such promising results.

Fuels

The decision of the Belgian Government to reduce by 50 per cent. exports of Belgian coal after October 1, has caused considerable discussion in France. The restriction is based on the quantities exported between August 20 and September 19. The reduction, however, will not be applied to the industrial coal from the Mons basin, or to briquettes. The importance of this decision is shown by the fact that France imports at least 100,000 tons of Belgian fuel per month, and is moreover the traditional customer of the Charleroi basin. The coal market in France is active and the improvement in the Ruhr situation is being followed with the closest attention.

CANADA

The Paper and Pulp Industry in 1922

The Canadian pulp and paper industry has made a satisfactory recovery from the unfavourable conditions which prevailed in recent years. The total net value of production was $236,420,176 in 1920, but during the period of reconstruction in 1921, the value fell to $151,003,165. The total of $155,785,388 for 1922, however, shows a tendency towards normal progress. In the year under review 104 pulp and paper mills were in operation (100 in 1921), 43 manufacturing pulp only, and 33 paper only, 28 being combined pulp and paper mills. The total output of pulp was 2,150,251 tons, valued at $84,947,598, an increase of 38·8 per cent. in quantity over 1921. Exports of pulp in 1922 were 818,247 t. ($41,037,849), as compared with 527,222 t. ($33,133,675) in 1921. During the same periods the imports of pulp amounted to 17,300 t., valued at $1,008,527, and 17,354 t., valued at $1,683,041, respectively. The total output of paper amounted to 1,366,815 t., together with certain miscellaneous pulp products valued at $107,085,766, an increase of 34·1 per cent. in quantity over 1921. In 1922 this output of newsprint paper amounted to 1,081,364 t., approximately 80 per cent. of the Canadian paper output, valued at $75,971,327. It is anticipated that Canada's newsprint output will exceed that of the United States during 1923 or 1924, thus making Canada the world's largest producer of newsprint paper. Exports of newsprint paper in 1922 amounted to 959,514 t., valued at $68,362,817.

The total number of employees in the industry in 1922 was 25,830, the total of wages and salaries amounting to $32,918,955 ; the capital invested has increased from $379,812,751 in 1921 to $381,006,324 in 1922.

Silica

The valuable series of monographs issued by the Mines Branch, Canada, Department of Mines, on the mineral resources of Canada has been enlarged by the recent publication of one entitled "Silica in Canada, its Occurrence, Exploitation and Uses" (No. 555, pp. 126) by L. H. Cole, Part I., now issued, is devoted to Eastern Canada and describes the nature and features of the various deposits of commercial silica. In addition to an interesting chapter on industrial uses, the results of laboratory tests are given and the brochure concludes with an illustrated description of methods of proving and working silica deposits. At present a large part of the higher grades of industrial silica used in Canada is imported from the United States, Great Britain and Belgium, but the Mines Branch has now shown that many deposits in Eastern Canada should, if properly operated, yield material equal to that imported.

GENERAL

World's Beet Sugar Production

The following table has been compiled, showing the area under sugar beet and the production of the roots in 1921 and 1922 in various countries :—

Country	Area (1000 acres)		Production (1000 metric tons)	
	1922	1921	1922	1921
Germany ..	1129	1086	10,791·6	7979·8
Belgium ..	148	143	1695·4	1462·9
Bulgaria ..	25	20	213·8	173·4
Denmark ..	60	88	573·0	868·6
England and Wales ..	8	8	—	—
Finland ..	2	2	11·5	13·0
France.. ..	286	298	2873·3	2060·6
Italy	222	158	2260·0	1751·3
Netherlands ..	143	183	1846·2	2708·3
Austria ..	27	20	176·7	93·8
Poland.. ..	269	196	2671·4	1128·8
Rumania ..	54	57	—	351·6
Sweden ..	41	121	456·5	1484·6
Switzerland ..	2	2	34·0	42·4
Jugoslavia ..	49	41	—	188·5
Spain	110	133	—	1816·4
Czechoslovakia.	519	544	5240·1	4071·7
Hungary ..	90	103	573·4	542·9
Canada ..	20	30	156·9	243·1
United States..	535	810	4744·6	6965·3

It will be noticed that most European countries increased their output of sugar beet in 1922, even where a decrease in the acreage is shown.

REVIEWS

Chemistry ; Inorganic and Organic, with Experiments. *By* Charles Loudon Bloxam. *Eleventh edition, edited by A. G. Bloxam, F.I.C., and S. Judd Lewis, D.Sc., F.I.C. Pp. ix+832. London : J. and A. Churchill,* 1923. *Price* 36*s*.

No one could be surprised if, after thirty-seven years from the date of its first issue, Bloxam's *Chemistry* could be shown to have lost some of its importance as a standard work, and there can be little doubt that a publication of this type must appeal to a class of reader which becomes more and more restricted as each successive edition appears.

Anyone desiring to acquire a passing acquaintance with a chemical subject, however, might do worse than to consult this work, for they will then find information which will be sufficient for many purposes, or at least prepare them for more adequate treatises.

That the book has not been thoroughly modernised is a fact obvious at first sight. It is hardly necessary to do more than make the following quotations :—"Such a substitution of chlorine for hydrogen accompanied by the simultaneous formation of hydrochloric acid is known as metalepsis, and is a very common reaction of chlorine with hydrocarbons ; since the formation of hydrogen chloride is initiated by light it is not surprising that metalepsis is aided by this agency." (Page 103.) "Its powerful action on bases places nitric acid among the strongest acids, though the disposition of its elements to assume the gaseous state at high temperatures, conjoined with the feeble attraction existing between nitrogen and oxygen, causes its salts to be decomposed, without exception, by heat." (Page 187.) "Nitrous acid may be regarded as a solution of NO and NO_2 in water ($H_2O.N_2O_3$ or $H_2O.NO.NO_2$). The former tends to combine with oxygen to form NO_2, and the latter tends to part with oxygen to form NO, so that nitrous acid can behave, according to circumstance, either as a reducing agent or an oxidising agent. Obviously any compound capable of parting with oxygen to NO cannot obtain oxygen in the same circumstances from NO_2." (Page 194.) It is obvious that no addition of footnotes will ever reconcile these statements with our present knowledge, and it is to be regretted that the editors went so far as to allow what is to all intents and purposes incorrect to persist in the eleventh edition.

After discussion on some fundamental principles in an introduction, the nature and properties of water are dealt with, together with a few words about hydrogen and oxygen. In this connexion it is noteworthy that no mention is made of permutit as a water softener. We are then given in connexion with air the properties of nitrogen and oxygen and also carbon dioxide, whilst more about hydrogen forms the fourth chapter. We have to wait till the sixth and seventh chapters to arrive at the properties of the compounds of oxygen and nitrogen respectively. In the eighth chapter part of the fourth group is dealt with, and carbon dioxide, having been dealt with under the heading of air, is omitted. Then after the inert gases come the general principles and physical chemistry. In the latter part of the book metallic elements are considered in a more or less normal way, the only peculiarity being that glass and niton (not the ultimate state of matter as stated) are included with the alkaline earths.

The organic section is dealt with on lines similarly unique, and the advantage of considering the paraffins, ethylenes, acetylenes, benzene, naphthalene, anthracene, phenanthene and fluorene in succession merely because they happen to be hydrocarbons is no more apparent than that of dealing with them in the order of their carbon content. However, it is admittedly a matter of opinion as to whether or not the arrangement adopted gives on the whole a balance of advantages, and the only serious criticism that can be made is the failure on the part of the editors to modernise isolated statements so out of date as to have become practically untrue, since this is apt to undermine the confidence of any class of reader with regard to the trustworthy character of the book.

G. N. White

Kolloide in der Technik. *By* Dr. R. E. Liesegang. *Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe edited by* Dr. R. E. Liesegang. *Pp.* 157. *Dresden and Leipzig: Theodor Steinkopff*, 1923. *Price* 3*s.* 6*d.*

In choosing "The World of Neglected Dimensions" as the title for his introduction to colloid chemistry, Wo. Ostwald displayed a sense of humour not unmixed with subtle irony, that will be readily appreciated by colloid chemists when they attempt a survey of the literature of their subject. To them will come this new volume of R. E. Liesegang as a boon and a blessing, or at least as an aid in coping with the neglected dimensions of the literature of their subject. As a survey of the field of colloid chemistry in technology the book will be welcomed, as it deserves to be, as a careful review of the progress made during the last few years. In the compiling of such a work there will always be the difficulty of adequately linking up so heterogeneous a mass of detail, without, on the one hand producing a mere catalogue of literature, or on the other an unwieldy volume. Dr. Liesegang has succeeded admirably in this task. In the fourteen chapters of his book he has provided the best short summary of the subject extant. Commencing with glue and gelatin and other adhesives, he next reviews recent work on protective colloids, plastic masses, tanning. soap, oils, resins, rubber, textiles and dyeing. metals, ceramics, foodstuffs, and concludes with a chapter on photography and reproduction technics. All this in the space of 147 pages.

It will be appreciated that the book is not designed for the general reader but for the worker in one or other branch of colloid chemistry, or more especially for the technologist whose subject involves the application of the principles of colloid chemistry, and to such its value will not be lessened by the fact that the greater number of literature references are to papers published since 1918.

To merely look for and catalogue omissions in such a book as this were a graceless task. The value of Dr. Liesegang's work is such that further editions are certain to be called for, and when that time comes the author will be enhancing the benefit he has conferred on colloid chemists by including, as he doubtless will, some further details of electro-endosmose, and in particular its application in the ceramic and metallurgical industries. Attention might also be drawn to the colloidal theory of corrosion and to the important applications of the study of disperse systems in gases.

Despite minor imperfections and omissions, the book can be confidently recommended as an exceedingly able and informing review of the applications of colloid chemistry to industry, and as such worthy of a place on the bookshelf of every colloid chemist.

H. W. Greenwood

A Handbook on Rubber Uses and Their Development. *Pp.* 162. *London: The Rubber Growers' Association, Inc.*, 1923. *Price* 2*s.* 6*d.*

In 1919 the Rubber Growers' Association organised a competition with the object of discovering new uses for rubber and thereby increasing the consumption. About 10,000 suggestions were received, and were examined by a board of adjudicators from the standpoints of practicability in manufacture, suitability of cost and ease of exploitation. A selection of the most promising suggestions has now been published in the book under review, which is divided into sections devoted, respectively, to moulded articles, open-heated goods, sheet rubber, proofed material, dipped goods and footwear. etc., sponge rubber and tyres, vulcanite and miscellaneous articles. It is impossible to review such a wide variety of suggested uses, which, to be of value, must be attractive both to the manufacturer and to the consumer, and, moreover, still await trial. The book makes interesting reading. and should stimulate interest in the already very varied uses of rubber. An appropriate note is provided by the use of rubber-latex paper for the book.

REPORTS

Report on the Economic, Financial and Industrial Conditions of Finland. Dated March, 1923. *By* C. H. Mackie, *H.M. Consul, Helsingfors. Department of Overseas Trade. Pp.* 64. *H.M. Stationery Office*, 1923. *Price* 2*s*.

In 1922, Finnish trade with foreign States began to develop. As a result of a large surplus of exports over imports much foreign currency entered the country and the value of the Finnish mark rose steadily. Further improvements in the economic condition of the country must depend largely on the progress of neighbouring States.

Industries have made rapid progress since the war, the number of factories having increased from 2582 in 1914 to 3138 in 1921. The glass industry made progress during 1922, the output being valued at 45 million F.mks. compared with 33·7 million F.mks. in 1921. Exports, though of less bulk, were of greater value, owing to the larger proportion of table glass and crystal. The Portland cement factories have a manufacturing capacity of about 1,000,000 barrels per annum, which leaves a margin for export. The sugar industry is in the hands of the Finnish Sugar Co.; output increased from 25,800 t. of refined sugar in 1921 to 33,700 t. in 1922. Large quantities are still imported. The year opened badly for the iron and steel trade, but as German prices rose the position of Finnish manufacturers improved and with an import tariff they are now in a much better position. No important developments have taken place in the pulp and paper industry, though the introduction of new methods has increased productive capacity. A new Government factory for the production of sulphuric acid was opened in August, 1922, capable of producing 9000 t. of 93 per cent. acid annually. A State-owned superphosphate factory has also been erected.

The trade balance in 1922 was favourable for the first time, exports amounting to 4461 million F.mks. and imports to 3953 mill. F.mks., compared with 3389 mill. F. mks. and 3585 mill. F.mks., respectively, in 1921. Great Britain, taking 37 per cent. of the exports was by far Finland's largest customer, France coming next. Germany led as a source of imports, though Great Britain improved her 1921 proportion; it is pointed out, too, that German competition is declining. Among the principal imports in 1922 were iron and manufactures, 81,000 t.; lead, 353 t.; tin, 152 t.; copper, 370 t.; phosphates and bone meal, 20,000 t.; saltpetre (Chile and Norwegian), 3788 t.; potash salts, 11,637 t.; basic slag, 14,539 t.; superphosphates, 11,617 t.; white lead, zinc white, etc., 1688 t.; aniline dyes, 391 t.; sulphur, 27,220 t.; caustic soda, 1575 t.; common salt, 76,660 t.; calcium chloride, 3423 t.; Glauber's salt, 19,125 t.; alum and aluminium sulphate, 4451 t.; soda, 3156 t.; oils, resins, wax, rubber, etc., 11,573 t.; mineral oils, 38,702 t.; cement, 3961 t.; coal, anthracite, coke, 243,097 t.

Report on the Economic Situation of Denmark, to March, 1923. *By* R. M. Turner, *H.M. Commercial Secretary, Copenhagen. Department of Overseas Trade. Pp.* 48. *H.M. Stationery Office*, 1923. *Price* 1*s*. 6*d*.

The year under review was characterised by general financial reconstruction (*cf. J.*, 1922, 405 R), and many concerns had to face considerable losses. The sacrifice, however, has had its desired result and general business conditions in Denmark have shown an improvement, though this is due in some measure to the general improvement throughout the world. The tendency seems to be persistent, though the dependence of such a small state on its foreign neighbours is an important consideration. Although wages have been reduced an increased number of workers is employed, making manufacturing costs excessive. The iron and steel industry suffered in 1922 owing to the quietness of the ship-building yards; the severe German competition of 1921 seems to be decreasing. The soda factories suffered delays in obtaining supplies of chemicals; prices have been lowered by competition and profits further reduced by the rise in sterling exchange. The largest firm making artificial manures was reconstructed in 1922, and managed to show a profit on the year's working, which will be used partly in covering the debts carried on from the old company. There was an improvement in the paper-making industry, imports of pulp being considerably increased. In 1922 the harvest, contrary to earlier expectations of a partial failure, was about normal. The sugar crop only amounted to 90,000 t., compared with 130,000 t. the previous year, and this will be insufficient to meet home demands in 1923.

Although the total value of imports during 1922 was less than in 1921, 1505 mill. Kr., against 1640 mill. Kr., their actual bulk was greater, the same being noticeable with exports, 1242 mill. Kr. against 1511 mill. Kr. As in previous years the chief customer was Great Britain, though details are not available. The value of goods imported from Great Britain seems to show an increase over the 1921 figure. Among the articles of trade during 1922, with their values in millions of Kroner, are skins, hides, etc., and manufactures, imports 41, exports 28; tallow, rubber, etc., and manufactures, imports 94, exports 28; chemicals, imports 24, exports 6; fertilisers, imports 44; mineral fuels, imports 125; raw or roughly worked minerals, imports 16, exports 20; iron and manufactures, imports 106, exports 15; other metals and manufactures, imports 33, exports 6.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Oct.* 11)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Electrical accessories, artificial silk	379, 380
British India	Hardware	381
,,	Oil-tank wagons, white lead, iron and steel (tender)	*
Canada ..	Surgical and medical appliances, drugs	384
,, ..	Centrifugal sewage pump (tender)	12199/E.P./E.C./2
Dominican Republic	Hardware, crockery ..	8660/F.L./G.C./A.2
Egypt ..	Paper (tender) ..	11614/F.E./M.P.
Finland ..	Saccharin, isinglass ..	394
Italy.. ..	Chemicals, fertilisers, oils	397
New Zealand	Patent medicines, drugs, photographic materials	389
Norway ..	Leather; asbestos, rubber goods, aluminium foil	398, 399
South Africa	Linseed oil (tender) ..	12290/E.D./C.C./2/A
,,	Machine oil (tender) ..	12290/E.D./C.C./2 (B)
,,	Antifriction grease (tender)	12290/E.D./C.C./2/C
,,	Buffalo hides (tender)	12339/E.D./M.P.
Spain ..	Dental specialities, druggists' supplies	400
,, ..	Porcelain, crystal, leather	401
Spain—Canary Is.	Building materials, iron and steel, cement, asbestos cement	404
Madeira ..	Tinplate, cement ..	405

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1.

TARIFF CUSTOMS EXCISE

Germany.—The internal tax on sugar has been increased. Ammonium nitrate, paper, and articles of platinum, gold and silver are exempted from export licences.

Greece.—The current issue contains particulars regarding the importation, preparation and sale of quinine.

Mexico.—Imports of opium, cocaine, heroin and morphine are prohibited.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains the improvement recently recorded and trade seems now to be more settled. No price changes have occurred, the slight variations which may have been noted from time to time being purely of a temporary character. Foreign materials are still being offered, but in general prices are comparable with those quoted by home manufacturers.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric ..	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw. ..	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali ..	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder ..	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride ..	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate ..	5¾d.—6d. per lb. d/d.
Potass. Chlorate ..	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24–£25 per ton. Still scarce for spot delivery.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.

Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£16 10s.–£17 per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Business in this section is generally on the dull side.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide ..	5s. 9d. per lb.
Carbon Bisulphide ..	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide ..	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark ..	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite ..	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor..	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. Slightly weaker.
Brown Sugar of Lead ..	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Good demand. Market firmer. Limited quantities only available for prompt delivery.
Crude 60's	3s. 6d.—3s. 8d. per gall. Good demand for spot delivery. Supplies limited.
Acid Cresylic—97/99 ..	2s.—2s. 5d. per gall. Steady demand.
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 10d.—2s. per gall.
Anthracene Paste 40%..	4d. per unit per cwt. Nominal price. Few inquiries but no business.
Anthracene Oil—	
Strained	8½d.—11½d. per gall. Supply short. Fair demand.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor ..	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 6d.—1s. 8d. per gall. Little business passing.
Pure	1s. 10d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24% ..	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9½d. per gall. according to grade and district. Demand still good.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160 ..	1s. 1½d.—1s. 3d. per gall. Prospects brighter.
Solvent 90/190 ..	1s. 3d.—1s. 4½d. per gall.
Naphthalene Crude—	
Drained Creosote Salts	£7 10s.—£8 per ton. More inquiry. Difficult to meet demand.
Whizzed or hot pressed	£9 10s.—£11 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked..	£19 10s. per ton.
Pitch, medium soft ..	130s.—140s. per ton, according to district and time of delivery. Several inquiries. Market firm and price tending to advance.
Pyridine—90/140 ..	21s.—21s. 6d. per gall. Market very strong.
Heavy ..	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Improvement in dyestuffs business maintained. Prices show a slight hardening tendency.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%..	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic ..	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 7d.—1s. 8d. per lb. Good demand.
Acid Sulphanilic ..	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 3d. per lb.

p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C. ..	5½d.—6d. per lb. Prices slightly reduced and a better demand is experienced.
m-Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol ..	£85 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol ..	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine ..	1s. 6½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. per lb. 100% basis d/d.
Nitronaphthalene ..	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol .	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	4s. 6d. per lb. d/d.
p-Phenylene Diamine ..	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine ..	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Market more active and makers well employed. Prices gradually rising with steady tone in view of lack of foreign competition.

Acid, Acetic 80% B.P.. .	£52 10s. per ton.
Acid, Acetyl Salicylic ..	3s. 3d. per lb. Good demand. Firm market. Shortage not improbable.
Acid, Benzoic	2s. 6d. per lb. Higher prices quoted on the Continent.
Acid, Boric B.P. ..	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 6½d. per lb., less 5%. Poor demand. Market dominated by weak holders and bad season.
Acid, Gallic	3s. per lb. for pure crystal. Market steady.
Acid, Pyrogallic, Cryst.. .	5s. 9d.—6s. per lb., according to quantity.
Acid, Salicylic	2s. 3d.—2s. 5d. per lb. for 5 cwt. lots. Firm market. Prices advanced and makers heavily booked ahead.
Acid, Tannic	3s. per lb. for B.P. quality. Weaker in view of Continental supplies coming forward.
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Demand fair and likely to improve. Raw material dearer. Prices will probably advance.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d. per lb. for English manufacture. Shortage exists. Some holders asking 1s. 10d.
Amidopyrin	12s. 6d. per lb. Large inquiries from abroad are reported.
Ammon. Benzoate ..	3s.—3s. 6d. per lb., according to quantity.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make.
Barbitone	17s. per lb. for quantity. Price stiffening.
Benzonaphthol	4s. 9d. per lb.
Bismuth Salts	A steady market. Carbonate 13s., Nitrate 6s. 11d., Salicylate 10s. 5d., Subgallate 9s. 6d., Citrate 11s. 7d., Oxide 14s. 5d., Subchloride 12s. 8d., Subnitrate 11s.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.

Bromides—		
Potassium	6½d. per lb.	Holders of stock are steadying up prices owing to uncertain position of Continental supplies
Ammonium	7d. ,, ,,	
Sodium	7½d. ,, ,,	

Chloral Hydrate ..	4s. per lb. In active demand. English makers are oversold. A large Continental maker cannot supply.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Guaiacol Carbonate ..	10s. per lb. for spot. This is below Continental price.
Hexamine	4s. per lb. Very steady.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate ..	Reduced by 2d. per lb. 2s. 3d. per lb. for cwt. lots. 2s. 4d. for 28 lb. lots.
Magnesium Carbonate—	
Light Commercial ..	£36 per ton net.
Magnesium Oxide—	
Light Commercial ..	£80 per ton, less 2½%.
Heavy Commercial ..	£27 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 75s. per lb.
Mercurials	Market dull.
Methyl Salicylate ..	2s. 6d.—2s. 10d. per lb. In steady demand.
Methyl Sulphonal ..	14s. 6d. per lb. No demand.
Metol	8s. 9d. per lb.

Morphine and Salts ..	Prices again advanced owing to dearness of opium. Alkaloid : Cryst. 14s. 8d., Precip. 14s. 5d., Acetate 11s. 6d., Hydrochlor. 11s. 6d., Sulphate 11s. 6d., Tartrate 14s. 5d. per oz.
Paraformaldehyde ..	3s. 6d. per lb. More active.
Paraldehyde	1s. 5d.—1s. 5½d. per lb. Average price in 5 lb. bottles. Higher prices expected when stocks are absorbed.
Phenacetin	6s. 3d. per lb. Demand steady. Moving to higher prices.
Phenazone	7s. 6d. per lb. Firm.
Phenolphthalein ..	6s. 6d. per lb. Scarce.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½%. Demand fair.
Potass. Ferricyanide ..	3s.—3s. 6d. per lb.
Potass. Iodide	15s. 8d.—16s. 2d. per lb. Good demand.
Potass. Permanganate ..	10d. per lb. for B.P. crystal.
Quinine Sulphate ..	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb. Higher prices expected.
Salol	3s. per lb. Limited demand.
Sod. Benzoate	2s. 6d. per lb. Spot price lower than replacement value owing to lack of demand.
Sod. Citrate, B.P.C. 1923	Reduced to 2s. per lb. for cwt. lots. Makers kept active.
Sod. Hyposulphite—Photographic ..	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Potass. Tartrate (Rochelle Salt) ..	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 8d. per lb., and Crystal at 2s. 11d. per lb. Firm, with tendency to rise. Large orders in hand.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.	
Aubepine	14s. ,, ,,	
Amyl Acetate	3s. ,, ,,	
Amyl Butyrate	7s. 3d. ,, ,,	
Amyl Salicylate ..	3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,	Higher prices anticipated.
Benzyl Alcohol free from Chlorine	3s. ,, ,,	
Benzaldehyde free from Chlorine	3s. ,, ,,	
Benzyl Benzoate ..	3s. ,, ,,	
Cinnamic Aldehyde Natural	20s. ,, ,,	
Coumarin	18s. ,, ,,	
Citronellol	19s. 6d. ,, ,,	
Citral	9s. 6d. ,, ,,	
Ethyl Cinnamate ..	10s. ,, ,,	
Ethyl Phthalate ..	3s. 9d. ,, ,,	
Eugenol	10s. ,, ,,

Geraniol	6s. 9d. to 13s. 6d. per lb.	
Heliotropine	8s. per lb.	
Iso Eugenol	15s. per lb.	
Linalol ex Bois de Rose ..	18s. 6d. ,, ,,	
Linalyl Acetate	18s. 6d. per lb. Considerably cheaper.	
Methyl Anthranilate ..	8s. 6d. per lb.	
Methyl Benzoate ..	6s. ,, ,,	
Musk Ketone	40s. ,, ,,	
Musk Xylol	12s. 6d ,, ,,	
Nerolin	4s. ,, ,,	
Phenyl Ethyl Acetate ..	10s. ,, ,,	
Phenyl Ethyl Alcohol ..	15s. ,, ,,	
Rhodinol	47s. 6d. ,, ,,	
Safrol	2s. ,, ,,	
Terpineol	3s. ,, ,,	
Vanillin	22s. 6d.—23s. per lb. Firm and steady demand. Raw material dearer.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. ,, ,,
Bergamot Oil	14s. ,, ,, apot.
Bourbon Geranium Oil ..	37s. ,, ,,
Camphor Oil	80s. ,, ,,
Cananga Oil, Java ..	9s. ,, ,,
Cinnamon Oil, Leaf ..	4¾d. per oz.
Cassia Oil 80/85% ..	11s. 6d. per lb.
Citronella Oil—	
Java 85/90% ..	4s. 2d. ,, ,,
Ceylon	4s. per lb. Very little on offer, too many parcels arriving spirit. These have been seized by the Customs.
Clove Oil	8s. 6d. per lb.
Eucalyptus Oil 70/75% ..	2s. 9d. per lb.
Lavender Oil—	
French 38/40% Esters	26s. per lb. Reliable offers are difficult to obtain and very high prices for new crop oil seem inevitable.
Lemon Oil	2s. 10d. per lb. Very high prices are being asked at the source.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet ..	12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil ..	24s. 6d. per lb.
Peppermint Oil—	
Wayne County ..	15s. per lb. Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	8s. per lb. Dearer.

TRADE NOTES

Disinfectant Fluid for South Africa

His Majesty's Senior Trade Commissioner in South Africa (Mr. W. G. Wickham) reports that the South African Railway Administration are calling for tenders for the supply of disinfectant fluid during the period January 1, 1924, to June 30, 1924. (Tender No. 482.)

A copy of the tender form, specification, and conditions of tender is available for inspection by United Kingdom firms at the Department of Overseas Trade, 35, Old Queen Street, London, S.W. 1. (Ref. No. 12,337 E.D./C.C./2).

Chemicals (Coagulants) for South Africa

His Majesty's Senior Trade Commissioner in South Africa (Mr. W. G. Wickham) reports that the Rand Water Board are calling for tenders (contract No. 249) for the supply and delivery of 150 short tons, or alternatively 300 short tons, aluminium sulphate or alumino-ferric, on or before noon on Friday, November 9, 1923.

A copy of the tender form, specification, and conditions of tender is available for inspection by United Kingdom firms at the Department of Overseas Trade (Room 52), 35, Old Queen Street, London, S.W. 1. Reference No. 12,342/E.D./C.C./2.

Trade Notes from France

At a recent meeting of the Groupement des Sociétés Naphtifères Russes in Paris under the presidency of Sir H. Deterding, it was decided to begin negotiations at once with the Soviets for the protection of the group's interests in Russia.

The Société Anonyme d'Explosifs et de Produits Chimiques has installed new plant for distilling glycerin in its factory at St. Martin.

Export of Rubber Latex from Malaya

Rubber latex first appeared in the monthly return of exports from British Malaya in June, 1922. Since that date to the end of June, 1923 (13 months), a total of 97,015 galls., valued at £18,973, was exported, 72,409 galls. going to the United Kingdom, 20,792 galls. to the United States of America, 2468 galls. to the Continent of Europe, 720 galls. to British possessions, and 626 galls. to Japan. Investigations on the use of latex in pulp for paper making are largely responsible for this new development of the rubber industry. Experiments have also been conducted with latex in the manufacture of paints, varnishes, chewing gum, and in the waterproofing of cloths. The preservation and shipment of rubber latex in large quantities present considerable difficulties. Ammonia is the chemical recommended as a preservative. If time should bring any considerable demand for rubber latex satisfactory containers will be required, as no one of those now used—kerosine oil tins, petrol drums, crude oil drums, wooden barrels and other types of vessel—entirely satisfies all the requirements of an ideal type of container.—(*Malay States Information Agency.*)

Change of Address.—The offices of Messrs. Newitt and Son, chemical and process engineers, and agents for "Powminco" Asbestos Gooch filter fibre, have been removed to 17, Waterloo Place, Pall Mall, London, S.W. 1. Cablegrams: Enewitt, London. Telephone Nos.: Regent 899 and 159.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, OCTOBER 26, 1923 No. 43

EDITORIAL

THE letter which we print in this issue from Mr. Doran interested us a great deal, especially the paragraph in which he indicates that twenty years in the laboratory and lecture room will lay a sure foundation, and that immediately upon their completion the necessity arises for the inculcation of business responsibility. Our own belief is that if a student sticks to his laboratory, say, from the age of eighteen until he is thirty-eight, with occasional interludes in the earlier part of this period in the lecture room, neither he nor his employer has any right to expect him to become a tolerable man of business. Let us take one instance; suppose such a man at the age of thirty-eight is asked to take charge of a new development, how is he to have acquired the judgment necessary to know what working capital is required, what the cost of his new works and plant will be, and other such vital factors? This judgment is not acquired in the laboratory, it is usually the result of experience which has involved months of worry and anxiety and a considerable loss of money. Our belief is that no one with sound business instincts would ever spend twenty years in laboratories and lecture rooms. A chemist might be a first-class chemist and have a very clear idea of the cost of various chemical operations, and might yet be an appalling man of business. Some men may learn at home a great deal of the essentials of business ways of thought just as they pick up a good taste in literature or pictures; they do this by association with those who are good judges. But a man who has not this early advantage must learn business sense by experience, and if he has any taste or aptitude for business methods he will certainly have made some business experiments on his own account before he is of the age of thirty-eight.

On the business training of chemists we have no wish to be unduly dogmatic or emphatic. Everyone has his, or her, own ideas as to how business propositions should be looked at and the sort of training required. Fortunately, among our chemists are many who, whether or not they have that *auri sacra fames* which is characteristic of some of our greatest men in industry, are both sensible and business-like. The Councils of the Chemical Society and the Society of Chemical Industry have within the last few days decided to form a Bureau of Chemical Abstracts which would be responsible for the preparation and issue of the abstracts at present issued separately by the two Societies. It is recognised that there are considerable difficulties in the way of complete unification of the two sets of abstracts, but it is believed that these can be solved and that the experience gained by the Bureau will be very helpful in suggesting economies and improvements. It is anticipated that the Bureau will be able in due course to submit to the Councils of the two Societies a scheme for further co-operation. Meanwhile it is proposed that the present form of the two sets of abstracts should be retained. This decision of the two Societies is an important step, and has, no doubt, required a good deal of time and thought to arrange. We hope that the Bureau, which will include four prominent men from each of the two Societies, will be able in a few months to make an interesting report on the whole situation; the experience they will gain will enable them, or perhaps compel them, to consider the possibility of arranging some comprehensive scheme which will include not only the abstracts of the two Societies who are now interested, but also the abstracts published by other chemical organisations both in this country and in those other countries where abstracts in the English language are required. Some such sets of abstracts might conveniently be treated in such a scheme; in other cases geographical or financial difficulties may be insuperable.

* * *

A number of interesting questions have been raised by the discussion which has appeared in these columns on the place of the chemist in industry, and on the attributes of the chemical—or is it "physico-chemical?"—engineer. That finality has not been reached is a sign of health in the body chemical; indeed, we are not sure that it could be reached. The discussion must always be general, the industrial application special. Both chemists and chemical engineers find employment, so the decision must perforce be left to those who employ them, as their respective utility, whether as "thinkers" or "doers," must ultimately be capable of material demonstration. In a further contribution to the discussion which we publish in this issue, Mr. Gray's remark that the distinction between pure and applied chemistry is largely one of time, reminded us of an example. A century ago—to be precise, on July 27, 1823—Johann Wolfgang Doebereiner, professor of chemistry, pharmacy and technology at Jena, discovered that spongy platinum in presence of oxygen can bring about the ignition of hydrogen. This discovery was made as a sequel to previous researches on the oxidation of alcohol to acetic acid and water by means of platinum black, and Doebereiner utilised it in making his "hydrogen lamp," of which the so-called "self-lighters" for coal gas are descendants. In the course of further work it was found that by the same means sulphur dioxide and oxygen could be induced to combine to form sulphur trioxide. The importance of this discovery was at once realised, and in 1831 Peregrine Philips made the reaction the subject of a patent. Commercially, however, the process proved impracticable, and success was only attained after 1875, when Squire and Messel in London, and Winkler in Freiburg, were induced to explore its possibilities by the increasing demand for fuming sulphuric acid, which had hitherto been made solely by the clumsy Bohemian process. The exact date when the "contact" process was perfected is uncertain, as but scant data have been published, but the interval of, at least, over fifty years shows the lag between discovery and application. Indeed, the "pure" chemistry of the process could probably be traced still further back, as the term "catalysis" was introduced by Berzelius, Faraday studied the acceleration of the combustion of hydrogen and oxygen due to the presence of platinum, and platinum was first described as a new metal by Sir William Watson in 1750. "The centuries are lineal children of one another; and often, in the portrait of early grandfathers, this and the other enigmatic feature of the newest grandson will disclose itself." And, as Goethe said, everything in life, to be of value, must have sequence.

POWER AND BORIC ACID FROM NATURAL STEAM IN TUSCANY

One of the most romantic of the European chemical industries is that which is being rapidly developed by the Società Boracifera di Larderello under the leadership of our honorary member, the Prince Piero Ginori-Conti. The company has established seven works within an elliptical area some forty or fifty miles south-south-west of Florence, namely, at Larderello, Castelnuovo, Sasso, Monterotondo, Lago, Lustignano and Sarrazzano, and an eighth which lies eastward at Travale; in these, the volcanic steam is utilised first to produce electrical power and afterwards for the manufacture of boric acid.

Fig. 1

The steam springs all lie on the slopes of the hills dividing the valleys of the Cecina and Cornia rivers; they are approached by excellent roads from Florence through some of the most magnificent scenery in Tuscany. The roads are tortuous, partly owing to the mountainous nature of the country and partly because they serve the numerous towns and villages, which are all built, from motives of prudence, on hill-tops in positions which could be strongly fortified. The journey of 70 or 80 miles from Florence to Larderello may be made either through Volterra, the gigantic fortifications of which stand almost as intact as when they were built by Lorenzo the Magnificent in the fifteenth century, or through Siena, which retains its mediæval aspect even better than most of the old Italian towns. The proximity of the steam springs is revealed in the replacement of the luxuriant fertility of

Central Italy by stretches of arid soil and rock and by the smell of hydrogen sulphide, a constituent of the escaping water vapour; it is notable that the odour of the latter is sweet and devoid of any nauseating effect, and that after a few hours any silver articles which one carries acquire a black tarnish which rapidly increases in depth of colour. Here and there steam may be seen escaping from the earth, and areas are remarked in which many jets of steam escape and where the soil is too hot to touch; these spots are interesting in that they are the seats of actual mineral formation. The borders of the orifices from which the steam issues are fringed with growing crystals of sulphur, the product of interaction between hydrogen sulphide and the sulphur dioxide formed by atmospheric oxidation at the high temperature. All around lie boulders of crystalline calcium carbonate, which are coated thickly, often to a depth of six inches, with a pseudomorphous growth of crystalline calcium sulphate, gypsum, formed by the action of the oxides of sulphur contained in the atmosphere.

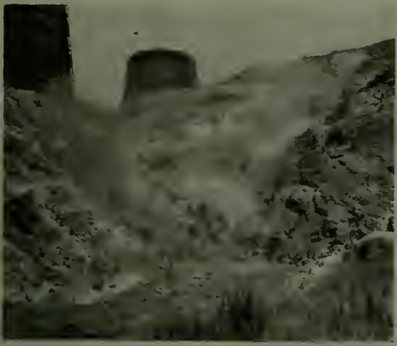

Fig. 2

The steam which emerges through these natural crevices or "suffioni" (Fig. 1), or which escapes through pools of water called "lagoni" (Fig. 2), is not great in quantity; the large sources of natural steam have been tapped by boring, and emerge from boreholes up to 40 cm. diameter and 180 metres deep. The boreholes are lined with iron tubes, a wide one going to the bottom enclosing a smaller one with the annular space filled in with concrete and enclosing others of still smaller bore similarly secured; essential joints are made with the oxyhydrogen blowpipe, hydrogen and oxygen being prepared by the electrolysis of caustic soda solutions. The steam thus tapped is delivered at the top of the boring at pressures up to nine atmospheres and at temperatures up to 180° C., although the mean pressures and temperatures are much lower than these values; it is estimated that some 600,000 kg. of water vapour per hour are thus in sight, although the quantity at present utilised is much smaller. At Larderello alone 135 boreholes are being utilised, and the issuing steam has a mean temperature of 120–130°.

The escaping steam contains up to 0·1 per cent. by weight of boric acid, the mean content being about 0·06 per cent., and also about 6 per cent. by volume of gases other than water vapour; these consist mainly of carbon dioxide with smaller quantities of hydrogen sulphide, nitrogen, oxygen, methane, hydrogen and helium. The presence of about 6 per cent. of gases uncondensable at ordinary temperature makes it inconvenient to use the pressure steam directly as a source of power; it is therefore used for the purpose of raising steam from boiling water, the secondary steam producing power by passage through turbines fitted with vacuum condensers. The electrical energy generated is distributed at 36,000 volts on a three-phase alternating current system for use at Siena, Volterra, Florence and a number of works within a radius of some thirty miles; the output of power seems only to be limited at present by the demand, and it is clear that it may be vastly increased as need arises. The presence of hydrogen sulphide in the atmosphere has necessitated the replacement of copper by aluminium in the electrical conductors.

Fig. 3

During the conduction of the steam to the turbines and its subsequent reduction in potential, large quantities of condensed water containing boric acid in solution are obtained. This water is evaporated in series of shallow lead-lined troughs, working on a counter-current principle, by means of the partially exhausted steam; the highly concentrated boric acid solutions which thus result deposit crude boric acid which is collected at Larderello and purified by re-crystallisation. The production again is in its infancy; the works at Castelnuovo in the Val di Cecina produces actually about 10 tons of boric acid per day, but aims at a production of 20 tons. The same works has begun to utilise the waste carbon dioxide contained in the steam and already manufactures 10 tons of ammonium carbonate per month, not in powder but in crystalline masses. The evaporation troughs are shown in the middle of Fig. 3, and it will be seen that they present little resemblance to the concreted tanks shown in our most modern text-books as used in the preparation of boric acid.

The situation of Italy as concerns power production is peculiar; in the north water power from the Apennines is available, and near Pisa natural gas is being used. Prolonged droughts make water power precarious in other parts of the kingdom and, although peat and lignite are used, little economic value attaches to the exploitation of these and other power-raising media. In the Province of Pisa, where none of these sources of power or heat are readily available, the initiative of the Società Boracifera has harnessed the volcanic steam for the production of power and has developed the economic production of boric acid in such a manner as to make the manufacture entirely self contained—namely, quite independent of the use of imported fuel or chemicals. This achievement has involved the exercise of considerable engineering skill and also a profound chemical study of the components of the steam and the modes of chemical treatment appropriate to their economic separation. Much of this chemical work has been done by Prof. Raffaello Nasini, who is at present compiling a book on the subject. The manufacture of boric acid is now upon a sound basis, and attempts are being made to utilise the minor constituents of the steam; at Castelnuovo the carbon dioxide, as noted above, is already converted into ammonium carbonate by a satisfactory process and the work is developing in yet other directions.

It is interesting to contrast the Tuscan manufacture of boric acid, which involves evaporation by volcanic heat, with the Californian manufacture, which still provides the major part of the world's needs. In the latter, calcium borate has to be decomposed with hydrochloric acid before a solution is obtained from which boric acid is separated by evaporation, fuel being required for this latter operation. The Italian process seems to have marked economical advantages.

The volcanic steam is markedly radioactive, that of Larderello being especially rich in emanation, as Nasini has shown. Whilst driving or riding through this magnficent country—up wooded hills from the summits of which the Island of Elba can be seen and down into valleys thick with vines and fruit trees—it is seen that the situation is ideal as that of a health resort. This notion may soon pass into execution, for Italy has changed greatly during the last two years. Beggars have almost disappeared from the towns and a new air of alertness is evident everywhere; employer and employed fraternise with a cordiality little known in England. In fact, Italy has suddenly become the most democratic country in the world.

THE CHEMIST AND INDUSTRY

Another Point of View

By J. H. WEST, A.M.Inst.C.E.

The discussion ably started, or rather revived, by Mr. H. H. Gray under the above title is undoubtedly of national importance, and it is to be hoped that it will be continued with adequate representation of all points of view, and especially that of British chemical manufacturers themselves.

The present writer's endeavour will be to examine the subject from the point of view of a keen student of the science of organisation and also from that of the chemical engineer. The views expressed may be right or wrong; they are not put forward in any dogmatic spirit, but as the result of a good many years of thought and not a little experience.

Mr. Gray complains, not without reason, that employers undervalue a University trained mind, but I venture to think that his own remark as to anxiety about costs being beside the mark throws much light upon the reason for this. The question of costs, the difference between profit and loss, is the life or death of industry. No amount of the most brilliant research work will avail if the process does not show a profit. This may be a sordid fact, and one repugnant to the high ideals of pure science, but there it is. Let me give an illustration.

It happened a few years ago in a very large concern which shall be nameless. The manufacture of a certain product on a large scale was under consideration by the advisory committee, which consisted not only of the active directors and the heads of the technical staff, but also of University professors. One of these professors, undoubtedly one of the foremost authorities in the country on the subject, had been asked to work out a new and improved process for making this product, to take the place of an old process which had been in use for some years on a small scale. After what was no doubt a brilliant piece of research, he submitted a new process, the great point of which was that a much better yield of product was obtained from a given quantity of the substance which was the starting point of both processes. After that, for well over twelve months a large part of every meeting of the advisory committee was devoted to a discussion of the relative merits of the two processes. This discussion between the old school and the new became very bitter, but no decision was arrived at. At last an engineer was asked to get out the comparative cost of plant for the two processes, in the hope that this factor might prove decisive; but it was found that there was not much to choose between them. Still no decision. Then it occurred to the engineer to make a comparison between the cost of materials —*all materials*—in the two cases. To do this he had to ask for the prices of the various reagents used. For some time this information was refused, and he was bluntly told to mind his own business and stick to the engineering side. Finally, however, pressure was brought to bear, and the information was reluctantly given. In half an hour he was then able to show that while the new process saved less than a halfpenny per pound of product on the primary raw material, it cost for other reagents something like two shillings per pound of product more than the old process. That ended the discussion right away.

Mr. Gray says that from the point of view of the chemist there is very little difference between real science and ideal industry. Unfortunately real industry is far from being ideal, and that is why the raw University graduate, who has not been taught to think industrially, is of little use to the employer until he has had time to readjust his mental values to the hard facts of profit-making.

Now as to the chemical engineer. Much harm has been done by incompetent people calling themselves chemical engineers. That should come to an end with the establishment of the Institution of Chemical Engineers, which will exercise control over the qualifications and competence of chemical engineers. Quite as much harm can be done by the few, if, indeed, there are any, who claim that a chemical engineer can supersede or do the work of a chemist. Obviously no man can be fully trained and experienced in both chemistry and engineering. To begin with, supposing a man could be found with sufficient ability in both directions, the double training would take nine or ten years. The genuine chemical engineer is not in any way the industrial chemist's rival, but rather his best friend.

What, in the writer's opinion, is wanted is a cessation of futile discussion as to who is to be top dog, and the adoption of a spirit of mutual co-operation, of team-work, based upon each man doing the work for which he has been trained. The chemical manufacturer has to make profits, and he has to build up a very complicated organisation to handle the many factors involved. The specialists employed, whether chemists, engineers, process managers, cost accountants, buyers, financial experts, or sales managers, must all work together to the common end of helping to make profits. It is as futile for one branch to claim paramount importance for itself, as it would be to single out the nervous system, the circulation of the blood, or the alimentary system, as the most important factor in the life of the human organism. All are equally essential.

All these specialists have their own ways of thought and their own particular jargon, and they are often as much at cross purposes with each other as the builders of the tower of Babel. Let each and every specialist stop worrying whether he is the most important man and should therefore have control, and let him remember that his work is, after all, only one phase among many, all of which working in harmony are essential to success. For satisfactory team-work in games it is necessary that each player shall not only play for his side and not for himself, but that he shall know the individual peculiarities of every member of his side. Similarly, members of different branches of an industrial organisation should be familiar with the work, the outlook, and the difficulties of their colleagues. They can then understand each other better, and appreciate each other's point of view.

Mr. Gray suggests that the chemist should be administrative (" thinking "), and the engineer executive (" doing "). Does he not realise that " thinking " is absolutely necessary in every branch? The " most scientific, the least complex, and the most beautiful plant," to which Mr. Gray refers elsewhere, will certainly not be evolved by chemical research alone, but only by the most earnest co-operation between chemist and engineer, and the expenditure of an immense amount of thought and an infinitude of pains by each of them.

Except in the very largest organisations it is not possible to employ separate people for thinking and doing. In most cases the same man has to do some of each, acting as executive to those in authority over him, and in an administrative capacity to those under his authority. This is unfortunate because a man whether chemist or engineer, who is perpetually bothered with details of executive routine cannot devote his attention properly to thinking out administrative problems.

That brings us to the distinction between doing research and thinking out research. There are many chemists, and this is particularly true of raw University graduates, who are quite competent to carry out the experimental part of a research on lines laid down for them, but in the writer's opinion there are very few who are capable of taking an average industrial chemical problem and thinking it out in all its bearings so that the expensive experimental work is reduced to a minimum. There must be hewers of wood and drawers of water in every department. Routine analyses must be made and plant must be repaired, but the man who has learnt to think industrially will become too valuable to be kept at such work.

British manufacturers do restrict their technical men too much to executive work. It would pay them better if the best of the technical men were taken more into their inner councils, and I think that if the spirit of industrial objective and team-work were better developed this would be done far more than it is. In this connexion it has often struck me that technical men as a rule are not skilful in the way they bring their proposals before business men. The latter like crisp short reports supported by definite figures, with every essential factor in the problem clearly set out in as non-technical language as possible, and nothing irrelevant left in, showing that the whole scheme has been thoroughly thought out in every detail before being submitted.

Finally a word may be permitted on the subject of thoroughness. Chemists are rather apt to bring forward processes before they have been fully worked out in the really minute detail necessary for satisfactory working. The physical factors which the chemical engineer must have to design the plant properly, such as specific heats, heats of reaction, volumes of filter cake and so on, are often neglected, and sometimes the engineer is to blame in not insisting upon having proper data before making his designs. The preparation of a quantitative flow-sheet, showing the path and ultimate destination of every pound of matter entering the process is a splendid means of finding out how much is really known about the process, and is too rarely used. This, combined with heat and energy flow-sheets, gives the whole story in the form most intelligible to both chemist and engineer. Do not let our overseas competitors beat us by greater thoroughness.

"COPPER ORES"

The monograph by R. Allen, bearing the above title, is issued by the Imperial Institute (220 pp., John Murray, 7s. 6d. net), and contains chapters on "Occurrence, characters and uses," "Sources of supply, Empire and foreign countries," and a carefully compiled list of references arranged generally and geographically. The monograph is a conveniently arranged digest of published statistics and information, official and unofficial, and its publication, rendering such matter more readily available, would have been justified had the Imperial Mineral Resources Bureau not already issued a pamphlet covering much the same ground.

CHEMISTRY AND THE BLEACHING INDUSTRY

By S. H. HIGGINS, M.Sc.

In considering the development of the bleaching industry during the last hundred and fifty years, it is interesting to point out to chemists of the present day that, both as regards the materials used in the industry and the methods employed, changes and improvements were always introduced by chemists. At the beginning of the period mentioned the industries of chemical manufacture and of bleaching were sometimes carried on together, with the result that chemistry was brought to bear on the bleaching industry and, as will be shown, completely revolutionised the industry and enabled it to deal with the large quantity of cloth which was being turned out by the power loom.

In early times bleaching was carried out in a crude manner in all countries and often by farmers. The webs of cloth were heated or 'stewed' in a solution of plant ashes (usually obtained by burning weeds), then washed, steeped in butter milk, washed and exposed to the sun on the grass. This treatment was repeated until the goods were white. The farmers had the weed ash, the buttermilk and the fields, so that it can be readily understood how bleaching became a kind of subsidiary industry to agriculture. Large areas of agricultural land were used for the grassing of the cloth and as the output of the looms increased this tying up of agricultural land became a consideration. The introduction of different chemicals into the industry enabled the bleacher considerably to hasten his process, and for most classes of goods to eliminate the grassing operation altogether: if chemistry had not done this the whole of Lancashire would be required at the present time to grass the cloth which is now bleached in that county.

The first radical alteration which chemistry introduced into the bleaching industry was the use of sulphuric acid in the place of buttermilk, the juices of crab apples, lemons, etc., for souring the cloth. Then the introduction of chlorine compounds as whitening agents completely revolutionised the industry. Lime came into use as a scouring agent in place of plant ashes and sometimes the lime was added to the ash solution to causticise it and make it a more effective scouring agent. The production of artificial soda provided the bleacher with purer materials than he had been used to and also placed at his disposal another acid, namely, hydrochloric acid, of which he soon made use. Later, the production of cheap caustic soda enabled the bleacher in some cases to dispense with lime boiling, to return to soda boiling, and to shorten his process.

These advances in chemical industry had a tremendous effect on the bleaching industry. The time required for bleaching cotton goods was reduced from months to a few days, and occasionally goods were bleached in 24 hours. But the changes mentioned were not allowed a smooth entry into the industry. For instance, the British Government stipulated in 1823 that no acids should be used in bleaching government material; any bleacher using lime for bleaching in the eighteenth century was liable to be hanged; the use of hypochlorites for whitening was not well received by French bleachers when Berthollet displayed their action, and British bleachers in many cases did not approve of their use, for in 1823 a Cheshire calico printer was still grassing his cloth and using no hypochlorite for whitening.

Gradually, however, these prejudices were overcome and it is not difficult to understand, with our present-day experience, why the objections arose. When acid is employed carelessly and not well washed out of the cloth it causes "tendering," and if hypochlorites are not carefully used they also rot the cloth. In the case of lime, tendering in the lime boil sometimes occurs and if lime is added to ash solution, to produce a caustic solution, care is required in using this, because in some cases in the presence of air tendering of the cloth takes place. It is probable that when first used all these new agents caused some cloth to become tender, but with experience bleachers began to use the new materials without causing injury to the cloth and then prejudice disappeared because it became recognised that the new materials produced a bleached cloth much superior to that produced by the old long and tedious methods. Nowadays, by the chemical control of the process, scientific investigation from many points of view has shown that the modern process of bleaching produces an article which for strength, weight, colour and handle would be difficult to improve upon.

As regards the effect of hydrochloric acid on the bleaching industry, its introduction to bleachers enabled them to sour the cloth after the lime boil. In 1823 it was known that by washing the cloth out of the lime boil, and then souring in sulphuric acid a very good effect was obtained; but it was also known that this system of bleaching produced a deposit of calcium sulphate in the cloth, a deposit which could not be removed by subsequent treatment. The lime sour was, therefore, abandoned and it was not used in the industry until about 1840, when bleachers were able to obtain hydrochloric acid, which did not cause a deposit on the cloth. This change was introduced into the industry from Mulhouse, and shows another example of the effect of progress in chemical manufacture on the development of the bleaching industry.

Dr. E. F. Armstrong* has shown the development of the alkali industry in this country, and from his account the effect on the development of the bleaching industry can easily be traced; Berthollet (*The Art of Dyeing*) has described the effect of hypochlorites on the bleaching industry; and the present writer has traced these and other effects at length in a series of articles appearing in the current numbers of the *Journal of the Textile Institute*, but it is of interest to note the effect of the chemist on the bleaching industry during the last hundred years.

The effect has been small. The process of bleaching as carried out in 1823 is practically the same from the chemical point of view as that used at the present time. Alterations in details and improvements of a minor character have, of course, been made; but the fact remains that as regards the chemical side nothing revolutionary has taken place. And this state of affairs is not difficult to understand. Chemistry had had its innings and it had been a glorious one. It had completely revolutionised the industry and enabled it to turn out the quantity of material which was demanded of it. The bleaching industry had been developed along with the chemical industry by such men as Tennant and Bealey, so that chemical knowledge had been brought to bear on it to the fullest extent. In short, the bleaching industry had been made a chemical industry. It is not right to say that the bleaching industry is founded on "empiricism" and "rule of thumb"; it is founded on the chemical discoveries of the latter half of the eighteenth century, and by 1823 we find a system of chemical control introduced into the industry which amazes those with a knowledge of present-day methods. In fact, the bleaching of 1823 was as well controlled from the chemical point of view as much of that of to-day.

After the turn of the chemist the engineer had a large effect on the industry, and by introducing machine bleaching enabled it to cope with the development of the cotton trade and the large quantity of cloth sent to the bleacher. The chemist had to take a back seat; he seldom found employment in the industry except where calico printing and dyeing were carried on under the same roof, and it is manifest that the industry suffered accordingly, but it is interesting to recall that some distinguished chemists were connected with the bleaching industry during the last century.

John Dalton tested the water at Sykes' Edgeley bleach works in 1826, and Crace Calvert was consulted by the same firm in 1851. The Sykes family studied chemistry and confirmed their findings by consulting outside authorities. Other bleachers had consulting chemists, but the study of chemistry by bleachers themselves became less and less. Sir William Crookes was engaged in colour printing at one time but left it for pure science. Many bleachers consulted German chemists because in later years their fame in dyestuff manufacture seemed to infer a knowledge of the chemistry of textile fibres, but the records show that these consultations did not always yield happy results. C. F. Cross was engaged for some time at a Lancashire bleachworks in developing a new process of bleaching, and at the same works was a chemist, Horace Lowe, who discovered the process of lustring cotton by treating it in the stretched condition with caustic soda solution. Mercer, Horace Koechlin and others might also be mentioned, but the names are few; in fact, too few to keep the industry on the stage of a chemical industry as it was founded.

* Presidential Address, *Chem. & Ind.* 1923, June 22, p. 603.

THE WORLD'S PETROLEUM PRODUCTION

By H. G. SHATWELL, B.Sc.

The following table, based on estimates prepared by the American Petroleum Institute, shows the variations in the world's production of petroleum for the four years, 1919 to 1922 :—

Table I—*The World's Production of Petroleum* 1919-1922. Estimates in thousands of barrels by the American Petroleum Institute

	1919	1920	1921	1922
United States..	377,719	443,402	469,639	551,197
Mexico ..	87,073	163,540	195,064	185,057
Russia ..	34,284	25,430	28,500	35,091
Dutch East Indies ..	15,780	17,529	18,000	16,000
India	8,453	7,500	6,864	7,980
Sarawak ..	—	—	1,411	2,915
Rumania ..	6,518	7,435	8,340	9,817
Persia	6,290	12,353	14,600	21,154
Poland-Galicia	6,255	5,606	3,665	5,110
Peru	2,561	2,817	3,568	5,332
Japan and Formosa ..	2,121	2,140	2,600	2,004
Trinidad ..	2,780	2,083	2,354	2,445
Argentina ..	1,504	1,666	1,747	2,674
Egypt	1.662	1,042	1,181	1,188
France-Alsace-Lorraine ..	—	389	392	494
Venezuela ..	321	457	1,078	2,335
Canada ..	220	197	190	178
Germany ..	925	212	200	200
Italy	38	34	35	31
Algeria ..	—	4	3	9
England ..	—	3	3	—
Colombia ..	—	—	—	323
Other countries	—	1,016	1,000	5
Totals ..	554,504	694,855	760,434	851,539

It will be observed that steady increments in the quota of oil are provided by the Argentine, Venezuela, Peru and Rumania, whilst decreases occur in Canada, Egypt, Poland and Germany. An interesting case is that of Persia, whose output—more than trebled in the period under review—now comes in the fourth position in the table, from which the Dutch East Indies has been ousted.

The table also serves to show to what extent the oil situation is dominated by the United States and Mexico. These countries between them supply 86 4 per cent. of the world's total output, the United States contributing 64·7 per cent. and Mexico 21·7 per cent.

Table II and Fig. 1 below give details for the United States and Mexico for the last ten years, and indicate clearly the wonderful development which has taken place with regard to the latter country. The slight decrease for 1922 is due to the fall in the price of crude oil, to lack of transport and storage facilities, and to political causes.

Table II

Oil production in thousand barrels

Year	Mexico	United States	World	Mexico %	U.S.A. %	Total %
1913	25,902	248,446	384,668	6·7	64·6	71·3
1914	21,188	265,762	399,667	5·3	66·5	71·8
1915	32,910	281,104	426,371	7·7	66·0	73·7
1916	39,817	300.767	459,433	8·6	65·5	74·1
1917	55,293	335,315	505,362	10·9	66·4	77·3
1918	63,828	355,928	514,729	12·4	69·1	81·5
1919	87,073	377,719	554,504	15·7	68·0	83·7
1920	163,540	443.402	694,855	23·5	63·9	87·4
1921	195,064	469,639	760,434	25·6	62·0	87·6
1922	185,057	551,197	851,540	21·7	64·7	86·4

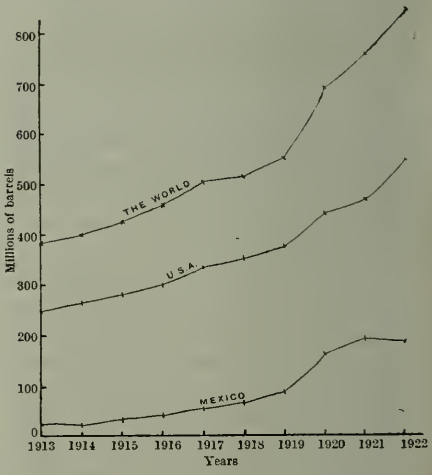

Fig. 1

United States

The influence of the United States upon the supply of crude oil is affected very considerably by the huge demand of that country for petrol and other fuel oils. It has been estimated that over two and a-half million motor vehicles were manufactured in the United States during 1922, bringing the number of cars in service to the huge total of twelve million, excluding farm tractors and stationary gasoline engines. Consequently, an interesting race between production and consumption is being witnessed, and the following table (III), showing consumption as estimated by the U.S. Geological Survey, indicates that the United States is now quite definitely an oil-importing country :—

Table III

Year	Production	Consumption	Deficit
	Thousands of barrels		
1916	300,767	318,599	17,832
1917	335,315	377,736	42,421
1918	355,928	413,078	57,150
1919	377,720	420,462	42,742
1920	443,402	530,532	87,130
1921	469,639	526,032	56,393
1922	551,197	587,000	35,803

The annual deficit is being made up principally by increased importations from Mexico, though many of the United States fields such as Arkansas, Oklahoma, California, Wyoming and Montana, are themselves producing greatly increased amounts of oil. It should be noted, however, that these new supplies of oil are poor in low-boiling constituents, and that consequently serious doubts are felt as to future supplies of straight-run petrol. The effect of this is to direct more attention to other sources of motor-spirit, particularly the " cracking " of heavy oils, the provision of blended motor-spirit, and the utilisation of benzol, alcohol, ether, acetone, etc., whilst a great impetus is being given to the exploitation of new oil fields and of oil-shale deposits.

ANTI-KNOCK GASOLINE

Gasoline to which tetra-ethyl lead has been added to prevent " knocking " is now being marketed in Dayton, Ohio, under the name of " ethyl gas." An apparatus known as an " ethyliser " has been devised to fit any gasoline pump and add the anti-knock compound in the proper proportion. The best results are obtained with 3 c.c. of tetra-ethyl lead and 2 c.c. of carbon tetrachloride per gallon of gasoline. The use of tetra-ethyl lead alone causes the rapid deterioration of the sparking plugs, but with carbon tetrachloride added, lead chloride is formed and readily passes out through the exhaust. The only disadvantage noted thus far is the deposit of some white lead chloride in the combustion chamber and exhaust valves. Whilst ethyl gas is no better for a motor than benzo-gas, the latter is sold for 6 cents. per gall. more than gasoline, and ethyl gas costs but 3 cents. per gall. more. If the use of anti-knock compounds becomes general enough, so that higher compression motors can be built, almost double the mileage could be obtained from a gallon of gasoline. The General Motors Corporation has built such a motor and has been able to get 31·5 miles per gallon, whereas 16 miles is a good return with the present type.—(*Chem. & Met. Eng., Sept.* 24, 1923).

OBITUARY

WILLIAM THOMSON

Mr. William Thomson, F.R.S.(Ed.), F.I.C., F.C.S., the well-known consulting chemist and analyst who died so suddenly in his laboratory, on Thursday, October 4, was a prominent figure in the chemical circles of Manchester and London during the last fifty years.

Born in 1851 in Glasgow, he came to Manchester in 1869, and entered as assistant to Dr. Crace-Calvert, in the Royal Institution Laboratory in Princess Street, the oldest chemical laboratory in Great Britain. Four years later, on August 25, 1873, at the age of twenty-two years, he became a partner in the firm of Crace-Calvert and Thomson, and on the death of Dr, Crace-Calvert two months later took sole charge of the practice, and combined with this the office of Public Analyst for Stockport, which he continued to the moment of his death.

He joined the Literary and Philosophical Society in 1873 and served on the Council for many years, acting as President to that Society from 1917–19. The Society is richer for his many contributions on different subjects of scientific interest, some of which during his lifetime developed into discoveries of supreme and world-wide renown. Only in November of last year he presented the actual tubes containing sulphides of calcium, barium, etc., which he demonstrated to Sir Wm. Crookes in 1877, and which proved to be the first of three steps which led to the discovery of X-rays by Prof. Röntgen. He presented some of these sulphides to Wm. Crookes, who wrote on February 13, 1879, as follows :—

" When I had the pleasure of seeing you in Manchester about a year ago you kindly gave me some specimens of highly phosphorescent powders. I have lately been working on the electrical phenomena in very high vacua, and I have found great use from these powders, as their great luminosity enables me to examine the phenomena I am studying without difficulty. Unfortunately, I have used up all the stock you gave me, and am obliged to come to you to ask if you can spare me a little more, or, what would be better, let me know how to prepare some myself, and then I would not trouble you."

Again, on March 26, 1879, Sir Wm. Crookes wrote :—

"Accept my thanks for the phosphorescent powder; it is invaluable for my researches, as it has wonderful power of glowing under the influence of the molecular discharge."

A third letter dated April 28, 1897, is as follows:—

" My dear Prof. Thomson,—I was much interested in reading a copy of our correspondence in 1877–1879. It takes one back to the very beginnings of my Radiant Matter experiments and Phosphorescence in high vacua, which has been so splendidly carried on by Lenard and Röntgen. When I have occasion to write anything about the early history of the X-rays, it will be very useful to have these letters to refer to, and I will not fail to mention the part you played in the progress of the research, when you drew my attention to the phosphorescing properties of the sulphides of calcium. With kind regards, believe me, very sincerely yours,

"William Crookes"

His numerous and various chemical and physical investigations can only be dealt with, however, in scientific journals, but his medico-chemical and legal work is known to many specialists in Manchester. A few weeks ago he prepared some material which he hoped would be found of assistance in the cure of cancer. His work is also known on the detection of arsenic in beer during the outbreak of arsenical poisoning some years ago, and his indefatigable and original work on the amount of soot in the smoke-laden atmosphere of Manchester and, in association with the Manchester and Salford Sanitary Association, his efforts to obtain a purer atmosphere should be a memorial to him among the public of this city.

In recognition of his many original contributions to science he was elected a Fellow of the Royal Society of Edinburgh, May 1, 1876.

He was also the author of a book on *The Sizing of Cotton Goods*, of which the first edition was published in 1877 and the second in 1879.

Mr. Thomson was one of the original members of the Society of Chemical Industry. He was elected to the committee in October, 1884, and acted as the Chairman of the Manchester Section for some years.

He was also one of the leading forces in the Institute of Chemistry, of which he was elected a Fellow in 1877, and served on the Council from 1887–90 and from 1893–96. For some years also he was on the committee of the Society of Dyers and Colourists.

There was a quiet reticence about him which prevented many from ever visioning his many-sided genius and rich and sympathetic nature, but those who were privileged to know him in private life knew a just and generous man, and his charitable acts will never be revealed.

He was past-president of the Caledonian Association, and interested in the Burns-Scott Fund as Chairman of the Committee.

The writer has heard from many lips during the last few days the following remark, which seems to epitomise his whole character:—"He was the dearest friend I ever had or ever shall hope to meet." His death is an irreparable loss to the City.

The Salters' Institute of Industrial Chemistry has awarded 64 grants in aid to chemical assistants, occupied in factory or other laboratories in or near London, to facilitate their further studies.

FORTHCOMING EVENTS

Oct. 30. Society of Chemical Industry, *Edinburgh and East of Scotland Section*, in the Hall of the Pharmaceutical Society, 36, York Place, Edinburgh, at 7.30 p.m. "Old and New Problems in Agricultural Chemistry," by Dr. A. Lauder. "Galegine, an Alkaloid from *Galega officinalis*," by Dr. F. D. White.

Oct. 31. Society of Chemical Industry, *Newcastle-on-Tyne Section*, the Chemical Lecture Theatre, Armstrong College, Newcastle, at 7.30 p.m. "Milk," by H. R. Whitehead, M.Sc.

Nov. 1. The Institution of Electrical Engineers, The Lecture Theatre, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "Industrial Research, with special reference to Electrical Engineering Development," by W. Wilson.

Nov. 2. The University of London, University College, Gower Street, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science" (Lecture I.), by Prof. G. Dawes Hicks. Also on the 9th, 16th, 23rd, and 30th.

Nov. 2. The Institute of Chemistry, *Manchester and District Section*. Joint Meeting with the Society of Chemical Industry, of Dyers and Colourists, and the Manchester Literary and Philosophical Society, in the Textile Institute, Manchester, at 7 p.m. "Electrometric Methods in Analytical Chemistry," by Prof. Treadwell.

Nov. 5. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 7 p.m. "Engineering Training." Discussion to be opened by Dr. A. Russell, M.A.

Nov. 6. Institution of Civil Engineers, Great George Street, S.W. 1, at 6 p.m.

Nov. 7. Society of Public Analysts. Ordinary Meeting at Burlington House, Piccadilly, W. 1, at 8 p.m.

Nov. 8. Institute of Metals, *London Local Section*, The Royal School of Mines, South Kensington, S.W. 7, at 8 p.m. "Some Impressions of American Non-Ferrous Metallurgy," by W. Rosenhain, D.Sc.

Nov. 8. Society of Chemical Industry, *South Wales Section*, The Engineers' Institute, Park Place, Cardiff, at 7.30 p.m. "The New Chemistry," by Dr. E. F. Armstrong, F.R.S.

Nov. 9. Institute of Metals, *Sheffield Local Section*, The University, St. George's Square, Sheffield, at 7.30 p.m. "Substitutes for Platinum," by E. A. Smith, A.R.S.M.

Nov. 9. The University of London, University College, W.C. 1, at 5.15 p.m. "Vitamins," by Prof. J. C. Drummond.

Nov. 9. The University of London, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science," by Prof. G. Dawes Hicks. (Lecture 2.)

SOCIETY OF CHEMICAL INDUSTRY

DINNER OF CHEMISTS,

October 31, 1923

As we have previously announced, a dinner of Chemists is to be held next week under the joint auspices of the Chemical Society, the Institute of Chemistry, and the Society of Chemical Industry. The arrangements for the dinner, which will take place in the Edward VII Rooms, Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Wednesday, October 31, at 7 for 7.30 p.m., have been made by a committee representing the above Societies and certain other Societies as well.

Sir William J. Pope, K.B.E., F.R.S., has consented to take the chair and the committee now announces that a limited list of toasts has been arranged and that a short musical programme will be presented by Mr. Ivor Foster and Miss Megan Foster, both well-known on the concert platform.

This is the first dinner of its kind to be held for chemists, and as nothing has been neglected that will make the evening attractive, it is hoped that a large and representative gathering will be present and thus ensure success. It is especially to be noted that there will also be opportunities for social intercourse, a feature of great value in view of present aspirations.

Members of any of the participating Societies are invited to attend and bring guests, including ladies. The price of tickets is 12s. 6d. each, not including wine, and applications (accompanied by the appropriate remittance) should be sent *immediately* to the General Secretary, Society of Chemical Industry, Central House, Finsbury Square, London, E.C. 2.

Applicants are invited to state the names of friends, beside whom they wish to be seated and to furnish the names of their guests.

LIST OF MEMBERS ELECTED

October 12, 1923

Atsuki, Katsumoto, Dept. of Applied Chemistry, Faculty of Engineering, Tokyo Imperial University, Tokyo, Japan. Professor.
Board, T. F. Anthony, 13, Cornwallis Crescent, Clifton, Bristol.
Bowker, Frederic C., 20, Hawcoat Lane, Barrow-in-Furness. Analytical Chemist.
Burke, Dr. Stephen P., c/o Combustion Utilities, Corporation, 125, Van Dam Street, Long Island City, N.Y., U.S.A. Chemical Engineer.
Carpenter, Leonard, c/o The Derbyshire Silica Firebrick Co., Ltd., Friden Station, Hartington, nr. Buxton, Derbyshire. Chemist.
Carter, John F., Elizabeth, Louisiana, U.S.A., Chemical Engineer.
Cooper, Francis J., 45, Berw Road, Tonypandy, Glam., South Wales. Manager of Coke and By-products Works.
Cripps, Charles V., West Bank, Widnes, Lancs. Analytical Chemist.
Davis, Jack B., c/o The Standard Textile Products Co., 320, Broadway, New York City, U.S.A. Technical Engineer.
Elford, William J., 35 Northumberland Road, Redland, Bristol. Student.
Frith, James S., Ascog, Thelwall, near Warrington. Works Chemist.
Goring, Arthur W., Messrs. Wm. Barbour and Sons, Ltd., Hilden, Lisburn, Ulster. Textile Chemist.
Henry, James, Burmah Oil Co., Ltd., P.O. Box 67, Rangoon. Petroleum Chemist.
Heppell, S. Bulmer, British Cellulose and Chemical Co., Ltd., Spondon, near Derby. Chemical Engineer.
Hogan, George, 69, Dock Street, Newport, Mon. Chemist.
Hughesdon, Reginald S., Australian Fertilizers Pty., Ltd., Port Kembla, N.S.W., Australia. Chemist.
Lancaster, Roy, c/o Mrs. Smith, 161, Merton Road, Wimbledon, London, S.W. 19. Analytical Chemist.
Langdon, Guy M., Dunwood, Uphill, Weston-super-Mare. Student.
Lewis, Essington, c/o The Broken Hill Pty. Co., Ltd., 320, Collins Street, Melbourne, Victoria, Australia. General Manager.
Lyon, Joseph, 14, Storey Square, Barrow-in-Furness, Lancs. Analytical Chemist.
Marsh, Eric R., 14, Sheen Gate Gardens, East Sheen, London, S.W. 14. Chemical Engineer.
Maxwell, Stanley C., 36, Grange Park, Ealing, London, W. 5. Engineer.
Muir, Robert I., c/o Creamola Food Products Ltd., 54, Great Clyde Street, Glasgow. Chemist.
Muspratt, Rudolph, St. John's College, Oxford. Student.
Naidu, D. Satyanarayana, Indian Institute of Science, Hebbal, Bangalore, India. Research Student.
Osmond, Donald A., 13, Southside, Weston-super-Mare. Student.
Penny, Thomas, 11, Devonshire Road, Westbury Park, Bristol. Soapery Manager.
Reynolds, Herbert F, "Cooroona," 12, Proctors Road, Hobart, Tasmania. Chemical Engineer and Metallurgist.
Richards, William G., Morro Velho, Nova de Lima, Minas Geraes, Brazil. Industrial Chemist.
Sapojnikoff, Alexis, Zabalkansky pr. No. 9, Petrograd, Russia. Professor of Chemistry.
Smart, John, Minerals and Metals, Ltd., 4, Lloyd's Avenue, London, E.C. 3. Analytical Chemist.
Warr, John C., 11, Cavendish Road, Henleaze, Bristol. Chemist.
Whitworth, Dr. Abraham B., 42, Murray Road, Rugby. Chemist (B.T.H. Lamp Works).
Williams, Evan C., Ramsay Memorial Laboratory, University College, Gower Street, London, W.C. 1. Professor of Chemical Engineering.
Wilson, Donald M., Highways Construction, Ltd., Point Pleasant, Wandsworth, London, S.W. Chemist.
Wright, Gerald S., 2, Wharncliffe Villas, Sunny Bank, Sheffield, Yorks. Brewery Chemist.

NOTTINGHAM SECTION

The opening meeting of the Session was held on October 17, when the chairman, Mr. J. M. Wilkie, read his address entitled: "Some reflections on the importance of Chemistry to the Community and the means which should be adopted to bring the fact home to the 'man in the street.'"

Not until the outbreak of war was the importance of chemistry realised by the community. During the war, informative and often eulogistic articles, appeared quite frequently in the Press upon the fine work performed by chemists. Since the war, however, the Press rarely and scantily referred to the importance of chemistry or to the strenuous efforts of chemists in pursuing vital investigations. To illustrate the importance of such investigation Mr. Wilkie discussed the direct relationship between dietetics and deficiency diseases such as scurvy. The systematic study of the effect of various vitamins would ultimately be of the greatest benefit to the human race.

Another most important problem to be solved by the chemist was the exhaustion of the soil. Supplies of nitrogenous fertilisers were now assured by the synthesis of nitrates, but a very different state of affairs existed with regard to potash and phosphates, ultimate supplies of which were limited. Until we found some means of replenishing the natural stocks of such things, we were foolishly "living on capital."

If such questions as these could be placed frequently before the public, the importance of chemistry in attacking such problems would be brought home. The trouble nowadays was to get the Press to realise that discussion of such things is at least as important as long descriptions of sports.

In conclusion the speaker referred to the efforts which were being made to make the *Journal* more interesting and attractive, so that it would appeal to people outside the chemical profession.

Mr. H. Droop Richmond in opening the discussion, asked if the Society of Chemical Industry was doing all it could to further the importance of the chemical profession. He thought not, and considered that insufficient publicity was being given either to the meetings or the *Journal* itself. He rather deprecated the introduction of too much merely interesting and amusing matter, rather than the solid scientific material of bygone years. He also considered that articles in the *Journal* appealed rather to the production departments of manufacturing establishments than the sales departments which were of more importance to the advertiser.

Mr. Pentecost agreed with Mr. Richmond and thought that the *Journal* of ten to twenty years ago was of much greater interest than that of the present day. He recommended the omission of the weekly "Trade Report," which he thought was of but little interest for most members. Greater publicity of the work of the chemist would be obtained if reports of meetings were published in other journals.

Mr. Burford described the popular idea of a chemist who was supposed to be one of three things—a wizard, a detective, or a money maker (for his employer). The schools were the starting place for educating the public as to what a chemist really did, and the Press also could do a great deal in making the ordinary layman familiar with the methods and aims of chemistry.

Dr. Firth considered the *Journal* much improved as it differed from many others in being very readable, and therefore it had an attraction even for the outsider; the subject matter in "lighter vein" was a distinctly advantageous feature.

Mr. Barker stated that personally he found the weekly market report of considerable advantage.

Mr. Dunford agreed and said that these reports were especially useful for back reference. He thought that extension of the popular lecture would be beneficial in bringing the public into closer understanding as to what chemistry was. He mentioned his appreciation of the lighter articles in the *Journal*.

Dr. Prideaux said that chemistry possessed a distinctly cultural value. Although the chemical profession consisted of a large body of men of many varied attainments, recognition of such a body would only come when internal schisms and strife ceased. Chemistry in the elementary school had suffered a retrograde movement in being gradually eliminated from the curriculum.

Messrs. Povey, Mayfield and Meek likewise expressed the importance of starting with school children as a first step in bringing home the importance of chemistry.

Dr. Firth and Mr. Higson read a paper describing the action of aqueous sodium hyposulphite (hydrosulphite, $Na_2S_2O_4$), upon silver chloride. The reaction with solid silver chloride at ordinary temperatures was very slight (using hyposulphite solutions up to 6 per cent.) and the main product was silver sulphide. For higher concentrations of hyposulphite, increased action occurred up to a temperature of 50° C., when silver sulphide and metallic silver were produced.

When a solution of silver chloride in sodium thiosulphate was treated with hyposulphite solution the product was entirely silver sulphide, quantitatively precipitated. Silver chloride dissolved in an excess of ammonia solution was rapidly and quantitatively reduced to metallic silver when treated with hyposulphite.

Finally, a similar quantitative reduction to finely divided metallic silver occurred when a solution of silver nitrate in excess of ammonium hydroxide solution was acted upon by hyposulphite solution. The quantitative precipitation of silver sulphide from the thiosulphate solution of silver chloride, and of metallic silver from the ammonium hydroxide solution afford two convenient methods for the recovery of silver from silver residues, as both the silver sulphide and finely divided metal were readily converted into silver beads by lightly fusing.

Mr. Burford, Mr. Lambourne and Dr. Prideaux commented upon the possibilities of a simple and economical recovery of silver from silver residues in the light of the above results. Mr. Prince inquired whether the cost of the formerly unfamiliar sodium hyposulphite would render the recovery of silver from residues unproductive. Mr. Wilkie asked whether silver residues containing a mixture of chloride bromide and iodide could be economically treated. Dr. Firth, in reply, stated that sodium hyposulphite was now a commercial article, and that a mixture of the three silver halides could probably be extracted with sodium thiosulphate and subsequently precipitated.

CHEMICAL SOCIETY

At an ordinary meeting held on Thursday, October 18, 1923, at 8 p.m., the President, Prof. W. P. Wynne, F.R.S., occupied the Chair.

An important announcement was made which concerned the future of the Abstract section of the *Journal*. Arrangements had been made whereby the publication of abstracts of papers in the domains of pure and of applied chemistry would be directed as from January next by a Bureau consisting of representatives of the Chemical Society and of the Society of Chemical Industry. The members nominated by the former are Prof. W. P. Wynne, F.R.S., (President), Prof. J. F. Thorpe, F.R.S., (Treasurer), Dr. Irvine Masson (one of the Secretaries), and Prof. G. T. Morgan, F.R.S. The Bureau would co-opt a ninth member as Chairman, and would then proceed immediately to examine the position with a view to unifying the abstracts hitherto prepared separately by the two societies, apportioning the cost, and thereby effecting substantial improvements and economies. In the meantime, however—certainly until the end of next year—no change in the present format or method of preparing the abstracts was contemplated, apart from that announced at the last meeting.

Dr. C. K. Ingold gave an account of

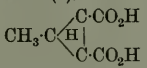
The chemistry of the glutaconic acids. Part XV. Three-carbon tautomerism in the cyclopropane series. Part 2. By F. R. Goss, C. K. Ingold, and J. F. Thorpe.

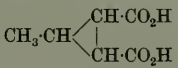
The study of the isomerism of a glutaconic acid, in which the possibility of geometrical isomerism is excluded by ring formation is of interest, because, in such a case, the evidence is clearer than any which has previously been obtained, that in three-carbon tautomerism structural conditions may be encountered which cannot be interpreted by conventional space models.

Further experimental evidence is now brought forward that the tautomeric relationship of the three isomeric esters of the cyclic glutaconic acid (I) is such that after the mobile hydrogen atom has passed into the carboxyl group, as in the enol-ester, it cannot return to the position which it takes up in the normal ester directly, but only by way of its position in the labile ester, that is, on the α-carbon atom of the system, which forms a halting place in the two stage migration.

In view of the apparent impossibility of reducing the acid (I) to the saturated cyclopropane acid (II), the converse process has been studied. The acid (II) has been isolated in each of its three possible stereoisomeric modifications, and a double bond has been introduced into each by more or less conventional methods. In each case the product is the acid (I).

(I)





(II)

The President commented on the authors' skill in obtaining the three definite crystalline isomers from a viscous mass, whereby it was possible to complete the investigation.

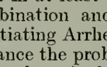
Mr. R. G. W. Norrish dealt with the effect of a containing surface on chemical reaction, as follows :—

Studies of electrovalency. Part III. "The catalytic activation of molecules and the reaction of ethylene and bromine." R. G. W. Norrish.

The hypothesis is advanced that molecular activation is at any rate partly a catalytic process consisting in the polarising of the reactant molecule by association with the molecule of a polar catalyst, either in a gaseous, surface, or liquid phase. This is supported by the fact that complete desiccation of reactants suspends reaction in the great majority of the cases investigated. Lowry's view that the molecules of unsaturated organic compounds which are unreactive in their resting form may become reactive by developing an electrovalance in the double bond—*e.g.*, by contact with some polar substance (gaseous or otherwise), is a special form of this hypothesis in which the complete ionisation of the bond is postulated. The hypothesis is tested experimentally by investigation of the reaction of ethylene and bromine. It is shown that the dried gases practically cease to react when enclosed by "non-polar" walls of paraffin wax, but that they react rapidly when enclosed by a "polar" surface of glass, stearic acid or cetyl alcohol. The reactivity of the gases as measured by the bimolecular velocity constant varies with the chemical nature of the enclosing surface, being greatest for stearic acid—the substance which may be considered the most polar of those investigated. On passing dry ethylene and bromine, diluted with air, through a paraffined tube, and then through a glass tube, no ethylene dibromide was observed in the paraffined tube, while about ·3 gm. collected in the glass tube. These results are considered as evidence in favour of the contention that molecular activation is normally associated with a process of catalytic polarisation.

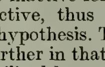
Dr. J. Kenyon asked whether all the bromine was known to react with the ethylene, to the exclusion of the formation of bromostearic acid.

Dr. E. K. Rideal said that the investigations on the "activation" of ethylene by a polar surface indicate that the ethylene molecule can exist in at least two forms, one inactive for the combination and the other active, thus substantiating Arrhenius' original hypothesis. They advance the problem a stage further in that the active form is shown to be stabilised by a polar substance, and must therefore itself be polar. Lowry suggests that the active or polar form is Thomson's intramolecularly ionised form; it is possible, however, that there exist between the symmetric non-polar form and the completely ionised form not only one (intramolecularly ionised) state of the ethylene molecule, but several of different degrees of polarity, corresponding with the various possible quantic orbital rotations of the binding electrons. Gaseous ethylene may consist of a mixture of molecules in the various quantic states, and the catalyst may operate by stabilising one state by means of association; alternatively, the catalyst may actually raise the quantic state of an adsorbed molecule by means of its powerful field. In a non-symmetrical molecule two forms of the active state may be envisaged (I and II), to which we may give the term electro-isomers; these will add on a polar molecule, *e.g.*, $\overset{+}{H}\overset{-}{Br}$ to form different compounds. The saturated bromide on dissociation into the unsaturated hydrocarbon and hydrobromic acid would at the moment of dissociation be polar; but on cooling, recombination to form both bromides would take place, *i.e.*, the polar form does not persist, but relapses into the resting or non-polar state.



$$\begin{matrix}H\cdot C\cdot CH_3+\\ |\\ CH_2\quad -\end{matrix}$$

(I)



$$\begin{matrix}H\cdot C\cdot CH_3-\\ |\\ CH_2\quad +\end{matrix}$$

(II)

From what had been said by Dr. Ingold, it would appear to be possible, in Dr. Rideal's view, that the degree of activation or the degree of polarisation in a molecule necessary to produce interaction with another substance varied with the reaction. Activation apparently increased the magnetic moment of a molecule, and experiments in the intense magnetic fields recently made possible by a device of Mr. Capitzlea in the Cavendish Laboratory might yield interesting results.

Prof. T. M. Lowry, F.R.S., remarked that further experimental work in a similar direction was in progress.

Dr. Irvine Masson, congratulating the author on his suggestive and very interesting facts, enquired to what extent they might be explicable on Langmuir's hypothesis concerning surface catalysis. According to this "fly-paper" hypothesis, the molecules of one reactant, pinned down on the solid in patches or sheets to a varying extent, and oriented favourably for the impact of those of the other, were the seat of the reaction; was this not operative here, where it might then be unnecessary to import any further hypothesis as to the existence of free activated molecules in the gas?

Replying, Mr. Norrish said that the behaviour of ethylene and bromine separately had been examined in coated vessels; with the former, no effect had been detected, whereas with the latter the slight absorption corresponded with an error in the main experiments of not more than 1 per cent. The colour of the bromine persisted when the mixture was contained in a paraffined vessel, but disappeared almost immediately when other coatings were used. He considered that Langmuir's surface catalysis hypothesis was insufficient since it would involve an expectation of some reaction taking place in the gaseous mixture; further, the reacting molecules, even if they were pinned down, must be altered so as to be in some intrinsically more active form.

Mr. R. R. Le G. Worsley read a paper entitled:

Selenium trioxide and chlorselenic acid. By R. R. Le G. Worsley and H. B. Baker.

MANY attempts have been made, without success, to obtain the selenium analogue of the trioxides of sulphur and tellurium, both by direct union of oxygen with the element and the oxide, and by dehydration of selenic acid. The action of ozone on dry selenium had already been shown to produce only the dioxide, but by the use of a solvent this agent has carried the oxidation a stage further and selenium trioxide has been isolated. The solvent used was the oxychloride of selenium, which when alone was found to be unaffected by ozone. The solution of selenium in the oxychloride showed little or no apparent change by treatment with 7% ozone for 30 hours, but after this the trioxide separated out in considerable quantity. Analysis showed 62·01% of selenium, SeO_3 requiring 62·26. The molecular weight by lowering of the freezing point of phosphorus oxychloride was found to be 136. Selenium trioxide is a very pale yellow powder of density 3·6. It decomposes at 120° without melting or subliming. It dissolves in water with evolution of heat, but is insoluble in ether and other common solvents. It combines directly with dry hydrogen chloride producing chlorselenic acid, which is found to be very similar to chlorsulphonic acid. Analyses and molecular weight determinations confirm the existence of the new acid.

The President remarked on the interesting fact that the new oxide had not been found to polymerise.

Dr. C. K. Ingold summarised the following paper :—

The chemistry of polycyclic structures in relation to their homocyclic unsaturated isomerides. Part V. Orientation in the gem-*dimethyl*dicyclo*pentane series.* R. C. Grimwood, C. K. Ingold, and J. F. Thorpe.

The proof adduced by recent experiments that derivatives of dimethyl*cyclo*pentadiene (I) are tautomeric with corresponding derivatives of dimethyl*dicyclo*pentene (II), and that the nucleus of each substance of the series possesses two distinct phases which together confer on the compound a dual chemical character, raises certain problems of structure, principally relating to the orientation of attached groups, which require special methods for their solution.

(I) 
 (II)

Thus there are two positions in which the sodio-ester (III, IV) might methylate on carbon; namely, position (4) through the operation of the β-ketonic ester residue derived from $CO_2Et{\cdot}\underset{(4)}{\overset{|}{C}} : \underset{(3)}{\overset{|}{C}}{\cdot}ONa$ in (III) and position (2) through the β-ketonic ester group derived from $\underset{(3)}{\overset{|}{C}}(ONa) : \underset{(2)}{\overset{|}{C}}{\cdot}CO_2Et$ in (IV). The product should therefore have either formula (V) or formula (VI), and in either case, since the nucleus cannot now revert to the quasi-aromatic structure (types I or II), intra-annular tautomerism must be suspended, and the substance should be capable of being orientated as a static individual.

(III) 
(IV) 
(V) 
(VI) 
Experiment showed that the substance has formula (VI), methylation having fixed the tautomeric nucleus in its bridged modification.

SOCIETY OF GLASS TECHNOLOGY

The first meeting of the session was held in Sheffield on October 17, the president, Prof. W. E. S. Turner, D.Sc., in the chair. "Frank Wood" medals were presented to Mr. A. R. Sheen, B.Sc.Tech., and Mr. F. Winks, B.Sc.Tech. by Sir W. H. Hadow, vice-chancellor of the University of Sheffield.

It was resolved to send a cordial invitation for a conference in this country sometime during 1924, jointly to members of the Society in France and to the Chambre Syndicale des Maîtres de Verreries (the representative body of French manufacturers which had welcomed the party to Paris in July).

A paper entitled "The Effect of Titania on the Properties of Glass," by A. R. Sheen, B.Sc.Tech., and Prof. W. E. S. Turner, D.Sc., was read by Mr. Sheen. In presenting this paper Mr. Sheen remarked that a great deal of interest had recently been shown in the production of heat-resisting glass. Manufacturers, especially of scientific glassware, were realising the necessity of making a glass which had a high thermal endurance and which at the same time was resistant to the attack of solid, liquid or gaseous substances. Modern heat-resisting glasses contained a high percentage of silica and also boric oxide in considerable amount. There were, however, objections to the use of these oxides. With silica the difficulty was merely that of obtaining a sufficiently high melting temperature. Glasses containing boric oxide were readily melted, however, but here the objection was the effect of the oxide on the durability of the glass. As the B_2O_3 content of a glass increased the durability towards water and acid rose to a maximum, but when the B_2O_3 content was further increased, the durability fell off rapidly. It seemed that titania glasses were heat-resisting, but no experimental data were available. It was with this consideration specially in mind that this piece of work was undertaken.

At the outset preliminary tests were made to find out what mixture of silica, titania and soda would give glasses at the highest temperature obtained in glass melting practice, *e.g.*, temperatures of 1400° to 1450° C. It was found impossible to obtain a glass from silica and titania alone at this temperature. Batches were then calculated out on the basis of the glass formula :—

$$6\ SiO_2\ xNa_2O\ yTiO_2 \text{ where } x+y=2.$$

and it was found that the first six members of the series gave glasses quite readily, *i.e.*, glasses of the approximate molecular compositions :—

(1) $6\ SiO_2\ 1{\cdot}9Na_2O$; $0{\cdot}1\ TiO_2$.
(2) $6\ SiO_2$, $1{\cdot}8\ Na_2O$, $0{\cdot}2\ TiO_2$.
etc., etc., etc.
(6) $6\ SiO_2$, $1{\cdot}4\ Na_2O$, $0{\cdot}6\ TiO_2$,

in which the soda was gradually replaced by titania. Above 1·8 mol. TiO_2, *i.e.*, 13 per cent. TiO_2, it was found increasingly difficult to melt the glass and higher temperatures were required. If these glasses were melted under reducing conditions, their colour varied from light amber to dark brown. Therefore part of the soda content was added as soda nitre and the melting operation was carried out in crucibles with well-fitting lids. By this means colourless glasses were obtained. There were indications during these melting operations that titania glasses were heat-resisting. It was found in many cases that the glass could be removed straight from the furnace and allowed to cool down in the open air without splintering or cracking of the mass of glass occurring.

It was found on comparing with the corresponding lime and magnesia glasses that the titania glasses were less attacked by water than the lime glasses, especially in the earlier members of the series. The durabilities of the titania glasses were found to be practically the same as those of the corresponding magnesia glasses. The annealing temperatures were found to be rather less than those of the corresponding lime and magnesia glasses. The melts were repeated on a large scale (28 lb. pot), tubing was drawn and the expansion determined by the ordinary dilatometer method. The thermal expansions of the first four titania glasses were only slightly less than those of the corresponding lime glasses. Therefore, if titania glasses were heat-resisting this was not due to their low expansion, as was the case with Pyrex glass, but to some other factor such as tensile strength or elasticity.

These glasses possessed good working properties, their viscosity increasing as titania replaced soda. Throughout all the glasses melted in connexion with this work there was hardly any evidence of devitrification occurring. This bore out the statement of previous workers that titania hindered devitrification.

Mr. A. Cousen, B.Sc., A.R.C.S., then gave a paper entitled, " The Estimation of Selenium in Glass." Illustrating his remarks with experiments, Mr. Cousen said that during the course of researches on the use of selenium as a decolorising agent it was found desirable if possible to obtain a method for the estimation of selenium in the glasses obtained. The amount of selenium actually added to the batch was, in general, sufficient to give only 1 part of the element per 42,000 parts of glass, or 0·0024 per cent., if no loss occurred. But as selenium was volatile at the furnace temperature (the boiling point at 1 atmosphere pressure was 680°), considerably smaller values were likely to be found. The only chemical method for estimating selenium in glass so far published was that of Fränkel and described by Witt (*Sprechsaal*, 1914), and this was not quite comparable since it dealt with proportions of selenium at least ten times as great as those it was desired to estimate. The following modification of the above process was found to give results of fair accuracy. Twenty grams of finely powdered glass was dissolved slowly in hydrofluoric acid, and after standing in the cold the products of decomposition, with the exception of selenium, were dissolved by pouring into excess of boiling water. The selenium itself was filtered off on a filter pulp pad in a Gooch crucible. From the pad the selenium was removed by treating with a dilute chlorine solution (about 1/300 N). To the filtered solution was added 1 c.c. of 5 per cent. gum arabic and 5 c.c. of 0·5 per cent. phenylhydrazine hydrochloride, the whole being made up to 50 c.c. Colloidal selenium was obtained, a yellow colour slowly developing, which after half an hour was matched against a standard solution of sodium selenite similarly treated. The method on testing with synthetic mixtures gave results well within 0·0002 per cent. of the actual values and a commercial glass, for which sufficient selenium had been used to give, theoretically, 0·0025 per cent., was found to contain actually only 0·0006 per cent. of the element.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

A meeting was held recently in the Lecture Theatre of the Chemical Department, with Prof. G. T. Morgan, F.R.S., in the Chair. Prizes for work during the past Session were presented by Prof. A. R. Ling, who afterwards gave an address on " Some Recent Advances in our Knowledge of the Chemistry of Starch."

Dealing with the historical portion of the subject, Prof. Ling paid a high tribute to the work of the late Cornelius O'Sullivan and to that of Dr. Horace T. Brown, remarking that these pioneer workers had furnished methods whereby advances had been made in solving the problem of the constitution of starch.

According to Maquenne and Roux and Mme. Gatin-Gruzewska, starch granules consist of two substances, amylo-cellulose, or amylose, the inner portion, which is soluble in water and gives a clear blue coloration with iodine, and amylopectin, the outer portion, which gives a viscous paste when heated with water. Ling and Nanji have found that when starch paste is kept in a mixture of salt and ice for several hours the starch is precipitated as a fibrous mass resembling a wad of moist cotton wool. After this mass has been brought to the ordinary temperature the amylose may be extracted from the amylopectin by washing with water at a temperature just below the gelatinising point of the starch employed. Amylopectin gives a viscous paste when heated with water, and if to the cooled paste iodine solution is added a bluish-black precipitate is produced. Amylopectin as it exists in the granules is a phosphoric ester, and it is suggested that the conversion of potato starch granules into soluble starch by treatment with 7 per cent. hydrochloric acid at ordinary temperature, according to Linter's method, consists in the hydrolysis of this ester and the removal of phosphoric acid. Morphologically there is no difference between potato starch granules and soluble starch. When amylopectin is acted on by ungerminated barley it is partially depolymerised and converted into the substance obtained by J. L. Baker in 1902 and called by him α-amylodextrin. This substance has been obtained devoid of reducing properties, and in solution gives a pure blue coloration with iodine. When either amylopectin or Baker's dextrin is treated with malt extract at 70° until the iodine reaction just disappears, it is converted into a hexatriose which is shown to be α-glucosidoisomaltose or β-glucosidomaltose,

$$C_6H_{11}O_5\underset{\alpha}{—O—}C_6H_{10}O_4\underset{\beta}{—O—}C_6H_{11}O_5,$$

which has a specific rotatory power of $[\alpha]_D$ 165° and reducing power, in terms of maltose as 100, of R=66. It is an amorphous, highly hygroscopic powder, melting at 202—203°. It forms a definite crystalline phenylosazone of melting-point 122°. Treated with malt diastase or maltase at 55° it is converted into isomaltose and glucose, whilst treated with the β-enzyme of almonds it is converted into maltose and glucose. Isomaltose is shown to have the properties described by Lintner. It is an amorphous powder somewhat less hygroscopic than the hexatriose. Its specific rotatory power is $[\alpha]_D$ 140° and its reducing power R=80. It is unfermentable by ordinary *Saccharomyces cerevisiæ*. Isomaltose when treated with the enzyme of almonds is converted into two molecules of glucose.

Ling and Nanji accept the view of Pringsheim, Karrer and Irvine, that starch consists of polymerised non-reducing substances to which Pringsheim has given the name amyloses. The basal unit of polymerised amylose is α-hexa-amylose, and this consists of three condensed diamylose residues. It is quantitatively converted into maltose by diastase of ungerminated and germinated grain. The basal unit of amylopectin is α-β-hexa-amylose, and this consists of two β-diamylose residues and one α-diamylose residue. Treated with precipitated malt diastase at 70°, it is converted into two molecules of β-glucosidomaltose. Treated with malt extract at 55° it yields two molecules of isomaltose and one of maltose. Maltase converts it into two molecules of isomaltose and two molecules of glucose.

It has recently been shown by S. B. Schryver that certain of the starches contain hemicellulose complex, and Ling and Nanji have confirmed this. In agreement with Schryver, they show that the starches of potato and arrowroot consist entirely of polymerised amylose and amylopectin.

CORRESPONDENCE

ELLIS'S PRACTICAL BACTERIOLOGY FOR CHEMICAL STUDENTS

Sir,—Here's a pretty kettle of fish! A chemical journal asks a medical man to review a book for chemists, written by a biologist. The medical man sets about it with gusto and spices his review with a tinge of malice. Before dealing in detail with Dr. Renshaw's review I must, at the outset, present one of my chief credentials, namely, that my book was written after the precepts and rules laid down in it had been put into practice in the teaching of chemists for a period of eighteen years. Imagine a young chemist deposited in a factory and having to tackle some trouble that has arisen owing to a microbe having run amuck in the works. What does he need in the way of bacteriological instruction to tackle a situation of this kind? My book set down what I had found by experience to be possible in a first course of this kind. Your reviewer has not the imagination to see this. In his mind's eye he envisages only that particular brand of bacteriologist that is turned out in medical laboratories.

Some of the objections raised by him are truly puerile. Suppose I did cite *Cladothrix dichotoma* as an organism which stored glycogen. What then? This organism is extremely important in industrial bacteriology, and its depredations in other countries have called Royal Commissions into being. Apart from that why mention such a trivial feature, which occupies one line in the book, as a reasonable ground for objection to the book as a whole? Again, why bother about the insertion of a diagram of an Erlenmeyer flask? Even Dr. Renshaw does not appear to be able to spell the name correctly. His utter lack of comprehension is shown in his objection to the prominence given to *Bac. megatherium*. He says it is an organism which is not of "great consequence." I will supplement that by stating that it is of no consequence whatever. What is of consequence is its extreme usefulness for use in *inculcating the principles of Bacteriology*. It is a giant of its kind, a prince in its own country, and that prince can be got from the Lister Institute for the sum of 1s. It forms spores, it exhibits motility, and develops solid reserve materials. It is an ideal organism for teaching purposes, but note the comment: "It is not of great consequence in routine bacteriological work."

Then, again, I am indicted for not including ultra-microscopic methods of examination and other branches of bacteriological work. What does he expect? My object was to write an introductory text-book, not an encyclopœdia. I aimed at the housetops and he blames me for not striking the moon. I hesitated before finally rejecting the bacteriological treatment of disinfectants, but even this had to go owing to the imposed limits of the book. It is difficult to deal seriously with the statement that a coccus is scarcely visible when magnified 350 times. The average coccus is 1 μ in diameter; when magnified to this amount its magnitude = 350 μ = ·35 mm. Does it need an "optimist" to work with cocci magnified to this extent?

Again, exception is taken to the lack of finish of my cultures, and to priority of place of gelatin cultures. Incidentally, these are given not priority, but equality of place. Does it not occur to Dr. Renshaw that this might have been done purposely? The media as prepared in my laboratory will secure the development of 99·9 per cent. of all the organisms that the works' chemist is likely to meet, and, after all, the proof of the pudding is in the eating. I find gelatin-media not only useful but necessary for the particular class of work for which this book was written. If Dr. Renshaw thinks otherwise from his experience of this aspect of bacteriology, he is welcome to his opinion. All the other points, with two exceptions, are like the above, either counsels of perfection or else superficial nonsense. The two exceptions are the omission of the counterstain in Gram's stain, and the omission of two diagrams, to which he did right to call attention. These omissions were the results of a pure accident.

The plain fact of the matter, Sir, is this, that throughout the whole of this review Dr. Renshaw is judging the book according as it is going to be helpful or otherwise to a person wishing to undergo the routine work of a medical bacteriological laboratory. Whatever may be the merits or demerits of the medical training it is quite useless for the student of chemistry, who must be taught the foundations of the subject; and this can only be accomplished by approaching the subject from the biological side. An intensive study of pathogenic organisms may necessitate an approach of the subject in a purely empirical manner, but I must protest when obstructive criticism is levelled at my book because your reviewer has not the imagination to project his mind to the requirements of the works' chemist, who must be given the rudiments of a bacteriological training to enable him to face the biological problems that crop up in the factories.—I am, Sir, etc., David Ellis

Sir,—I have seen in your issue of October 5 a review of the book, *Practical Bacteriology for Medical Students*, by Dr. Ellis. While I am fully in agreement with most of the criticisms of your reviewer, there is one point on which I beg to differ. I have found in actual practice that it is best not to counter-stain in carrying out Gram's method of staining. If the diaphragm is well cut down and a good light is employed, there is no difficulty whatever in seeing Gram negative organisms, and the distinction between Gram negative and Gram positive is very much more marked than is the case if a counter-stain is used. Moreover, the latter tends to obscure the slight differences in degree of staining which certain organisms exhibit. It seems to me probable that Prof. Ellis has reached the same conclusion, and that is why he does not advocate counter-staining.—I am, Sir, etc., R. F. Hunwicke

THE CHEMICAL ENGINEER

Sir,—I am not sure that the academic ventilation of definitions or a discussion on the functions of this reputedly weird species is likely to be of value outside the chemical engineering community, because in my experience the only people who really have an adequate notion of the functions, training and uses of a so-called "Chemical Engineer" are those who employ a competent one or else the trained chemical engineer himself. One of your correspondents is unconvincing because he endeavours to judge chemical engineers by the books they read, but Mr. Gray is both entertaining and suggestive.

Do your correspondents really think that it would be desirable to include in a book on chemical engineering or its principles, chemistry, which can be better culled from standard text-books written by real chemists? My experience of chemical engineers is that when properly trained they refuse to pad their books or their brains with unessentials, and it is ridiculous to think that because chemical engineering rests largely on engineering, physics and common-sense, that in the works or in practice a chemical engineer is not in daily contact with chemistry and chemical processes for which a substantial leaven of chemistry in his training is obviously essential. To call such a man a physical engineer would be a terrible indictment, and although his function is sometimes that of a doctor versus a patient, the administration of the physic and its proper compounding usually requires knowledge both of chemistry and business. The latter ingredient is, unfortunately, often overlooked. How would Mr. Greenfield, as a logical sequence to his letter, define a "Physical Chemist," and what would he think of a book on physical chemistry which says nothing about the principles of chemical engineering, which he seems to consider as a branch of "Physics"?

Why not simply accept the fact that a hybrid species has been gradually evolved during the last decade, which the general public has, rightly or wrongly, become accustomed to call a "Chemical Engineer," and leave it at that? The hybrid which is suitable for a by-product or acid plant would hardly be suitable for the control of complicated organic processes, unless his training has been wide enough, and, for instance, in America there has been a tendency to subdivide the hybrids into organic and inorganic chemical engineers. The definitions, if any, and educational work are, since the

Institution of Chemical Engineers has come into active being, in safe hands.

In conclusion, I think Mr. Gray was not quite fair to Liddell's "Handbook on Chemical Engineering," in that he made little reference to volume 2, which, in my opinion, contains just as much chemistry as is desirable, rightly leaving the reader to consult known text-books for the rest, instead of endeavouring to publish a kind of encyclopædia, which, if completely assimilated by our budding hybrid, would produce a "dud."—I am, Sir, etc.,

C. J. Goodwin,

708, Idol Lane, London, E.C. 3

THE CHEMIST AND BUSINESS TRAINING

Sir,—In your editorial in the *Journal* of October 12 reference was made to a matter of considerable importance at the present time, viz., the relationship between training in chemistry and business training.

If the number of men who combine a keen business sense with adequate scientific knowledge and judgment is comparatively few, one is compelled to assert that the cause is not to be traced to hereditary inability of the "brains" of this nation to unite the two faculties in one man.

Those examples of such a desired "finished product" whose names are familiar to many of us must inspire many young men in our colleges with a real wish to develop towards a similar career.

What, then, is the obstacle to the fulfilment of this laudable desire? The sons of wealthy business men who are fortunate enough to start with a training in chemistry and to proceed (the necessary opening for them in industry having been provided in advance) to a responsible post with scope for their ideas and special facilities for gaining business experience, need not concern us here.

Our problem is connected with the young chemists who are graduating in large numbers from the Universities and for whom, apparently, very few posts are available.

Whilst it may be true that "if suitable men are chosen in good time the desired result will be obtained," what machinery is proposed for finding the right type of man and for grafting upon him the business training which, combined with his particular scientific bent, will tend towards productive results?

Those most important "twenty years in laboratory and lecture room" have laid what we believe to be the sure foundation; it is immediately upon their completion that the necessity arises for the inculcation of business responsibility together with opportunities for advancement, provided that the candidate's rate of progress corresponds with the first estimate of his ability.

Two urgent requirements would seem to present themselves. The first is that undergraduates in our schools of chemistry should be made to realise that not every person with a degree is destined for a purely chemical post, *e.g.*, in research or applied chemistry. This means also that the "control" and "costs" side of chemical operations must never be lost sight of in our teaching, both theoretical and practical.

The second is that our "captains of industry," works directors, and managers of all departments should be alive to the possibilities of introducing young men with scientific training into every branch of the businesses which they control, so that chemistry may be applied as much outside the laboratory as inside.

In conclusion, whilst one is aware that amongst the great industrial concerns and also in the Universities and colleges there are many gentlemen of high standing who have had the conviction and foresight to face these problems and to point the way to a solution, the need of the moment is that experiments on similar lines be tried as widely as possible.—I am, Sir, etc.,

William Doran

Dept. of Organic Chemistry,
Liverpool University
Oct. 17, 1923

THE CHEMIST IN INDUSTRY

Sir,—Whilst fully accepting the editorial decree that my recent article, entitled, "The Chemist and Industry," should be regarded as raising the issue of the "Chemical Engineer," I cannot but express regret that the original title "chemist" was not retained. However, in replying to the correspondence on the subject, I may say that the criticisms put forward have been very fair and not nearly so drastic as one might have expected. Mr. G. J. Greenfield, whilst he seems to be tired of the subject, cannot refuse to discuss it. That, Mr. Editor, proves the perennial fascination of the question and explains a good deal. I cannot agree that the subject can ever become stale while there is such a great discrepancy between the ideal treatment of chemists and the present state of affairs. Further, age in a maxim is like age in good wine—it indicates quality and potency. With regard to Mr. Greenfield's point about the neglect of physics, nobody will disagree with him, but surely he is a physical extremist?

In reply to Mr. H. A. Wilson's courteous letter, I have re-read with care the original article and can find no condemnation of the "professional chemical engineer" as such. The object of my criticism was always the *soi disant* chemical engineer, and one cannot but wish well to all such bodies as the Institution of Chemical Engineers and their efforts to set a high standard of initial attainment before admission.

By the phrase "that the directing intelligence of chemical concerns should be of a chemical nature," I certainly do not mean that the managing director of a chemical firm should necessarily have a diploma as a chemist. The purposely general nature of the phrase was intended to imply something better than that—namely, that the technical strategy, as well as the actual works tactics, should be decided upon after due weight (and recognition) has been given to the counsels of the chemist. That means that chemists must be represented on the board of directors. It is inclusion that I plead for, not exclusion. Mr. Wilson's ideal of a manager or managing director, though the point is not raised by me, seems to be a very high one, and I am doubtful of the frequency with which such very able men can be found. I would be satisfied with an honourable business man, preferably a University man, who, as an organiser, gives "due weight and recognition to all his staff" and persuades them to sink self in the general good. That is the essence of organisation.

Although, from his letter, Prof. Partington would seem to have read only the correspondence and not the causative article, I must express my obligation to him for so carefully dotting my "i's" and crossing my "t's" even to the extent of supplying the original reference. His list of subjects will inevitably be studied by any future chemical engineer who takes the course recommended in my article. To his plea for the co-operation of the older men in helping the young novice to find his feet I would offer my hearty support: it is difficult for the young graduate to work in an atmosphere of sullen resentment from older men, and a little charity would help a great deal.

It will, I think, do no harm if I make the chief points in the article to be:—(1) I am not ashamed to plead for special treatment for the highly specialised product who nowadays is turned out from the Universities. He ought not to be subjected to treatment other than that due to a gentleman. Britain needs chemists. (2) Mind must be given its due place in the chemical industry as apart from "smartness." (3) True economy and speed would indicate that adult education applied to men already in the profession would save much time and produce an atmosphere of good fellowship which we shall need very much in the critical decade which lies before us. (4) There is no real difference between pure chemistry and so-called applied chemistry. The only difference is in point of time. Fuel technology in this country is a direct outcome of the pioneer teaching of Dixon, as any sensible man is proud to acknowledge. The technology of gas heating and carbonisation has been stimulated and clarified by the researches of Smithells, Cobb and Wheeler, whilst the colloidal and cognate industries must find material of enormous value in the address to Section B given by its President at the last British Association meeting. Let us give credit where credit is due. Even "surface combustion" is a model of what extra aeration can do with a gas flame. (5) Lastly, Science should be taught as one of the "Humanities."—I am, Sir, etc., H. H. GRAY

Chemical Dept., Technical College,
Huddersfield
October 22, 1923

PERSONALIA

The Council of the Institution of Civil Engineers has made the following awards in respect of selected engineering papers published without discussion during the session 1922-23:—A Watt Medal to Mr. T. E. Houghton, M.Eng., Assoc.M.Inst.C.E. (Liverpool), and Telford Premiums to Mr. J. W. Meares, C.I.E., M.Inst. C.E. (Guildford), Mr. J. W. Spiller, M.Inst.C.E. (Maidenhead), and Messrs. G. S. Coleman, D.Sc., Assoc.M.Inst.C.E. (Manchester), and Dempster Smith, M.B.E., M.Sc., Tech. (Manchester); and in respect of papers read before meetings of students of the Institution in London and the provinces during the same period:—Miller Prizes to Mr. E. L. Everatt, Stud.Inst.C.E (Newcastle), Mr. J. G. Kimber, Stud.Inst.C.E. (London), Mr. A. H. Naylor, M.Sc., Stud. Inst.C.E. (London), Mr. E. Sykes (Birmingham), and Mr. F. J. Symonds, Stud.Inst.C.E. (London).

To mark the completion of forty years' service with the firm of Bayer & Co., Prof. C. Duisberg is to be presented with a volume containing his collected works and discourses.

* * *

The death is announced from France of Prof. Minguin, professor of chemistry in the Faculty of Sciences at Nancy, well known for his attempts to synthesise the diamond. Prof. Minguin was one of those to whom the Jecker prize had been awarded.

From Germany the death is announced of Prof. H. Geitel, hon. professor in the Technical Hochschule at Brunswick, and an active worker in the field of radium investigation.

The death is reported of Dr. H. E. Richards, of Bloomfield, N.J., president of the Martin Dennis Co., Newark, N.J., a manufacturer of chemicals. Also of Prof. A. J. F. da Sibra, professor in the University of Oporto, and for many years director of the Municipal Laboratory.

From Germany the deaths are announced of: Dr. B. Jaffé, founder of the Vereinigte Chemische Werke A.-G., Charlottenburg; Dr. H. Byk, founder of the Chemische Werke vorm. Dr. H. Byk, Charlottenburg; K. Heidenreich, well known in the gas world.

NEWS AND NOTES

AUSTRALIA

Establishment of a Chair of Metallurgy

In order to establish a chair of metallurgy at the Melbourne University, the Australian Mines and Metals Association has guaranteed the sum of £400 per annum from its members, which, together with the amount of £600 at present paid to a lecturer and assistant, will cover the costs of the chair.

UNITED STATES

Silver Anniversary of Chemists' Club in New York

Arrangements have been made to celebrate, on October 25, the silver anniversary of the founding of the Chemists' Club in New York. The festivities are to be in the nature of a home coming, and special efforts are being made to bring together on that day all those through whose efforts the club has achieved its present degree of success.

CANADA

Nickel

Approximately 1000 tons of ore is being treated daily at the British-American smelters at present. The second furnace of the British-American Nickel Co. has been blown in, and is rapidly reaching maximum production. The erection of a third furnace is in hand, but will not be in commission for another 6 months. With both furnaces operating at capacity, it is hoped that the monthly amount of ore treated will be close on 50,000 t.

FRANCE

Notes from Paris

The metallurgical market is in no hurry to interpret the recent political events. French industry is aware of the disadvantages that could arise from a restriction of the metallurgical and coal enterprises of the Ruhr. In general, prices of metallurgical products are expected to fall steadily but slowly.

Three decrees, issued on September 26, regulate the sale prices of nitrated cotton.

The production of the "Domanial" Mines of the Saar reached 1,096,959 metric tons in July, as against 1,025,716 t. in June. Altogether these mines found employment for 76,039 workers and employees.

JAPAN

The Mineral Industry

The aggregate value of the Japanese mineral output in 1922 reached 346,813,540 yen, against 332,620,331 yen in the previous year. The 1922 output was as follows (the figures for 1921 being shown in parentheses) :—Lead, kin 5,398,657 (5,229,938); bitumen, kin 4350 (1233); quicksilver, kin 2009 (9916); zinc, kin 20,618,336 (17,289,352); chrome iron ore, kwan, 1,001,921 (898,186); manganese ore, kwan, 1,183,946 (1,034,836); arsenic acid, kin 3,406,091 (2,325,745); arsenic ore, kwan 612,083 (401,657); phosphates, metric tons 12,330 (32,001); graphite, kin 1,742,700 (1,449,538); crude petroleum, koku 1,799,096 (1,961,068); natural gas, 1000 cu. ft., 1,144.416 (1,091,975); pitch, kwan 74,646 (1,850,370); sulphur, metric tons 34,642 (3659); sulphur ore, metric t. 42,089 (30,631). A summary report issued by the Japanese Bureau of Mines states that the output of zinc, bitumen, lead, arsenic, pitch, petroleum, graphite and sulphur exceeded previous records.

GENERAL

The Journal of Scientific Instruments

It is announced that arrangements have now been made for the regular monthly publication of the *Journal of Scientific Instruments*, and the first number appeared on October 15. The Journal contains 32 pages of reading matter and is somewhat similar to the preliminary number, copies of which have already been sent out. The annual subscription to the Journal, which is produced by the Institute of Physics, with the co-operation of the National Physical Laboratory, is 30s., including postage (24s. to corporate members of the Institute of Physics). Single copies are sold at 2s. 6d. each, post free 2s. 9d. Copies can be obtained from the Secretary, Institute of Physics, 10, Essex Street, London, W.C. 2.

New Russian Industrial Chemical Journal

A new journal is being published in Berlin in Russian under the editorship of Prof. Ipatieff, for Russia, and Prof. Grossmann for Germany. The object of the journal is to keep Russian technical chemists in touch with developments in chemical industry in Germany and other countries.

British Phosphate Commission's Report, 1922-23

According to the above report, favourable conditions were experienced both at Nauru and Ocean Island during the period reviewed, and operations were conducted in a satisfactory manner. The *Nauru Chief*, a steamer of 4000 tons dead weight, was acquired, and the tonnage of phosphate cargo shipped amounted to 361,205 t., compared with 364,251 t. for the previous year. Australia received 47·20 per cent. of the shipments. New Zealand 10·64, the United Kingdom 4·45, and other countries 37·71. All demands for the United Kingdom, Australia, and New Zealand were met at satisfactory prices, and the surplus output was disposed of to other countries at market rates. The trading account for the year showed that the receipts from sales of phosphates and sundry credits, less freight and insurance, amounted to £823,044. The f.o.b. cost of phosphate, including interest on capital, contribution to a sinking fund for the redemption of capital, and other charges specified in the agreement, was £732,406. The credit balance for the year was therefore £90,637.

REVIEW

The Determination of Hydrogen Ions. *By* W. Mansfield Clark. *Second edition reprinted. Pp.* 480. *References* 2000. *Baltimore, U.S.A.: Williams and Wilkins,* 1923. *Price* $5.50.

When the first edition of this book appeared in 1920, the reviewer welcomed it as an authoritative exposition of an important subject, the applications of which are increasing rapidly, and which is of fundamental importance, particularly to the biological sciences. In the short time that has elapsed since then, a reprint of the first edition and a second edition in 1922 have become necessary. The latter having already become exhausted has now been reprinted. These facts are evidence of the widespread recognition among chemists of the importance of hydrogen-ion concentration, and of the growing interest that is taken at the present time in its determination. The reviewer was able to commend the first edition for clearness, trustworthiness, comprehensiveness and interesting style. These features have been well maintained in the edition now before us. The book has been brought up to date by the inclusion of the work done in the interval since its first publication. Of the new items which have appeared of particular interest, mention may be made of the description of the quinhydrone electrode, the account of Goode's application of the electron-tube to the control of hydrion concentration and the detailed discussion of Gillespie's and of Michaelis' and Gyemant's work on colour matching of indicators. These, however, by no means exhaust the new work incorporated. To the technical applications summarised in the first edition have been added descriptions of those of a more purely scientific character. The number of bibliographical references has been increased from about 1100 to 2000. The author has evidently been at pains to widen the appeal of the book, so as to make it suitable for as large a number of readers as possible, and the experience gained of difficulties encountered by students and others has doubtless been utilised in the preparation of the present edition. Many chapters have been rewritten, some have been divided into two, and the discussion is fuller throughout. As a result, the number of pages has grown from 312 to 480, without, however, making the first edition obsolete, as might be at first supposed. The price has remained the same.

The book can be confidently recommended not only to those seeking information on hydrion-determination for purposes of scientific research or technical application, but also to the wider class who may wish to become acquainted with the general principles governing the subject from the purely scientific aspect.

Henry J. S. Sand

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Oct.* 18)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia	Steel sheets	413
Belgium ..	Paper	420
British India ..	Steel rails, sodium nitrate, iron posts (tender) ..	*
Egypt ..	Paper (tender)	11642/F.E./M.P.
Finland ..	Iron, steel, brass and copper pipes	423
Netherlands	Aluminium, enamel-ware, chinaware, crystal glassware	427
Norway ..	Untarred roofing paper ..	429
South Africa ..	Disinfectant fluid (tender)	12337/E.D./C.C./2
,, ..	Red oxide paint (tender)	12338/E.D./C.C./2
,, ..	Chemical coagulants (tender)	12342/E.D./C.C./2
Sweden ..	Rails, angle-iron ..	433

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, S.E.1.

TARIFF CUSTOMS EXCISE

British Guiana.—An increase has been made in the export duty on refined petroleum.

Italy.—Under the "temporary importation" system, zinc scrap, iron and steel, brass, aluminium, and metallic materials may be imported duty-free.

Lithuania.—The export duty on hides has been retained.

Southern Rhodesia.—Prohibition has been declared of the importation, exportation, production or manufacture of any habit-forming drug, except under permit.

Tunis.—Imports of anthraquinone are duty-free.

NEW SOURCE OF PETROLEUM IN RUSSIA

A new petroleum well at Maikop, in Kuban, Northern Caucasus, has recently been producing 3000 t. daily of a light petroleum oil, rich in benzine.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No material changes have taken place in the heavy chemical market either in demand or prices. Considering the general state of trade chemical products are in satisfactory request, although of course very considerably below what would be expected in more normal times. The home trade is steady but quiet, and the main features in export lines continue to be the "heavier" classes of alkalis.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 6d. per carboy makers' works.
Acid Nitric 80° Tw.	£22 per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb. d/d.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Business in this section is generally on the dull side.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb. Reduced 1s. per lb. following drop in metal.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Regular demand and short supply.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade. Market quiet owing to slack demand for non-ferrous metals.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d.—6s. 4d. per gall. 60% O.P. Steady market.
Solvent	6s. per gall. 40% O.P. Good demand.
Wood Tar	£5—£6 10s. per ton, according to grade. Slightly weaker.
Brown Sugar of Lead	£41—£42 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Fair inquiry. Good business for prompt delivery.
Crude 60's	3s. 6d.—3s. 7d. per gall. Good demand for spot delivery. Supplies limited.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Steady demand.

Acid Cresylic	
Pale 95%	1s. 7d.—2s. 4d. per gall.
Dark	1s. 7d.—2s. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—10d. per gall.
Unstrained	8½d. per gall.
Benzole—	Fair enquiry.
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 6d.—1s. 7d. per gall. Little business passing.
Pure	1s. 9d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8¼d.—9¼d. per gall. according to grade and district. Demand still good.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 1½d.—1s. 3d. per gall. Prospects brighter. Market steady.
Solvent 90/190	1s. 3d.—1s. 4½d. per gall. Market flat.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. More inquiry. Difficult to meet demand.
Whizzed or hot pressed	£9 10s.—£11 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	130s.—140s. per ton, according to district and time of delivery. Several inquiries. Market firm and price tending to advance.
Pyridine—90/140	21s.—22s. 6d. per gall. Market very strong.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Dyestuffs business has been steady during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Quieter.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Better demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S, Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£85 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	4s. 10d. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Market more active and makers well employed. Prices gradually rising with steady tone in view of lack of foreign competition.

Acid, Acetic 80% B.P.	£47 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d.—3s. 6d. per lb. Good demand. Firm market. Shortage not improbable.
Acid, Benzoic	2s. 6d. per lb. Higher prices would be paid for good B.P. quality, which is unobtainable.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 5d. per lb., less 5%. for ton lots. Poor demand.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb.
Acid, Salicylic	2s. 4d.—2s. 6d. per lb. for 5 cwt. lots. Firm market. Prices advancing.
Acid, Tannic	3s. per lb. for B.P. quality.
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Demand poor. Second-hand parcels reported at less than 1s. Germany offering at 1s. 0½d. per lb. Raw material dearer.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 7d.—1s. 10d. per lb. for English manufacture. Large orders in hand.

Amidopyrin	13s. 6d. per lb. for spot stocks with little coming forward.
Ammon. Benzoate ..	3s.—3s 6d. per lb., according to quantity.
Ammon. Carbonato B.P.	£32 15s per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make. In better demand.
Barbitone	17s. per lb. Neglected.
Benzonaphthol	4s. 9d. per lb.
Bismuth Salts	A steady market. Carbonate 13s., Nitrate 6s. 11d., Salicylate 10s. 5d., Subgallate 9s. 6d., Citrate 11s. 7d., Oxide 14s. 5d., Subchloride 12s. 8d., Subnitrate 11s.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	6½d. per lb. Show slight improvement. Ample stocks exist.
Ammonium	7d. ,, ,,
Sodium	7½d. ,, ,,
Calcium Lactate ..	2s. 6d. per lb.
Chloral Hydrate ..	4s. per lb. In active demand. English makers are oversold.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate ..	9s. per lb. Little demand.
Guaiacol Carbonate ..	10s.—11s. 6d. per lb. for spot. Supplies short.
Hexamine	4s. per lb. Very steady.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate ..	Reduced by 2d. per lb. 2s. 3d. per lb. for cwt. lots. 2s. 4d. for 28 lb. lots.
Magnesium Carbonate—	
Light Commercial ..	£36 per ton net.
Magnesium Oxide—	
Light Commercial ..	£80 per ton, less 2½%.
Heavy Commercial ..	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 72s. 6d. per lb.
Methyl Salicylato ..	2s. 6d.—2s. 10d. per lb. In strong demand.
Methyl Sulphonal ..	14s. 6d. per lb. No demand.
Morphine and Salts ..	Prices again advanced owing to dearness of opium. Alkaloid: Cryst. 14s. 8d., Precip. 14s. 5d., Acetate 11s. 6d., Hydrochlor. 11s. 6d., Sulphate 11s. 6d., Tartrate 14s. 5d. per oz.
Paraformaldehyde ..	3s. 9d. per lb. More active. Higher rates for forward delivery.
Paraldehyde	1s. 5d.—1s. 5½d. per lb. Some holders asking 1s. 6d.
Phenacetin	6s. 3d. per lb. Demand active.
Phenazone	7s. 9d. per lb. Firm. Price advancing.
Phenolphthalein ..	7s. per lb. Scarce. Very firm.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Fair business passing.
Potass. Ferricyanide ..	3s.—3s. 6d. per lb.
Potass. Iodide	15s. 8d.—16s. 2d. per lb. Good demand.
Potass. Permanganate ..	10d. per lb. for B.P. crystal.
Quinine Sulphate ..	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb. Higher prices expected.
Salol	4s.—4s. 6d. per lb. Very scarce.
Sod. Benzoate	2s. 6d. per lb. Spot supplies not plentiful.
Sod. Citrate, B.P.C. 1923	Reduced to 2s. per lb. for cwt. lots. Makers kept active.
Sod. Hyposulphite—	
Photographic ..	£15—£17 per ton, according to quantity, d/d. consignee'a station.
Sod. Potass. Tartrate (Rochelle Salt) ..	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 8d. per lb., and Crystal at 2s. 9d. per lb. Firm and active.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.	
Aubepine	14s. ,, ,,	
Amyl Acetate	3s. ,, ,,	
Amyl Butyrate	7s. 3d. ,, ,,	
Amyl Salicylate ..	3s. 6d. ,, ,,	
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,	Higher prices anticipated
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,, ,,	
Benzyl Alcohol free from Chlorine	3s. ,, ,,	
Benzaldehyde free from Chlorine	3s. ,, ,,	
Benzyl Benzoate ..	3s. 9d. ,, ,,	
Cinnamic Aldehyde Natural	20s. ,, ,,	
Coumarin	20s. ,, ,,	
Citronellol	20s. ,, ,,	
Citral	9s. 6d. ,, ,,	
Ethyl Cinnamate ..	10s. ,, ,,	
Ethyl Phthalate ..	3s. 9d. ,, ,,	
Eugenol	10s. ,, ,,	
Geraniol (Palmarosa) ..	37s. 6d. ,, ,,	
Geraniol	6s. 9d. to 13s. 6d. per lb.	
Heliotropine	8s. per lb.	
Iso Eugenol	15s. 9d. per lb.	
Linalol ex Bois de Rose ..	18s. 6d. ,, ,,	
Linalyl Acetate	18s. 6d. per lb. Considerably cheaper.	
Methyl Anthranilate ..	8s. 6d. per lb.	
Methyl Benzoate ..	6s. ,, ,,	
Musk Ketone	47s. 6d. ,, ,,	
Musk Xylol	13s. 6d ,, ,,	
Nerolin	4s. ,, ,,	
Phenyl Ethyl Acetate ..	10s. ,, ,,	
Phenyl Ethyl Alcohol ..	16s. ,, ,,	
Rhodinol	47s. 6d. ,, ,,	

Safrol	2s. „ „
Terpineol	3s. „ „
Vanillin	22s. 6d.—23s. per lb. Firm and steady demand. Raw material dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. „ „
Bergamot Oil	13s. „ „ spot.
Bourbon Geranium Oil	37s. „ „
Camphor Oil	80s. „ „
Cananga Oil, Java	9s. 6d „ „
Cinnamon Oil, Leaf	4¾d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 6d. „ „
Ceylon	4s. 2d. per lb. Very little on offer, too many parcels arriving containing spirit. These have been seized by the Customs.
Clove Oil	8s. 6d. per lb.
Eucalyptus Oil 70/75%	2s. 9d. per lb.
Lavender Oil—	
French 38/40% Esters	26s. per lb.
Lemon Oil	2s. 10d. per lb.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil	24s. 6d. per lb.
Peppermint Oil—	
English	70s. per lb. Market very unsteady.
Wayne County	15s. per lb. Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	8s. 9d. per lb. Dearer.

TRADE NOTES

Trade Information

Fine Chemicals.—The latest catalogue issued by The British Drug Houses, Ltd., reveals a further expansion of the range of fine chemicals supplied by this firm for research, analytical and bacteriological work. Amongst the new products listed are nearly 100 new compounds, and the already wide choice of indicators for determining hydrogen-ion concentration—a B.D.H. speciality—is increased by the addition of 5 new ones, viz., benzeneazobenzylaniline, brilliant cresyl blue, bromocresol purple, α-naphtholbenzoin and phenoltetrachlorphthalein. Attention should be drawn to the B.D.H. universal buffer solution (prepared according to the formula devised by Dr. E. B. R. Prideaux) and to the B.D.H. comparator case, which provides in compact form everything necessary for the rapid determination of hydrogen-ion concentrations. Recently we have received testimony to the value of the service which The British Drug Houses is doing in supplying such a wide range of research and other fine chemicals, and we learn that proofs of equal appreciation are coming from abroad.

The Plauson Colloid Mill.—We have received a catalogue issued by Plauson's Mill and Filter Press, Ltd., of 17, Waterloo Place, London, S.W. 1, describing the Plauson system of mixing, disintegration and emulsification. The mechanical element in this system is the Plauson colloid mill, in which the usual friction and pressure between relatively slowly moving elements is replaced by exceptionally high velocity communicated to semi-liquid contents by beaters having a peripheral speed of 3000 metres per minute and passing between stationary anvils. The chemical agents, or "dispersators," used to assist in disintegration and to prevent re-agglomeration, vary with the substance under treatment. These "dispersators" are usually innocuous and cheap materials such as gum, glue, gelatin and soap. The catalogue contains a full description of the colloid mill and of its industrial and scientific applications, and concludes with photomicrographs of various materials showing the results of treatment by the Plauson method.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, NOVEMBER 2, 1923 No. 44

EDITORIAL

"THEY order, said I, this matter better in France." It is a good many years since this was written, and there are yet some matters which they order better in the country of our ally. The first thought which occurred to us on our visit to the Annual Meeting of the Société de Chimie Industrielle was the extraordinary excellence of the social gatherings provided for the entertainment of those who were present. All such chemical gatherings are distinguished by hospitality; we are fond of our colleagues and are glad to meet them, and there is consequently a sincerity about the welcome which lifts such occasions above the usual level. But the recent receptions and banquets in Paris had a distinction to which we cannot attain in England and which we ought to hold before us as an example, a goal to which we should strive. The decorations, the music and the dancing were as refined, as dainty and as artistic as anyone could wish. Nothing short of the best is good enough for the French chemists and the ladies who were present. It was worth going from London to Paris to see how artistic our neighbours are. They took pains to have a high standard in everything, light agreeable music by the best composers, performed by the best artists. The speeches, too, were excellent, and the reason is obvious: the French are proud of their language and take pains to write it and to speak it, not only correctly but even elegantly. Here many of us are too apt to express our thoughts simply and bluntly, caring but little except to make ourselves understood and to end the task. Our language is a noble one, melodious and sonorous; our literature one of the finest and richest the world has ever known. Why should not we, especially our academic leaders, take an equal pride in the expression of our thoughts instead of leaving this almost to chance? Fortunately there are a few both here and on the other side of the Atlantic who take pains over their writing, but how many in both continents are content with a diction and a style which are more appropriate to the warehouse than to the library.

* * *

We think a comparison of the artistic taste of the French and the English will convince us that in another respect we fall short of the high standard to which our neighbours have attained. Many of the French chemical advertisements are things of beauty and joy—if not for ever—at least for a few minutes after the hasty perusal we give to such pictorial demonstrations. Ours rarely attain to any grace or artistic feeling; the feat is not beyond our powers, and we call to mind a picture of a steamer adjoining a dock building which sometimes appears in our pages; when it does it affords us a considerable though transitory pleasure. This is not decisive, the true test is to hand over to some young children a few numbers of our *Journal* and a few of *Chimie et Industrie* with permission to cut out from the advertisements some pictures for a scrapbook. They will not be biassed by any knowledge that the soda which bears the Crescent Brand is probably good enough for many practical purposes, or that the Analytical Reagents "A.R." are guaranteed to be of exceptional purity. We may therefore safely take them as impartial judges of the pictorial qualities of the advertisements, their power of catching the eye and retaining the attention. We have before us a charming booklet giving a number of pictures and some notes about the firm of Messrs. Berk; of course, it is an advertisement, but it will stand the test. No doubt most of us receive an immense number of advertisements of things which we do not want or cannot afford; among the latter are loans negotiated with the utmost secrecy and despatch, motorcars and trips to the Riviera. Some of these advertisements are so well got up that it seems a pity to consign them at once to the waste-paper basket, and they lie about the house until they attain that contempt which is the result of familiarity. Probably they have in this way answered their purpose. But what a sudden and ignominious fate is in store for the advertisements which are dull, dreary or ugly. With the assistance of some very junior members of the chemical profession we are preparing a record of the chemical manufacturers and the goods and wares they advertise, but the right of admission to this record is jealously restricted; it is a case of the survival of the fittest.

* * *

Although the announcement of the award of the Nobel Prizes for medicine for 1922 and 1923, which we record in another column, may seem remotely connected with chemistry, yet it is of distinct interest, as the awards have been made, not only to four physiologists, but to three British subjects. It is true that Professor Hill has been more interested in the physical rather than the chemical side of physiology, but the point can be neglected. There can be no one but will concur with the justice of the award to Dr. Banting, the discoverer of insulin, though, as he does, all will regret the omission of the name of his co-worker, Dr. Best. It is legitimate to feel a sense of pride when we recall the number of British names included in the list of recipients of Nobel Prizes, though it may be doubted if, in proportion to population, any other country has so distinguished a record as Holland in this respect. The Nobel Prizes for physical science and chemistry are awarded by the Swedish Academy of Sciences, and those for physiology and medicine by the Caroline Institution of Stockholm, all the awards being made without distinction of nationality. Amongst the names of British subjects who have received Nobel Prizes for their distinguished work in physical and chemical science are those of Rayleigh, Ramsay (both in 1904), Thomson (1906), Rutherford (1908), and the Braggs (1915), but until the present year, Sir Ronald Ross, who discovered the method of transmission of malaria, was the only Englishman who had received a Nobel Prize for physiology. The times have changed since Burton wrote that "They can make fire it shall not burn, fetch back thieves, salve gouts, epilepsies, biting of mad dogs, make men young again, as the Spanish Marquess is said to have done and some which jugglers in China maintain still that they can do by their extraordinary skill in Physick and some of our modern Chemists by their strange limbecks, by their spells, Philosopher's stones, and charms," but the achievements of the Nobel prizemen, and, indeed, of modern science in general, will long make a wonderful tale. It is recorded that Nobel was a chemist and engineer. Was he a chemical engineer?

CO-ORDINATION AND ACIDITY

By Prof. T. M. LOWRY, F.R.S.

In my previous article (*Chem. & Ind.*, Oct. 19, p. 1004), I found myself in agreement with Dr. Main Smith in admitting that Werner's theory of co-ordination had been very slow in receiving the recognition it deserves, although I differed fundamentally in my diagnosis of the reasons both for the tardiness of this recognition and for the widespread popularity which this theory is now gaining. These opposing influences can be seen in the subject of the present article, in which an attempt is made to find a modern interpretation of an aspect of Werner's theory, which has been universally neglected, since (so far as my experience goes) it has not been adopted by any subsequent author, either in a text-book, or even in original papers dealing with the very same topic, namely, the origin of acidity and basicity.

1. *The Uniqueness of Hydrogen.* In an earlier article (*Chem. & Ind.*, p. 43) the view was advanced that the separation of a proton is the unique cause of acidity. On the other hand, basicity, as representing merely the power to capture a proton, was regarded as a more general property, which can in fact be found (i) in molecules, such as ammonia, which are capable of passing into kations by combination with a proton, (ii) in negatively charged anions, such as the $\overset{-}{O}H$ of the alkalis, which are reconverted into neutral molecules by a similar process.

The uniqueness of hydrogen has been emphasised still further by recent work on atomic structure. Thus, in the Faraday Society's discussion on "The Electronic Theory of Valency," Mr. R. H. Fowler stated that there was no difficulty in picturing *two* mechanisms to represent the electrovalence and covalence of chlorine, *e.g.*, in $\overset{+}{N}a\overset{-}{C}l$ and Cl—Cl; but in the case of the hydrogen ion, where the positively charged nucleus consists of a proton with no surrounding shell of electrons, it appeared to be impossible to devise a system in which the proton, when attracted by an ion of opposite sign, could be kept from falling inside the orbits of the outer electrons of that ion. In other words, in the case of hydrogen, a single type of valency appears to take the place of the two types which are met with in other elements. This recalls the old controversy as to whether univalent hydrogen should be regarded as a lower homologue of the univalent alkali metals, or of the univalent halogens. Hydrogen appears to be unique in that it shows analogies with *both* families of elements, with the ion-forming alkali-metals as well as with the bond-forming halogens. One may, therefore, use a certain amount of latitude in representing the link, *e.g.*, between hydrogen and chlorine, either by a bond, or by the $+-$ sign of an electrovalency, since in the unique case of hydrogen the two symbols may perhaps represent the same thing.

Fowler's conclusion, that a proton always tends to fall within the outer orbits of another atom until repelled by the nucleus, is also in intimate agreement with the familiar fact, to which attention was likewise directed in the earlier article, that "strong acidity is apparently developed only in mixtures and never in pure compounds." Thus hydrogen chloride only becomes an acid after being mixed with water. This was explained, in strict accord with Fowler's conclusions, by "the extreme reluctance of a hydrogen nucleus to lead an isolated existence, although it is quite willing to attach itself to any octet that is not too unfriendly, or too fully occupied by other atoms to leave room for an additional nucleus." The view that the ionisation of an acid is not a direct dissociation, *e.g.*,

$$HCl \rightleftarrows \overset{+}{H}+\overset{-}{Cl}$$

but a process of double decomposition, in which a pair of molecules gives rise to a pair of ions, *e.g.*,

$$HCl+H_2O \rightleftarrows \overset{+}{O}H_3+\overset{-}{Cl}$$

appears therefore to have a theoretical basis in the new conceptions of molecular structure which are gradually being developed from Bohr's theory of atomic structure.

2. *Co-ordination as a Factor in Promoting Acidity.* The influence of water in promoting the development of acidity is, however, by no means limited to the passive role of an "acceptor of hydrogen ions," since the theory of co-ordination enables us to assign to it an active part in the expulsion of a proton, which is after all the fundamental fact in acidification. In the somewhat analogous case of the ionisation of the chlorides, Werner pointed out that the addition of molecules of ammonia causes a progressive expulsion of chlorine ions from the co-ordination-complex. Thus, whilst the triammine

$$[CoCl_3{\cdot}3NH_3]$$

is a non-electrolyte, of which none of the chlorine can be precipitated by silver nitrate, the tetrammine, pentammine and hexammine, contain respectively one, two and three ionisable atoms of chlorine, as represented in the formulæ

$$[CoCl_2{\cdot}4NH_3]Cl \quad [CoCl{\cdot}5NH_3]Cl_2 \quad \text{and} \quad [Co{\cdot}6NH_3]Cl_3.$$

In the case of an acid, one might picture the hydrogen ions as being expelled by the addition of molecules of water to a co-ordination complex, just as the chlorine ions of cobaltic chloride are expelled by ammonia. This is, indeed, Werner's "Theory of Acids," which he sets up in contrast to the current definition of acids as "compounds of hydrogen which, on solution in water, dissociate, giving hydrogen ions."

The four definitions, which Werner uses to "describe the conception of an acid," owe their complexity to the fact that he finds it necessary to picture every acid as derived from an "anhydro-acid," *e.g.*, HCl or SO_3, which is only converted into a true acid on the addition of water. This has the great disadvantage of limiting the field of vision to water and aqueous solutions; whereas, when acidity is defined as "ability to give up a proton," one can picture precisely the same phenomenon as occurring in other solvents.

3. *Hydration of Multipolar Ions.* Werner's theory of acidity can be expressed in a more precise form, if an attempt is made, with the help of the electronic theory, to localise the electric charges on the various atoms. Thus. Werner represents the conversion of platinic hydroxide into an acid by the addition of two molecules of water by the equation :—

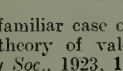
$$(HO)_4Pt+2H_2O=(HO)_4Pt(\overset{-}{O}H)_2+2\overset{+}{H}$$

In this equation four of the hydroxyl-groups are shown as neutral and two as carrying negative charges. Thus unequal treatment of the six hydroxyl-groups can scarcely be maintained, in view of the considerations of symmetry on which the theory of co-ordination is mainly based. It is, moreover, not satisfactory to represent the two negative charges as occupying an indeterminate position in the bivalent ion, as in the symbol $[Pt{\cdot}6OH]^{--}$. Sidgwick's theory of co-ordination (this vol., p. 412) allows us, however, to locate both negative charges on the platinum, as in the formula,

$$\overset{--}{Pt}(OH)_6,$$

the six hydroxyls being held to the platinum by covalent bonds, just like the hydroxyl in alcohol.

In the more familiar case of sulphuric acid, the electronic theory of valency enables us (*Trans. Faraday Soc.*, 1923, **18**, 289) to locate the electric charges on the sulphate ion as follows :—

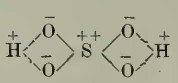


This method of formulation makes it particularly easy to visualise the competition between molecules of water and free protons for a place in the nucleus, which forms the more picturesque version of Werner's theory of activity.* Thus, if we assume (following *Hantzsch.*, *Ber.*, 1917, **50**, 1422) that the proton tends to associate itself with *two* of the negative poles, the undissociated molecule of sulphuric acid may be formulated as in I. But these poles could also be bridged by molecules of water as in II, where the dotted lines indicate contiguous electrostatic charges which may perhaps be replaced by covalent bonds.

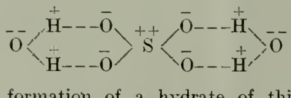
---

* Werner himself lays most stress on the ability of an anhydroacid to annex hydroxyl-groups from molecules of water, thereby releasing free hydrogen ions. The alternative view of a competition between water and protons is expressed in the statement of Morgan and Smith (*T.*, 1922, **121**, 1958) that in certain series of co-ordination-compounds "replacement of water of hydration by positive hydrogen takes place with acids of varying basicity and widely different strengths."

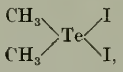
I



II



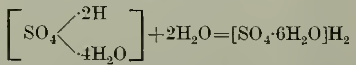
The formation of a hydrate of this type would be favoured by the greater stability of six-atom, as compared with four-atom, rings. It is, however, not easy to determine with certainty how many of these bridge-positions there are to be competed for. Thus, if the four oxygen atoms were arranged in one plane, like the three oxygens of CO_3 in calcite, or of NO_3 in the isomorphous crystals of sodium nitrate, giving rise to the same rectangular configuration as in



there would be only four of these positions. If, however, the four oxygens in the sulphate ion form a tetrahedron, like the four radicals in the sulphonium salts, or the four oxygens in silver molybdate,

$$Ag_2[MoO_4],$$

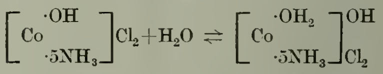
one might expect to find six bridge-positions, as in the tetrahedral basic beryllium acetate investigated by Morgan and Bragg (*Nature*, 1923, **112**,). If the latter hypothesis were correct, the final stage in the ionisation of sulphuric acid in aqueous solution might be represented by an equation of the type



$$\left[SO_4\begin{matrix}\cdot 2H\\ \cdot 4H_2O\end{matrix}\right]+2H_2O=[SO_4\cdot 6H_2O]H_2$$

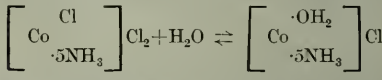
At the present stage, however, it is not necessary to discuss the exact formulæ of these hydrated anions, since the object of this article is simply to direct attention to the analogy between the progressive ionisation of cobaltic chloride as chlorine is expelled by ammonia, and the ionisation of an acid as a result of the expulsion of protons by molecules of water. It is, however, of interest to note that an explanation is thereby afforded of the hygroscopic character of so many of the strongest acids, and also that the hydration of the anion appears to be quite as important as that of the kation.

4. *Werner's Theory of Bases.* Werner's theory of bases had a more direct experimental foundation than his theory of acids, since much of the evidence in favour of the latter view has been obtained only since his death, as in the work of Morgan and Smith already cited. In the case of the bases he was able to quote, as evidence in favour of his views, the actual behaviour of a complex base which presents many points of similarity to the co-ordinated chlorides cited at the beginning of this article, i.e., hydroxo-pentammino-cobaltic chloride. This similarity was shown by writing the compound in two forms, thus :—



$$\left[Co\begin{matrix}\cdot OH\\ \cdot 5NH_3\end{matrix}\right]Cl_2+H_2O \rightleftarrows \left[Co\begin{matrix}\cdot OH_2\\ \cdot 5NH_3\end{matrix}\right]\begin{matrix}OH\\ Cl_2\end{matrix}$$

It will be seen that in the above scheme Werner postulates that the hydroxyl is expelled from the co-ordination sphere by a molecule of water, just as a third chlorine ion can be expelled from pentamminocobaltic trichloride by an additional molecule of ammonia or of water :—



$$\left[Co\begin{matrix}Cl\\ \cdot 5NH_3\end{matrix}\right]Cl_2+H_2O \rightleftarrows \left[Co\begin{matrix}\cdot OH_2\\ \cdot 5NH_3\end{matrix}\right]Cl_3$$

Whereas, however, the two chlorides could both be isolated, the two formulæ for the base were assumed to correspond with the non-ionised and the ionised constituents of an aqueous solution, from which only the former could be separated by crystallisation.

On the basis of his interpretation of the ionisation of these complex cobaltic salts, Werner defines bases in general as "*addition compounds with water which form hydroxyl ions in aqueous solutions.*" The substances from which addition-compounds of this kind are formed by the addition of water were described as *anhydrobases.*

5. *Lewis' Theory of Acids and Bases.* Prof. G. N. Lewis will, I hope, forgive me if at this stage I venture to direct attention to a further extension of Werner's theory of acidity which is contained in a forthcoming volume, of which he has very kindly allowed me to see the proofs. In order to get away from the limitation to aqueous electrolytes, which is characteristic of Werner's definitions, Lewis suggests that :—

> "An acid is a substance which gives off the cation or combines with the anion of the solvent ; a base is a substance which gives off the anion or combines with the cation of the solvent."

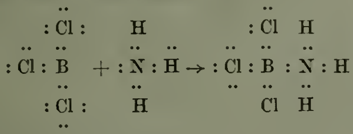
Potassamide, KNH_2, is therefore a base in liquid ammonia, whilst KCl would become a base if liquid hydrogen chloride were used as the solvent.

The idea that acidity and basicity are not inherent properties, but depend on the selection of a solvent, can, however, be got rid of by taking hold of the fact that in ordinary neutralisation, a proton makes use of a "lone pair" of electrons (*e.g.*, an unoccupied pair of electrons of the nitrogen-octet of NH_3 or of the oxygen-octet of $\bar{O}H$) to complete its own stable group, which in this case is not octet but a duplet. A generalised definition is, therefore, arrived at that :—

> "A basic substance is one which has a lone pair of electrons which may be used to complete the stable group of another atom ; and that an acid substance is one which can employ a lone pair from another molecule in completing the stable group of one of its own atoms."

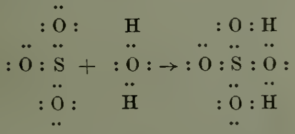
Interesting examples of this are the union of boron trichloride with ammonia, of sulphur trioxide with water, and of silicon dioxide with water. The two former substances each contain a sextet, instead of an octet of electrons, on the central atom of the group, and the process of "neutralisation" may be represented by electronic formulæ as follows :—

$BCl_3+NH_3 \rightarrow BCl_3{\cdot}NH_3$ or



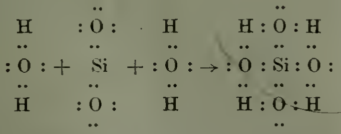
$$\begin{array}{ccccccccc}
 & \cdot\cdot & & & & & \cdot\cdot & & \\
 & :Cl: & & H & & & :Cl & H & \\
\cdot\cdot & \cdot\cdot & & \cdot\cdot\ \cdot\cdot & & \cdot\cdot & \cdot\cdot & \cdot\cdot & \\
:Cl: & B & + & :N:H & \rightarrow & :Cl: & B & :N:H & \\
 & \cdot\cdot & & \cdot\cdot & & \cdot\cdot & \cdot\cdot & \cdot\cdot & \\
 & :Cl: & & H & & & Cl & H & \\
 & \cdot\cdot & & & & & & &
\end{array}$$

$SO_3+OH_2 \rightarrow SO_3{\cdot}OH_2$ or



$$\begin{array}{ccccccc}
 & \cdot\cdot & & & & & \\
 & :O: & & H & & :O:H & \\
\cdot\cdot & \cdot\cdot & & \cdot\cdot & & \cdot\cdot\ \cdot\cdot\ \cdot\cdot & \\
:O: & S & + & :O: & \rightarrow & :O:S:O: & \\
 & \cdot\cdot & & \cdot\cdot & & \cdot\cdot\ \cdot\cdot & \\
 & :O: & & H & & :O:H & \\
 & \cdot\cdot & & & & \cdot\cdot &
\end{array}$$

$SiO_2+2OH_2 \rightarrow SiO_4H_4$ or



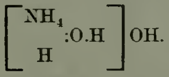
$$\begin{array}{cccccccc}
 & & \cdot\cdot & & & & \cdot\cdot & \\
H & & :O: & & H & & H:O:H & \\
\cdot\cdot & & \cdot\cdot & & \cdot\cdot & & \cdot\cdot\ \cdot\cdot\ \cdot\cdot & \\
:O: & + & Si & + & :O: & \rightarrow & :O:Si:O: & \\
\cdot\cdot & & \cdot\cdot & & \cdot\cdot & & \cdot\cdot\ \cdot\cdot\ \cdot\cdot & \\
H & & :O: & & H & & H:O:H & \\
 & & \cdot\cdot & & & & \cdot\cdot &
\end{array}$$

The former of the above definitions is difficult to apply to solutions in a medium such as liquid SO_2, since it is not easy to picture this as a fusible oxide of metallic sulphur. The solvents actually cited by Lewis are indeed all hydrides, in reference to which the current definition of acids and bases as substances which release or absorb protons still holds good. As regards the second definition, it will be observed that, whereas Werner transfers the meaning of the term acid and base to compounds which are commonly regarded as *hydrates*, Lewis' definition has the effect of transferring the term to unsaturated compounds which have been classed hitherto as *anhydrides*. My own inclination on this particular point is to maintain the current view that an acid must be a hydride since otherwise it cannot disgorge a proton ; but that it need not be a hydrate. As regards bases, I should side with Lewis, since he accepts as bases "all substances which have lone pairs of electrons capable of employment in *onium* formation," and so includes ammonia as a base, where Werner (see below) will only accept it as such after adding on two molecules of water.

6. *Co-ordination and Ionisation.* Werner's theory of acids leads to the conclusion that an acid always contains the group ($XH{\cdot}\bar{O}H$), since the anhydro-acid XH only becomes a true acid by annexing the hydroxyl (and thus setting free the remaining hydrogen) of a molecule of water. Similarly he suggests that even a hydroxide-base such as KOH must be regarded as an anhydride, which only becomes a true base by annexing a hydrogen ion from a molecule of water, and so setting free a second hydroxyl group, *e.g.* :—

$$[KOH]+H_2O=\left[\begin{array}{ll} K{\cdot} & \\ & O{\cdot}H \\ H{\cdot} & \end{array}\right]OH.$$

In the same way, he is not content to turn ammonia into ammonium hydroxide, but thinks it necessary to add on a second molecule of water in order to convert ammonium hydroxide into a real base of the formula :—



$$\left[\begin{array}{ll} NH_4 & \\ & :O.H \\ H & \end{array}\right]OH.$$

At this point Werner appears to "part company" from the majority of his chemical colleagues, who have not been attracted by this additional, and apparently unnecessary, complication ; but it is interesting to follow up the idea which he thus foreshadows—namely, that, from an entirely independent point of view, he arrives at a theory of hydrated ions in aqueous solutions.

Even if the modern view be adopted that the crystals of a salt are an orderly aggregate of ions, *e.g.*,

$$\begin{array}{cccccc} \overset{+}{Na} & \overset{-}{Cl} & \overset{+}{Na} & \overset{-}{Cl} & \overset{+}{Na} & \overset{-}{Cl} \\ \overset{-}{Cl} & \overset{+}{Na} & \overset{-}{Cl} & \overset{+}{Na} & \overset{-}{Cl} & \overset{+}{Na}\ \text{etc.} \end{array}$$

it still remains to discover why these ions are so easily separated from one another when the salt is dissolved by water, I have long advocated the view that in aqueous solutions this separation must be effected by the intrusion of molecules of water, and in conjunction with Mr. W. R. Bousfield I have published papers (*Trans. Faraday Soc.*, 1905, **1**, 197 ; 1907, **3**, 132) in which this idea of a "watery atmosphere" round the ion was developed. On general grounds it might be urged that gaseous ions do actually tend to condense moisture around them, as in the fascinating experiments of C. T. R. Wilson ; but even this would hardly account for the displacement of an oppositely charged ion by neutral molecules of water. Werner's theory brings into play, however, a definite chemical force, namely, that which under favourable conditions leads to the formation of co-ordinated ammines and co-ordinated hydrates. Thus it is at least clear that he would have us believe that a cobaltic ion in aqueous solution would immediately acquire an envelope of six water molecules. Since, however, ionisation is equally developed in salts of the alkali metals, one must suppose that the phenomenon is not confined to the narrow group of transition-metals, but that the co-ordination of water molecules to form a watery atmosphere must be a common property of positive and negative ions in solution. This suggestion implies, however, a definite break from the type of formula put forward by Werner, since he treats the *oxygen* as the central atom of the complex kation of potassium hydroxide, and of the hydrated ion formed by neutralising this with acids, and, moreover, writes a formula which assigns to oxygen the unusual co-ordination-number of three. He also appears to limit the hydration of the potassium ion to a single molecule of water, which could scarcely suffice to create a "watery atmosphere" around it. It will however, be of interest to see whether any experimental support can be found for the view, which is suggested by a perusal of Werner's book, that hydrated ions in aqueous solutions may tend to carry definite numbers of molecules of water, *e.g.*, 4, 6 or 8, etc., to correspond with the numbers that can be grouped symmetrically round the naked ion. If so, a definite link will be established between the physico-chemical study of hydrates in solution, and the more purely chemical study of molecular compounds, which is the principal feature of Werner's work.

7. *Summary.* (*a*) The uniqueness of hydrogen is emphasised by the difficulty of devising for a naked proton a stable electronic system corresponding with that used to represent the electrovalency of other ions. (*b*) Hydrogen ions may be expelled from an acid by the addition of molecules of water to a complex anion, just as chlorine ions are expelled by ammonia in typical penetration-compounds. (*c*) This relation between hydration and ionisation is in accord with the hygroscopic character of strong acids.

The General Chemical Company of New York has given $5000 to the Cavendish Laboratory, Cambridge, to promote research work, and the British Thomson-Houston Company has also given £250 for a similar purpose. Appreciative letters were sent with the gifts, recognising the valuable work which is being carried on under Prof. Sir E. Rutherford in the Cavendish Laboratory.

SOME ASPECTS OF THE FUEL PROBLEM*

By C. H. LANDER, D.Sc., M.I.Mech.E., A.M.Inst.C.E.
Director of Fuel Research

In these days, when knowledge is so highly developed, we are apt to concentrate on a single problem, and to lose our general balance in devotion to that problem. It is always helpful if one can look round and take a broad general survey of the whole fuel problem as it affects Great Britain at the present time. The sciences most intimately concerned in the broad fuel problems are engineering, chemistry and physics. No man exclusively a physicist, a chemist or an engineer can deal properly with these problems. Thus, for successful working, the chemist, important as he is, must have sympathy with, and insight into, the point of view of the engineer and the physicist.

Later on I shall consider a few of the problems which have been selected by the Fuel Research Board for immediate investigation. The Board always welcomes any suggestions for extension of these investigations, or constructive criticism upon the methods employed in attempting to solve them, and the results which have been obtained. I am glad to be able to lay before you some of the results of the recent work carried out by the Fuel Research Board, as it appears that there is some misapprehension as to the type of work being carried out and the results obtained.

Fuel is used for a large variety of purposes, but they all fall into two categories:—

(1) The development of mechanical power at some particular spot; or

(2) The introduction of heat into some substance, also at a particular spot. In no case can the whole of the energy contained in the raw fuel, as it occurs in its natural state, be utilised, and in most cases only a very small percentage can be utilised.

The problem of efficient utilisation depends not only on the efficiency of the conversion of the heat energy or of the transference of the heat to some object, but also on the cost of transporting the energy to the point of application, and in many cases on the ease of control. For example, the coal as it occurs in the seam underground is useless until it has been moved to some point where its energy can be usefully applied.

Before utilising the energy in the coal it may be desirable to convert it into some other form of fuel, such as gas, coke or oil, or into some other form of energy, such as electrical energy, the object being to increase the ease of transport or of application, or both. Incidentally, it may be possible in the process of conversion to recover by-products some of which are available as fuel, whilst others are valuable for other purposes, *e.g.*, as fertilisers. The same sort of considerations apply to other forms of raw fuel.

---

* Contribution to the Discussion on the "Fuel Problem," held by the Birmingham and Midland Section on January 23 and February 6.

The value of any form of fuel or energy depends, therefore, on its "availability" in the broadest sense of the word, and this again depends upon the facility with which it can be transported to the point of application, and on the efficiency and convenience with which it can be utilised at that point.

The importance of the "portability" of the fuel naturally depends on the distance between the source (mine, carbonising plant, etc.) and the point of application, and the transport facilities available. The efficiency with which it can be utilised depends upon the purpose for which it is required and on the scale on which it is employed. As these factors may vary to almost any extent, there can be no "best" method for the utilisation of any given form of natural fuel or energy. The economic value of a process of conversion from one form to another depends not only on the thermal efficiency of the process, but also on the capital charges due to the plant, etc. required and the cost of the labour and supervision involved. It does not follow that the process which in any given case gives the highest thermal efficiency gives also the highest economic efficiency.

The value of the different forms of fuel either natural or derived, depends also on the convenience of use and ease of control during use. In providing illumination it does not follow that the most efficient conversion of the heat of the coal into light is the most economical method, as it may necessitate producing light when it is not wanted. The efficiency as usually measured deals only with the total light produced, and takes no account of whether all this light is actually required or not. Where intermittent power is required, heavy standing charges may be incurred with a method of conversion which is otherwise economical, and a less thermally efficient method may be advantageous, if it makes possible the storage of energy or the adoption of some method of distribution which enables the diversity factor of separate intermittent loads to be utilised.

In considering the utilisation of fuel, it must always be remembered that all the heat originally in the fuel appears again somewhere as heat, and the control of the points where this appears may be of considerable economic importance.

I will now consider some of the problems which the Fuel Research Board has selected for immediate investigation.

Coal Survey

The programme of the Fuel Research Board as laid down at its inception in 1917, followed two broad lines:—

(1) A survey and classification of the coal seams in the various mining districts by means of chemical and physical tests in the laboratory; and

(2) An investigation of the practical problems which must be solved if any large proportion of the raw fuel at present burned in its natural state is to be replaced by the various forms of fuel obtainable from coal by carbonisation and gasification processes.

It was at first believed that the survey might be carried out in advance of the second line of inquiry, but further consideration, and the trend of events, forced the Fuel Research Board to the conclusion that the two were absolutely interdependent, and must be dealt with side by side. In point of fact, owing to unstable conditions in the coal industry during and since the war, the work of the Survey has to a certain extent lagged behind the other branches of the programme of the Board. Although a survey of our national coal resources had been advocated for many years, the Board always believed that there was great danger that such a survey might result in an undigested mass of samples and chemical analyses which would be of little real assistance to those whose duty it is to utilise our strictly limited coal resources to their fullest extent. The Board, therefore, approached the subject from the point of view of both producer and user, and concluded that the more practical side of the work can be most effectively carried out with the help of local committees, in which colliery owners, managers and consumers are associated with the representatives of the Fuel Research Board and of the Geological Survey, together with outside scientific representation.

The first of these local committees is now actively at work in the Lancashire district, where the local association has been recognised for this purpose as the representative body in charge of the work in their district. The committee began work by the correlation of reliable information concerning one of the most important seams in the district. Where gaps have occurred in the information already available, experimental work has been carried out on a small scale.

The points brought out by this preliminary survey indicated the lines upon which work has been undertaken on a much larger scale, to determine the processes to which the coal can best be submitted in order to obtain certain results. Experimental work, involving the gasification of more than 500 tons of this coal in vertical retorts has recently been completed at H.M. Fuel Research Station. The commercial value of the work can be gauged from the fact that a group of firms commercially interested placed at the disposal of the Board, free of charge, some 300 tons of the seam, in order to assist the work. Having thus obtained some information as to the best method of carrying out such an inquiry, the local committee is now engaged in a similar inquiry into another well-known seam, which has hitherto presented great difficulties both as regards its working and marketing.

The Board is now about to form the second of these local committees in another coal mining area, where considerable interest has been shown in the work of the first committee.*

Methods of Sampling and Analysis

In preparation for the organisation of the first line of research work, it was decided that an experimental study was necessary of the methods of examination of coal samples usually adopted in laboratories. The scientific committee appointed to consider the question has been at work for some time, and is about to present an interim report, based on a large amount of experimental work, and recommending the methods they consider the best. These recommendations will be adopted by the Board for the survey work, and it is hoped that analysts and others interested in the sampling and analysis of coal will also adopt these methods as standard. This will make analyses carried out by various workers more comparable than they have been in the past.

The analysis of each coal which passes through H.M. Fuel Research Station is added to the permanent registry which is kept in the Survey Department of the Board. Maps and a filing system are provided, so that all samples sent to the Station, as well as all bulk samples passing through for experimental purposes, can be definitely located and registered.

The Fuel Research Board came to the conclusion at a very early stage that, apart from investigation into the generally accepted methods for coal analysis, it was necessary to work out some system for investigating the suitability of coal for low temperature carbonisation. A test was accordingly elaborated which, by direct weighing and measurement, gives the yields of the products which result from carbonisation at any definite temperature. (*Cf.* "The Assay of Coal for Carbonisation Purposes: A New Laboratory Method," Fuel Research Board, Technical Paper No. 1, 1921.) Experience on larger scale work shows that the results obtained with this small apparatus are comparable with those resulting from large scale working.

Gas Standards

In dealing with the work of the Fuel Research Board, reference was made to circumstances which rendered it desirable that the work coming under each of the two headings of the programme should be carried on side by side. This was partially brought about by the reference to the Fuel Research Board of the whole question of gas standards, by the Government Departments concerned in the administration of the various Gas Acts. The results of the investigation by the Fuel Research Board were given in the booklet recently issued by the Department of Scientific and Industrial Research and entitled the "Therm." It is hardly necessary to state the recommendations of the Board, and it will suffice to say that only by the system of selling gas by its thermal content was it possible both to protect the consumer and to afford to an industry using something like 20 million tons of coal per annum, a freedom which would render it possible to select in each case those methods which would produce the most economical results, both from the point of view of coal economy and cheapness of gas to the consumer, having due regard to the particular circumstances of each undertaking. That there is great scope for this development is evident from the fact that, according to practice which has been well established in the past, only some 21 to 24 per cent. of the total potential thermal units of the coal are sold in the form of gas. Whether it is actually desirable to increase this percentage in any particular case depends upon local conditions and upon the commercial value of the other products.

The interdependence of the two lines of inquiry outlined in the programme of the Board was also emphasised by a variety of other influences during the past 15 years. Amongst these have been the demand for cheaper and more ample supplies of electricity, home supplies of fuel oil for the Navy, motor spirit and oil for transport and air services, and for smokeless domestic fuel, the demand in the last case being due to the rapid growth of public opinion on the subject of smoke prevention.

Steaming in Vertical Retorts

The experimental work upon which were based the recommendations of the Fuel Research Board on Gas Standards naturally led to an inquiry into the proposal to convert more of the potential heat units contained in coal into a good and saleable gas. The direction in which general practice was proceeding was the utilisation of higher temperatures during carbonisation and the admixture of water gas made from a portion of the coke. The most recent step was to introduce steam at the lower end of vertical retorts and so convert some of the carbon into water gas within the retort itself. This method was, in fact, a resuscitation of work carried out by Sir George Beilby during his association with the Scottish shale industry in the early 'eighties, and which had recently come into prominence on account of the valuable test work which had been carried out by Mr. Blundell, Mr. West and others. Small percentages only of steam had, however, been used by the experimenters, since their aim had obviously been to keep the carbonic acid in the gas under 4 per cent. Accordingly, early in 1918, a setting of four retorts capable of carbonising 10 tons of coal daily was designed and erected by West's Gas Improvement Company at the Fuel Research Station. The results obtained were given in the first section of the Report of the Fuel Research Board for 1920–21. Further work on typical coals is being carried out at H.M. Fuel Research Station, these investigations having been undertaken at the direct request, and partially at the expense of, certain important gas companies. Work has also been in progress at the Station on the manufacture of water gas, the main results being that with a normal water-gas plant, it is possible to obtain a slightly greater thermal efficiency by working on the Dellwik system, where a thin fuel bed is used, with a blow to carbon dioxide, but that in a normal plant this gain in thermal efficiency is obtained at the expense of the output. If a plant were specially designed to obtain this higher thermal efficiency, it would require greater floor area for the same output. Hence it is not necessarily commercially economical.

---

* The second local committee has since started work in the South Yorkshire area.

Low Temperature Carbonisation

The investigation of low-temperature carbonisation followed naturally upon the inquiry into the possible home sources of oil supply for the Navy, which were first exhaustively examined by Lord Fisher's Commission during 1912–13, while emergency inquiries were conducted during the war with the same object. None of these later inquiries added materially to the information collected and verified by the Fisher Commission, and the urgency of the question has been emphasised since the Armistice owing to the rapidity with which oil is replacing coal in the Navy and mercantile marine.

There are important considerations which cannot be ignored in dealing with the wider problem of the replacement of raw coal by other forms of fuel. The industries that manufacture gas and coke have for their primary object the supply of these products to definite bodies of consumers. Careful consideration will show that the present coal-distilling industries cannot be regarded as the source of greatly increased supplies of fuel oil. The only means by which fuel oil could be obtained in large quantities would be by the carbonisation of the bulk of raw coal used for domestic purposes. To do this it would be necessary that the domestic consumer should be supplied with an alternative form of fuel of suitable quality and price. The only means by which the maximum quantity of liquid hydrocarbons can be conserved in a carbonisation process is by the distillation of coal at a minimum temperature. One of the most important products is a coke containing from 8 to 10 per cent. of volatile matter. This material forms an excellent and absolutely smokeless fuel for domestic purposes, and can if required be burned under boilers or used as a fuel in suction gas producers. At a temperature of 600° C. the principal products of carbonisation amount to 70 per cent. coke, 6 per cent. oil and 9 per cent. gas. Put in another form—from each ton of coal we can obtain about 2½ galls. motor spirit (1½ from the gas and 1 from the tar oil), 13 galls. fuel oil, and between 3000 and 4000 cub. ft. of rich gas and 14-15 cwt. of semi-coke. In order to obtain trustworthy data for the method of treatment and the products obtainable from various classes of coal, the Fuel Research Board installed a bench of 9 horizontal steel retorts for experimental purposes. A large amount of experimental work has been carried out in these retorts, some of which has been published in the Second Section of the Report of the Fuel Research Board for 1920–21; and investigations have also been undertaken for some of the Colonies.

An important side of this inquiry has been the correlation of the results obtained from the retorts referred to and those yielded by the low-temperature assay. It has been found that, from the appearance of the coke in the low-temperature assay apparatus, it is possible to deduce the type of coke which may be expected on the large scale. The yields per ton of gas and coke are roughly the same. The yield per ton of oil as obtained from the low-temperature assay apparatus must be multiplied by a conversion factor of 0·6 in order to obtain the equivalent yield in the horizontal retorts. The shape of the rate of gasification curve is also similar in the two cases.

These retorts, having been installed purely for experimental purposes, could not be expected to produce low-temperature fuel and oil at a price which would render the process commercially sound. The chief cost lies in the labour, which is somewhat heavy. Having obtained trustworthy data, the possibility was examined of producing an apparatus which would do mechanically what was done by hand in the experimental horizontal retorts. During the last two years extensive experiments have been conducted in this direction, using a machine which consisted of a large oven, containing a cage made up of a number of shelves, one above the other. The trays of coal to be carbonised could be placed on these shelves by suitable charging apparatus. This method has, however, been abandoned for the time being, since other lines of inquiry have developed which appear to be more promising. The main difficulty was that the working parts exposed to the temperatures necessary for carbonisation tended to get out of register, and to make the upkeep cost rather heavy. The Fuel Research Board still believes, however, that for low-temperature work it is not necessary to provide expensive fireclay retorts.

Cast iron, or even mild steel if not too highly stressed, is likely to afford a material from which retorts for this purpose could be manufactured, and from which a long life might be expected. Other experimental work has been carried out at the station by carbonising at low temperature in the vertical retorts, from which interesting data have been obtained bearing upon the conduction of heat through masses of coal at lower temperatures than those generally adopted in gas practice.

Work on low-temperature carbonisation is being carried out by other outside groups, with which in many cases the Board is in close contact. The results are promising, but the Fuel Research Board would hesitate to say that commercial success has yet been obtained.

It may be of interest if I indicate briefly the lines upon which the Board are now working. These may be said to consist of the subjection of the crushed coal to a temperature which approaches the fusing point of the coal. At this stage the coal is briquetted and fed into simple iron vertical retorts whose design is based on Scottish shale practice.

Power Alcohol

The question of the use of alcohol as a fuel for internal combustion engines has been studied during the last few years, both in this country and in France.

Acting on the recommendation of the Interdepartmental Committee on Fuel for Motor Transport, which reported in June, 1919, an organisation in charge of Sir F. Nathan was established under the Fuel Research Board to investigate the production of alcohol within the Empire. The author is indebted to Sir Frederic Nathan for the following short account of the alcohol position within the Empire. At the present time the only methods of proved economic value for producing alcohol are fermentation processes which utilise sugar obtained directly from the plant, *e.g.*, molasses, or from starch, *e.g.*, grain of all kinds. Power alcohol is being made on a comparatively small scale in this country from molasses, and is used in conjunction with benzol and/or petrol as a fuel for internal combustion engines. Its production from vegetable materials in this country has been thoroughly investigated, and the conclusion has been arrived at that it would not be economically possible on any considerable scale, owing to insufficient acreage, the high cost of cultivation, harvesting and transport, the high cost of manufacture, and the fact that the most suitable raw materials are also important foodstuffs.

Atteution has also been paid to power alcohol production in the Dominions and Colonies, where most of the conditions are more favourable than those in the British Isles. Their liquid fuel requirements are relatively small, land is more generally available, labour is comparatively cheap and the climates are just what is required for growing very suitable vegetable raw materials. There are possibilities in this direction. There are, moreover, in the tropical and semi-tropical parts of the Empire vast quantities of vegetation of little or no commercial value, which might be commercially possible sources if alcohol could be produced from the cellulose of the plant by converting it into fermentable matter by cheap and simple chemical or bacteriological processes. The work on the direct production of alcohol from cellulose materials by the action of micro-organisms presents considerable difficulties, and progress has so far not been sufficient to enable any opinion to be expressed as to the possibilities of success.

The mechanism of the acid hydrolysis of cellulose is being studied with a view to determining the optimum conditions, and a method of fermenting the resulting products is being investigated, especially as regards the pentoses which comprise the bulk of the products of hydrolysis. If these products can be successfully fermented (and considerable progress has been made in this direction), it might result in the establishment of a commercial process for treating tropical or semi-tropical vegetation.

The Department of Scientific and Industrial Research has subsidised the work of the Engineering Sub-Committee of the Empire Motor Fuels Committee on the use of alcohol and other liquid fuels in internal combustion engines, and a valuable report by the Committee was published in the *Times Engineering Supplement*, on May 20, 1922.

The Department assisted the Commissioners of Customs and Excise in introducing sections into the Finance Acts of 1920 and 1921 giving legislative sanction to the use of alcohol for generating mechanical power, removing the surtax on imported spirits, increasing the drawback on home distilled spirits, and giving powers to the Commissioners to make regulations. Those already issued enable alcohol for power purposes to be imported and handled with the minimum of trouble and expense, and after it has been denatured and mixed with other liquid fuels in accordance with the regulations, to be sold and used without restriction.

As regards synthetic production, the possible raw materials are calcium carbide, the ethylene in coal gas from gasworks and coke-oven installations, and from water gas mixtures. Large scale production from calcium carbide is unlikely within the British Empire, and the processes for making it from ethylene and water gas mixtures are still in the experimental stage. Time does not permit me to deal with the remaining activities of the Fuel Research Board. Briefly, these activities relate to the winning and utilisation of peat, the suitablity of mixtures of fuels for internal combustion engines, investigation into the fundamentals underlying domestic heating, and the utilisation of special fuels in boiler furnaces.

FORTHCOMING EVENTS

Nov. 14. ROYAL INSTITUTE OF PUBLIC HEALTH, The Lecture Hall, 37, Russell Square, W.C. 1, at 4 p.m. "The Extravagance of a Smoke-Polluted Atmosphere," by W. B. Smith, O.B.E.

Nov. 15. THE INSTITUTION OF MINING AND METALLURGY, Burlington House, Piccadilly, W. 1, at 5.30 p.m.

Nov. 16. INSTITUTE OF METALS, *Swansea Local Section*, The Metallurgical Department, University College, Singleton Park, Swansea, at 7.15 p.m. "The Density of Alloys," by Prof. T. Turner, M.Sc.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on October 12, 1923, the President (Dr. E. F. Armstrong, F.R.S.) being in the chair.

A cordial welcome was given to the new members of Council attending for the first time.

A letter signed by the presidents and other officials of the Chemical Society and the Society of Chemical Industry regarding the proposed establishment of a Bureau of Chemical Abstracts, under the management of a joint committee consisting of four representatives of each society, was submitted. The proposal was approved, and Dr. E. F. Armstrong, F.R.S., Mr. Julian L. Baker, Mr. E. V. Evans and Sir Wm. J. Pope, F.R.S., were nominated as the Society's representatives on the joint committee.

A further letter signed by the same officials urging the desirability of giving facilities to the members of each society to acquire the publications of the other society, and of offering further inducements to chemists to join both societies, was also considered. The Council approved the principles involved, and remitted the discussion of details to a committee consisting of the President, the Hon. Treasurer, Mr. J. L. Baker, Mr. C. S. Garland, M.P., Prof. J. W. Hinchley, Sir Wm. J. Pope, F.R.S., Mr. Edwin Thompson and Mr. W. J. U. Woolcock.

It was reported that letters had been received from Prof. C. F. Chandler, Prince Ginori Conti, M. Paul Kestner, and Sir Dorabji Tata, expressing their gratification at being elected honorary members of the Society.

The report of the honorary treasurer was discussed, and for the purpose of fully considering all possible means of effecting economies certain suggestions were remitted for consideration to the committee appointed above.

The reports of various committees of the Council were submitted, and 36 new members (Home 25, Overseas 11) were elected.

The Publications Committee and the Executive Committee for *Chemistry and Industry* were continued in office until the end of the present year, by which time it is hoped that the proposed Bureau of Abstracts and other arrangements will have been decided upon.

The present representatives on outside bodies (see *Journal*, 1922, p. 560 R., and 1923, page 275 T) were all reappointed, except in the case of the British Association Fuel Economy Committee, now non-existent.

The British Empire Sugar Supply (Technical) Committee was re-elected, and Mr. Julian L. Baker agreed to act as chairman in place of Prof. A. R. Ling, resigned.

An application by the Birmingham Section to admit associates was agreed to.

A committee representative of the membership of the Society in India was appointed to consider fully the practicability of forming and carrying on proposed sections of the Society in Bombay and Calcutta.

With regard to the British Empire Exhibition, 1924, it was reported that considerable progress had been made with the Scientific Exhibit. The joint committee on which the Society is represented is working in co-operation with the committee of the Royal Society, and it has been agreed that the joint committee will undertake the exhibit of Pure Chemistry, and the Royal Society the exhibit embracing all the other sciences. A very comprehensive scheme of classification of the chemistry exhibit has been drawn up, and practically every scientist of note in the country has promised help. The work of the Publicity Committee under the chairmanship of the President has begun, and it has been arranged to publish a series of about 12 pamphlets written in popular language dealing with the scientific exhibit. It has also been agreed to publish a scientific record of the state of chemistry at the time of the Exhibition, as illustrated by the exhibit. It is estimated that the cost of the scientific exhibit will be about £5000, of which one-half has already been promised.

A preliminary report as to the arrangements for organising the Chemical and Physical Sections of the World Power Conference was received from the Chemical Engineering Group.

Arrangements for the dinner of chemists were reported; and the date of the next Council meeting was fixed for Friday, November 9.

YORKSHIRE SECTION

Dr. L. L. Lloyd occupied the chair at the opening meeting held at the Queen's Hotel, Leeds, on October 22, when Dr. N. M. Comber read a paper on "The Colloidal Constitution of Clays and Soils."

At the outset the author said that the conclusion arrived at in a previous communication that soil particles were protected by an emulsoid coating, had been confirmed by further experimental work. The facts that there was no characteristic rate of evaporation of moisture from clay, that lime alkalinity increased flocculation and that the only other substances capable of doing this were the phosphates of calcium, aluminium and iron, were held to support this conclusion. The increased solubility of clays after gentle ignition was explained by the fact that, owing to dehydration, an increased surface was presented to the attack of the acid. The fact that a neutral clay after gentle ignition showed increased absorptive power for lime was explained in a similar manner.

In discussing the absorption of electrolytes the facts that bases are absorbed very quickly, and that only acids like oxalic and phosphoric are capable of absorption, were examined. Lime absorption was increased by preliminary acid treatment, and if the results were plotted (absorptive power for lime and acid per cent.) it was found that a maximum amount was quickly reached which rarely exceeded seminormal, and then remained constant. This was explained on the assumption that lime was absorbed only at the surface. It was pointed out further that the only acids absorbed were those which formed insoluble salts of calcium and aluminium and this suggested that absorption was a precipitation effect. Russell and Prescott's work in this connexion was examined, and it was held that their results did not show conclusively that the effect was due to adsorption. The supposed amphoteric nature of clay was discussed, and the statement was made that this had never been proved, clay always behaving as electro-negative.

GLASGOW SECTION

The opening meeting of the session was held on October 26 in the Institute of Engineers and Shipbuilders, Elmbank Crescent, Glasgow, when the chairman, Mr. W. E. Moodie, F.I.C., read a paper entitled "The Industrial Chemist."

The speaker introduced his subject by saying that the works chemist was supposed to know something about everything and everything about something, and illustrated this by outlining the training and progress of the industrial chemist from the cradle to the grave, emphasising also the necessity for some knowledge of engineering and electricity. Regarding the allegation frequently made that the chemist was seldom if ever a competent business man, Mr. Moodie said, "Let us not take this lying down; it is not judgment the chemist lacks (in business matters), but application." He believed that the mind which could master and unravel the intricacies of complicated chemical changes was surely of sufficient calibre to comprehend and appreciate business principles; and if the chemist did not concern himself with financial aspects it was because at certain stages of his work these did not call for consideration.

Mr. Moodie referred to the need for constant and sustained study throughout the industrial chemist's career, and laid stress on the value to those starting on their post-college careers of membership of some chemical society such as our own.

In the course of the discussion Prof. G. G. Henderson expressed the opinion that most chemists could pick up enough engineering knowledge to carry them through, but it was extremely seldom that a man with a real bent for mechanical science could acquire even a passable practical knowledge of chemistry.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The third meeting of the Société de Chimie Industrielle opened on October 21 in Paris by a brilliant reception followed by a social evening with artistic entertainment. The next day the formal opening was carried out by Monsieur Dior, Minister of Commerce. Prof. Menozzi, of Milan, spoke on the practical value of soil analysis in the light of our present knowledge, and the various technical groups began the work planned for them. The meeting ended with visits to factories and excursions. Amongst the foreign delegates were Prof. H. E. Armstrong, F.R.S., Sir J. Russell, F.R.S., Prof. J. T. Hewitt, F.R.S., Dr. S. Miall, Mr. Lomax, Mr. A. R. Smith, Dr. H. Levinstein and Mr. O. Lucas. The foreign delegates were received on October 21 by the "Bienvenue Française," which offered them a dinner, followed by an entertainment.

A more detailed account of the meeting will be furnished later by Monsieur M. Deschiens, general recorder of the meeting.

THE INSTITUTION OF PETROLEUM TECHNOLOGISTS

The meeting held on October 9 at the Royal Society of Arts, was devoted to a paper presented by E. H. Cunningham-Craig, B.A., F.G.S., entitled "Recent Researches bearing upon the Origin of Petroleum." After discussing the inorganic and organic theories of the origin of petroleum, the author observed that the inorganic and volcanic theories of origin did not find much acceptance nowadays, and of the organic theories that of animal origin was chiefly supported by chemists, and that of vegetable origin by geologists.

It was becoming evident that coal and petroleum had definite relations to each other, as was shown in Trinidad, Venezuela, Burma, and particularly Rumania. Much evidence from Great Britain was also brought to light during the war when the D'Arcy well was drilled, on the theory that oil shale denoted petroleum that is dead and buried, but that beneath the oil shale series some free petroleum might still exist. The drill proved the theory was right, for free petroleum was found within ten feet of the depths predicted.

The author next considered the importance of the work of Bergius on the hydrogenation of coal, and said it was claimed that an oil "almost identical with crude petroleum" could be obtained by treating coal containing a fair percentage of volatile matter with hydrogen at a very high pressure, and at temperatures up to 850° F., with the result that an exothermic action began, and part of the solid fuel was liquefied. It would be of interest if some supporters of the animal theory of origin would try hydrogenation experiments with deposits containing, or supposed to contain, animal matter, to find whether liquids indistinguishable from petroleum could be obtained.

The bearing of the evidence afforded by the cannel coals upon the formation of petroleum was next considered, and an account was given of recent work on the torbanites, which were merely cannels containing sufficient colloidal inorganic matter that had been subjected to the necessary pressure. The evidence suggested that if oil shale denoted petroleum dead and buried, torbanites denoted petroleum still-born. The evidence for the origin of oil from vegetable matter was as clear as could be desired.

In the ensuing discussion, Dr. Dunstan could not admit that laboratory methods of producing hydrocarbons from fatty acids were applicable in nature; he did not agree that the liquids obtained from coal by the Bergius method were similar to petroleum and suggested that there were several modes of origin.

STREATFEILD MEMORIAL LECTURE

The Streatfeild Memorial Lecture was delivered by Mr. E. M. Hawkins, F.I.C., at the Finsbury Technical College on October 25 on the subject of "Analytical Chemistry."

After reference to the value of the training which he and his former fellow-students had received at the College under Meldola, Streatfeild and Castell Evans, the lecturer emphasised the importance of a knowledge of physics, mathematics and physical chemistry to the present-day analyst and consultant. First among the qualifications required in the analyst were accuracy and reliability, to which should be added the ability to decide to what degree of accuracy his results attained. He should also have a due sense of his responsibility in carrying out his work, especially when extensive repetition gave to it an appearance of drudgery. Secondly, there was the need for rapidity to be associated with accuracy, as few students realised the speed of manipulation which would be required of them when they obtained a post after leaving college.

Thirdly, it was of great importance that the student should cultivate the gift of expressing his results suitably in a report, for much good experimental work was marred by the inability of the chemist to write up his results in such a way that the bearing of the work could be properly appreciated by those who read the report. It was necessary that the chemist should not be easily moved from an opinion formed after careful consideration of results obtained by honest and patient investigation.

In conclusion the lecturer stated that of the three classes of men practising chemistry, works chemists, public analysts, consultants, the first-class would greatly outnumber the public analysts when trade revived, whilst consulting chemists would be men of wide experience and high attainments who would be called upon by manufacturers to solve their problems and should be highly remunerated for such work.

CORRESPONDENCE

ELLIS'S PRACTICAL BACTERIOLOGY FOR CHEMICAL STUDENTS

Sir,—In your issue of October 26, Prof. Ellis takes exception to a review of his book by me in your issue of October 5, 1923, and queries my right, as a medical man, to review a book written by a biologist for chemical readers. The fact that the editorial staff passed on this book to me for review is, I think, sufficient evidence of my experience as a bacteriologist to give an opinion in regard to it.

In regard to the question of malice alleged by Prof. Ellis I have never, to my knowledge, met Prof. Ellis, nor have I ever heard of him until his book appeared, so wherein can the question of malice arise? Prof. Ellis may yet come to regard me as his friend if he will read my criticism as it is meant and produce a book for which I believe an opening is present.

The author appears to think that my review was directed from a standpoint of purely human bacteriology. This, on the ground of wide bacteriological experience, I deny, but I would point out that bacteriological technique is very similar, whether it affects the works chemist, the botanist, the veterinary surgeon or the medical man, but in view of the life and death responsibilities dependent upon accurate diagnosis in human bacteriology no loose methods of technique can be considered. As an example, may be quoted the use of broth by Prof. Ellis as a basis for fermentation tests. Broth as usually prepared from meat contains glucose which has resulted from the breaking down of stored glycogen present in the muscles. This percentage of glucose always present will be quite sufficient to invalidate the reactions with other sugars and would lead to false classification.

Whatever Prof. Ellis' opinion may be about his princely *B. Megatherium* purchased for 1s. I deny that continual use with this organism would train a chemist into a bacteriologist. The difficulties of high-power manipulation are not met by using bacteria requiring low-power lenses, and it is a recognised fact that immersion lenses are a *sine quâ non* of bacteriological teaching other than by kindergarten methods.

Prof. Ellis is also wrong in stating that gelatin will grow 99·9 per cent. of organisms which a works chemist may be required to work with; and in certain climates it is practically impossible to use gelatin to any practical degree. Prof. Ellis states that a chemist must approach bacteriology from the biological side and that presumably a medical man does not do so. I should have thought that Prof. Ellis would have known that a medical student's training is biological from the outset and is biological to the finish, and if it is inadequate that is a fault of his biological teachers.

Prof. Ellis states that he has written his book with the idea in mind of a "young chemist deposited in a factory and having to tackle some trouble that has arisen owing to a microbe having run amuck in the works." Whatever Prof. Ellis may mean by microbes "running amuck in works" I must confess to a feeling of sympathy with that young chemist, if his only armamentarium consists of a low-power microscope, the media recommended by Prof. Ellis, and Prof. Ellis' book.

That I am not alone in this feeling is apparent by the opinion also of your other correspondent —Mr. R. F. Hunwicke—whose letter appeared as a footnote to Prof. Ellis's own letter.—I am, Sir, &c. Arnold Renshaw

THE BRITISH DYESTUFFS INDUSTRY

Sir,—Our attention has just been directed to a letter published in your issue of the 21st ultimo, from Mr. C. M. Whittaker, in which he states: "the Direct Cotton Colour Sky Blue FF. at 12s. 3d. is twelve times its pre-war price."

We beg to state that we were supplying this product at the date of his letter and are doing so to-day at less than half the price mentioned by him.—We are, Sir, &c.,

The Clayton Aniline, Co., Ltd.

Clayton, Manchester
Oct. 29, 1923

ANTI-KNOCK GASOLINE

Sir,—In your current issue a paragraph appears on p. 1029 advocating the addition of tetra-ethyl lead and carbon tetrachloride to motor fuel. The device may give excellent results as far as economy of fuel is concerned, but the possible danger to health caused by the emission of finely divided or volatile lead compounds in public thoroughfares ought not to be left out of account.—I am, Sir, &c.,

F. Shedden

ON A PROPOSAL REGARDING CANAL CONSTRUCTION

Sir,—Possibly it is for shame of the sinful neglect of our waterways, natural and artificial, that the subject of internal water carriage in the country is hardly ever mentioned.

Whenever this problem is taken up it must be with a different outlook from that we should have had 25 or 30 years ago. If the canals are to be given life they must be organised for quick transit in keeping with other modes of carriage. This means that most canals must be wider and deeper and, more important still, constructed so as to resist the " wash " of propellers or other quicker means of traction than horse haulage.

I would venture to suggest that it would be an improvement in many cases, especially where widening is difficult or impracticable, to have a lining of sheet metal—complete or partial—so arranged at the bank, a little above water-level, that it curves over inwards towards the water to resist and throw back the " wash " wave of the boat. Moderately thin sheet iron, possibly protected by cement or pitch, would last a very considerable time, and would not be difficult to secure to the sides of the canal to the depth affected by the rush of water.

There are several details, as strength of sheet metal, means of protection of same against rusting, attachment of the metal lining and so on, which present no serious difficulties. The thing is, we must have quick and convenient water carriage and that soon. The comparison of the cost of water carriage per ton mile with that of any other form of carriage will settle this point.

The present time seems a favourable one to take this suggestion into consideration.—I am, Sir, etc., W. R. HODGKINSON

Blackheath

PERSONALIA

Dr. Earle F. Whyte, M.A., of Clark, has been appointed to succeed the late Dr. John Waddell as professor of analytical chemistry at Queen's University.

M. R. Walker has been appointed as special expert in charge of the Non-ferrous Division of the Metals Section of the U.S. Tariff Commission.

Monsieur J. L. Breton, director of the French National Office for Scientific and Industrial Research and Inventions, has been appointed president of the Higher Commission for Inventions in place of the late Monsieur Violle.

* * *

From Mulhaus the death is announced of Monsieur E. Dollfus, a well-known manufacturer.

On August 17 the death took place of E. Mattirolo, a well-known Italian geologist to whom was due the discovery of bauxite in Italy, and numerous chemical and micrographic researches on Italian rocks.

Prof. S. P. Sharples, who died on August 20 at the age of 82, was one of the chartered members of the American Chemical Society, as well as a member of the Society of Chemical Industry since 1884. His work covered a wide field, ranging from problems of spectrum analysis to questions relating to timber, fat and soap manufacture.

NEWS AND NOTES

GENERAL

New Potash Deposit in Czechoslovakia

According to the Gazette de Prague large deposits of potash, estimated to contain millions of tons, have recently been discovered in Czechoslovakia. The discovery is said to have been made by a geologist, Prof. Jahn, and a chemist, M. Prokes.—(*Cham. Com. J. Sept.* 14, 1923.)

Metallurgy in Belgium

In August 36 blast furnaces were alight, and the production reached :—198,929 metric tons of cast iron; 206,805 t. of steel; 5800 t. of castings; 173,148 t. of finished steel, and 17,320 t. of finished iron. During the same month the output of coal in Belgium was 1,926,000 t. compared with 1,856,570 t. in July. The production of coke was 364,930 t., which is about 71,000 t. higher than the pre-war average production of coke; similarly, the production of coal is about 70,000 t. higher than the pre-war average.

Investigation of Uranium Minerals in the Belgian Congo

It is announced that Prof. A. Schoep, of the University of Ghent, has identified several new uranium minerals, to which he has assigned the following formulæ :—Curite, $PbO \cdot 5UO_3 \cdot 4H_2O$; Kasolite, $3PbO \cdot 3UO_3 \cdot 3SiO_2 \cdot 4H_2O$; Dewindtite, $PbO \cdot 2UO_3 \cdot P_2O_5 \cdot 3H_2O$; Soddite, $5UO_3 \cdot 2SiO_2 \cdot 6H_2O$; Becquerelite, $UO_3 \cdot xH_2O$. A uranotitano-columbate of calcium containing small amounts of rare earth has been designated as Mendeleeffite; the chemical formula has not been established definitely, but the mineral contains approximately U_3O_8 23·5 per cent. and CaO 15 per cent. It is considered as a variety of Betafite but contains no water of crystallisation.

Tasmanian Mineral Yield for 1922

According to the annual report of the Tasmanian Secretary of Mines for the year ended December 31, 1922, the aggregate value of minerals raised during the year was £1,013,415, being an increase of £190,564 on the output of the previous year. The gold won was valued at £15,992; silver, £123,497; lead, £118,257 and copper, £391,535. The Mount Lyell Co. treated a total of 57,287 t. of ore and concentrates, which yielded 5661 t. of blister copper, valued at £416,017. On an average 942 men were employed during the year, and dividends paid by the company from its inception to December 31 totalled £3,894,469. The metal production of the company for the same period was 180,160 t. of copper, 13,083,297 oz. of fine silver, and 378,399 oz. of fine gold. Metallic tin raised in Tasmania in 1922 was worth £112,407, and the osmiridium won was valued at £36,512. The Electrolytic Zinc Co. produced 23,517 t. of slab zinc worth £706,390 at Risdon from 64,401 t. of Broken Hill calcines. The silver-lead output for realisation at Port Pirie contained 2780 t. of lead and 635,701 oz. of silver.

REVIEW

The Electron in Chemistry. *By* Sir J. J. Thomson, O.M., F.R.S. *Pp.* 144. *Philadelphia: The Franklin Institute,* 1923. *Price* $1·75.

Chemical journals are now so full of articles and reviews dealing with the electronic theory of chemistry that a discussion of the principles of the application of the theory is unnecessary. A review of such a book as this for a body of such readers cannot attempt to do more than indicate what sort of book this is, and the sort of information which may be found in it. All those who read chemistry are already familiar with the fact that the Master of Trinity can think clearly and express himself clearly. The book consists of five lectures delivered in April, 1923, at the Franklin Institute, Philadelphia. It is worthy of that memorial of a remarkable man who is credited with having snatched lightning from the sky and the sceptre from a king. The first lecture deals with the problem of arranging in space a number of electrons in stable equilibrium around a positive charge without describing orbits around it. It treats this subject from first principles and shows how the results agree with the evidence afforded by positive rays and Bragg's measurements of the radii of atoms. The second lecture deals with the octet theory and its application to various chemical compounds; the third with residual affinity and Werner's co-ordination numbers, with a short but highly suggestive reference to electrolytic dissociation. Sir J. J. Thomson shows how, in accordance with his conceptions, certain molecules may combine with such polar molecules as water, to form new compounds in which the atoms of the original molecule are driven further apart. His view is that in an aqueous solution of calcium chloride the positively electrified part of the calcium atom will have next to it the negative ends of polar water molecules the other ends of which would adjoin an oppositely charged chlorine atom, the direct attraction between the calcium and the chlorine being thus diminished but not, so your reviewer reads the argument, extinguished. It is not quite clear whether Sir J. J. Thomson has not framed an explanation which would harmonise the views on solution of Prof. Armstrong and of Prof. Findlay. If so, this is a remarkable achievement. The fourth lecture is on the mechanism of chemical combination; it gives an electrical explanation of the catalytic action of platinum black, an account of the production of ions when air bubbles through water, an explanation of the work of Baker and of Dixon on dry gases, of cataphoresis, of the combustion of cyanogen in dry oxygen, of enolic change, of the luminosity of the glow worm, of varying valency, of the paramagnetism of oxygen and a few other points. This chapter alone contains enough matter to provide a reader with thoughts for several periods of leisure. The fifth lecture is on the structure of solids, not merely the structure of crystals, but surface tension at solid surfaces, intermetallic compounds, and mixed crystals.

All this is contained in a handy book of a hundred and forty-four pages of good print, and written by Sir J. J. Thomson.

OFFICIAL TRADE INTELLIGENCE

(From the Board of Trade Journal for Oct. 25)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Algeria	Iron and steel, laundry soap	458, 459
Australia	Heavy chemicals	412/7/1/1/ 167*
”	China, cut glass	412/7/1/1/ 160*
British India	Galvanised corrugated mild steel sheets	**
Chile	Earthenware	467
Cyprus	Paint, varnish, ironmongery, hollow-ware	444
Egypt	Paper (tender)	11642/F.E./ M.C.
Germany	Rubber goods, oils	451
Guatemala	Druggists' sundries	468
Latvia	Wrought iron tubes	852/10/F.G/ E.C./2
New Zealand	Olive-oil soap, olive oil	445
” ”	Builders' hardware	†
Norway	Lubricating oil and grease, rubber	453
Rumania	Zinc sheets (tender)	11706/F.E./ E.C./2
South Africa	Asphalt, galvanised corrugated iron	447, 448
Spain	Chemicals, enamel ware	454, 455
Switzerland	Dyes	457
United States	ides, skins, chamois leather	461, 462

* The Official Secretary, Commercial Branch, Australia House, Strand, London, W.C. 2.

** The Director-General, India Store Department, Belvedere Road, Lambeth, S.E. 1.

† P.O.3, c/o High Commissioner for New Zealand, New Zealand Government Offices, 415, Strand, London.

TARIFF CUSTOMS EXCISE.

Australia.—Steel, hyposulphite of soda, Portland cement, calcium carbide, salicylic acid, scientific instruments, aneroid and mercury barometers, have been brought under the operation of the Industries Preservation Act.

Colombia.—An import duty has been levied on salt.

Italy.—The present issue contains a note of the import duties on certain essential oils.

Paraguay.—Importation of pharmaceutical specialities has been prohibited.

Poland.—Increases have been made in the duties on lubricating oil, asphalt, tar, and paraffin wax.

Rumania.—New rates of export duty have been levied on gypsum and glassware.

Spain.—Regulations have been issued controlling the importation of pharmaceutical specialities.

COMPANY NEWS

BRITISH CELLULOSE AND CHEMICAL MANUFACTURING COMPANY, LTD.

The chairman, in addressing the fourth ordinary general meeting, said that the loss actually due to trading was no worse than had been expected. During the twenty months covered by the accounts the processes of manufacture in almost every direction were undergoing changes, with the object of improving the quality and cheapening the cost, of the material. Intensive efforts had resulted in the making each month of sufficient profits to cover all charges, including debenture interest, but not depreciation. Some loss had been incurred in the depreciation in value of various forms of stock, which arose chiefly through improvements which had cheapened production. The erection of a power house to meet war requirements had created a loss which was now covered, the figure being £114,000. Additional capital had been secured from the Cellulose Holdings and Investment Co., Ltd., who agreed to take up a further £400,000 of debentures. With this sum the extension of the numerous manufacturing departments had been completed, so that a production of 4½ to 8 tons per day, according to the varieties of the yarn required by the trade, was possible. Weaving plant of various kinds was also under installation, and a specialist in Lyons had already produced with celanese over 100 different fabrics. Much had been done with regard to dyeing, and the technical advisers of the company believe that they can produce any colour, shade, or standard degree of fastness, as required.

In referring to the future outlook, little doubt was felt in the company's ability to make profits under reasonable trading conditions.

ENGLISH BEET SUGAR CORPORATION

In addressing the Seventh Annual General Meeting, held on October 23, the chairman of the Corporation mentioned the assistance rendered by the Government in the remission of excise duty on home-grown sugar. The climate and soil of these islands were eminently suitable for the cultivation of first-class sugar beet, and if carefully fostered, this new industry could not fail to be beneficial to the country generally and to lead to the revival of agricultural prosperity. The cost of home-grown sugar was no greater than that of imported sugar, and its quality was, he said, better than most grades of the imported article; imports into the United Kingdom amounted, on an average, to about 1,800,000 tons annually. The home-production of even one-fourth of this tonnage, involving as it would the erection, equipment, and working of fifty factories, would be of enormous advantage to the country from the commercial point of view. It is the practice of the Corporation to issue each year with the grower's contract general recommendations in regard to beet cultivation, and this co-operation with the grower had resulted in the production in the Eastern Counties of roots above 18 per cent. sugar content. Further payment was made on a sliding scale, according to the sugar content. If the industry was to achieve success, the Government must continue its assistance until the industry is firmly established, and the British sugar beet manufacturers must avail themselves of foreign technical assistance until British technicians have thoroughly mastered the various processes of beet sugar cultivation. Progress in this direction had been made in the Cantley factory, for whereas in the early days 200 foreign operatives were brought over for each campaign, only ten were now needed. The proposal to amalgamate with Home Grown Sugar, Ltd., the owners of the Kelham sugar factory, was still under consideration.

The net profit for the year was £103,981, and after deducting this amount from the previous accumulated losses of £118,940, there remained a debit of £14,958. It was hoped this may be settled during the current year, and to reduce, if not extinguish, the £20,952 which stands in the balance sheet under the heading of maintenance account, administration and interest charges to March 31, 1920. It was not possible to pay any dividend on the Ordinary shares for last year; neither was a dividend on the Cumulative Preference shares recommended. The debenture holders, however, would receive an additional 2½ per cent. under the terms of the debenture trust deed.

The total capital amounted to £233,900, which, however, did not represent anything like the amount of money actually sunk in the business. To date £675,000 had been expended, and a modern factory like that at Cantley could not be erected for less than £460,000. The report and accounts for the year were adopted.

REPORT

Report on the Commercial, Industrial, and Financial Conditions in Japan, 1922 and up to June 30, 1923. *By* Sir, E. T. F. Crowe, C.M.G., *H.M. Commercial Counsellor, and* H. A. F. Horne, *H.M. Commercial Secretary, Tokyo. Department of Overseas Trade. Pp.* 64. *H.M. Stationery Office.* 1923. *Price* 2*s.*

The tendency so noticeable in recent years (*cf.* J., 1922, 539 R) for the Japanese to assimilate western customs becomes more and more marked. In general there is now hardly any article which would be marketable in Europe which does not find a demand in Japan. This is very noticeable in the case of sporting goods. Trade has continued to increase and, though the profits of importing merchants are not now so great as during the war boom period and prices are lower, the actual bulk of trade in 1922 constituted a record. British trade in Japan, though maintained in textiles, did not form so high a proportion of the total as before the war, and instead of being greater than that of America, is now only half as great.

The principal agricultural product of the country is rice; in 1922 the harvest was slightly above normal. Most of the minerals of the country were produced in larger quantity in 1922 than in the previous year. Among the items were gold, 100,071 oz. troy; platinum, 62 oz. troy; silver, 1,642,031 oz. troy; copper, 54,550 metric t.; lead, 3265 t.; tin, 289 t.; sulphur, 34,642 t.; sulphur ore, 42,089 t.; chromite, manganese, arsenic, phosphorus and other ores are also obtained.

Imports into the country have shown a tendency to increase, though towards the end of 1922 there was a slight decrease in imports and an increase in exports. The principal import is raw cotton. The big boom in construction materials showed some abatement, though many fine buildings were erected in the large towns. The fertiliser trade showed signs of recovery from the 1921 slump; 52,000 t. of sodium nitrate were imported in 1922. Three of the largest phosphate companies have amalgamated. The rather dull conditions in the petroleum industry continued, though hopes were entertained of cheap oil from America leading to increased use of the fuel. Trade in chemicals and drugs decreased heavily, largely owing to the practical disappearance of imports of cocaine and opium. Soda ash and caustic soda formed the principal business in heavy chemicals, 130,000 t. being imported; the United Kingdom has recovered some of this trade, though American and African competition is keen. Shellac was intensively imported to supply the gramophone record and aeroplane industries. Germany has practically recaptured the monopoly of imports of dyestuffs, over 90 per cent. of the total of 10,000,000 lb. coming from this source.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No material changes have taken place in the heavy chemical market either in demand or prices. Considering the general state of trade chemical products are in satisfactory request, although of course very considerably below what would be expected in more normal times. The home trade is steady but quiet, and the main features in export lines continue to be the "heavier" classes of alkalis.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric ..	3s. 3d. per carboy makers' works.
Acid Nitric 80° Tw. ..	£21 10s. per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali ..	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder ..	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride ..	£5 17s. 6d. per ton d/d. In slightly better demand due to weather conditions.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate ..	6¼d. per lb. d/d.
Potass. Chlorate ..	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17–£19 10s. per ton, according to quality. Prices reduced by £2 per ton.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.

Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Business in this section is generally on the dull side.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb. Reduced 1s. per lb. following drop in metal.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

The general outlook of the wood distillation industry is encouraging.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Demand steady.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade and locality of market.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d. per gall. 60% O.P. Steady market.
Solvent	6s. 3d. per gall. 40% O.P. Steady.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£41 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Fair inquiry. Good business for prompt delivery.
Crude 60's	3s. 6d.—3s. 8d. per gall. Market steady.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Firm, with a fair amount of business.
Acid Cresylic	
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 6d.—2s. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—10d. per gall. Plenty of enquiries.
Unstrained	8½d. per gall.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 6d.—1s. 7d. per gall. Little business passing.
Pure	1s. 9d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Good business being done.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d.—1s. 3d. per gall. Market sluggish.
Solvent 90/190	1s. 2d.—1s. 3½d. per gall. Very little business.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Demand increasing.
Whizzed or hot pressed	£9 10s.—£11 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	132s. 6d.—140s. per ton, according to district and time of delivery. Several inquiries. Market firm and price tending to advance.
Pyridine—90/140	22s.—22s. 6d. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Dyestuffs business has been steady during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Quieter.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—10d. per lb. naked at works.
Aniline Salts	9½d.—10d. per lb. naked at works.

Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Better demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d.—1s. 3d. per lb. naked at works.
Dinitrochlorbenzol	£85 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	6d.—7½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
Toluidine	4s. 6d. per lb. d/d.
-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The shortage of spot supplies is beginning to be felt seriously and prices are in consequence considerably higher for a few of the pharmaceutical chemicals which are in regular demand.

Acid, Acetic 80% B.P.	£47 10s. per ton.
Acid, Acetyl Salicylic	3s. 3d.—3s. 8d. per lb. Large export orders.
Acid, Benzoic	2s. 9d. per lb. Higher prices paid for good B.P. quality, which is scarce.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 4½d. per lb., less 5%, for ton lots. Poor demand.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	5s. 9d.—6s. per lb.
Acid, Salicylic	2s. 6d. per lb.—with 2s. 3d. for ton lots. Firm market. Prices advancing.
Acid, Tannic	3s. 3d. per lb. for B.P. quality.
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Home trade poor. A good demand is reported from Japanese market, but little business has been done with English acid.
Amidol	9s. per lb. d/d.
Acetanilide	2s. per lb. being asked for spot supplies. Market firmer.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	3s. 6d. per lb. for English make.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Demand very poor.
Barbitone	17s. per lb. Neglected.
Benzonaphthol	4s. 9d. per lb.
Bismuth Salts	A steady market. Carbonate 13s., Nitrate 6s. 11d., Salicylate 10s. 5d., Subgallate 9s. 6d., Citrate 11s. 7d., Oxide 14s. 5d., Subchloride 12s. 8d., Subnitrate 11s.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	7d. per lb. Considerably firmer.
Ammonium	8d. ,, ,,
Sodium	7½d. ,, ,,
Calcium Lactate	2s. 6d. per lb. for best English make.
Chloral Hydrate	4s. 3d. per lb. Position very firm.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	9s. per lb. Little demand.
Guaiacol Carbonate	Spot supplies exhausted. Present value would be 11s. 6d.—12s. per lb.
Hexamine	4s. per lb. Higher prices anticipated.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	Reduced by 2d. per lb. 2s. 3d. per lb. for cwt. lots. 2s. 4d. for 28 lb. lots.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£80 per ton, less 2½%.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 72s. 6d. per lb.
Methyl Salicylate	2s. 10d. per lb. for carboys. An active market.
Methyl Sulphonal	14s. 6d. per lb. No demand.
Morphine and Salts	Prices again advanced owing to dearness of opium. Alkaloid: Cryst. 14s. 8d., Precip. 14s. 5d., Acetate 11s. 6d., Hydrochlor. 11s. 6d., Sulphate 11s. 6d., Tartrate 14s. 5d. per oz.

Paraformaldehyde ..	.. 3s. 9d. per lb.
Paraldehyde ..	.. 1s. 5d. per lb.
Phenacetin ..	.. 6s. 9d. per lb. Higher in price and in strong enquiry.
Phenazone ..	.. Great activity has been shown. 8s. 3d. per lb. has been paid and some holders are quoting 8s. 9d.
Phenolphthalein	.. 7s. 6d. per lb. Very firm.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 90s. per cwt., less 2½%. Fair business passing.
Potass. Ferricyanide	.. 3s.—3s. 6d. per lb.
Potass. Iodide ..	.. 15s. 8d.—15s. 11d. per lb. Good steady market.
Potass. Permanganate ..	10d. per lb. for B.P. crystal.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 6s. per lb.
Salol	.. 4s.—4s. 6d. per lb. Very scarce.
Sod. Benzoate ..	.. 2s. 9d. per lb. Supplies on the short side.
Sod. Citrate, B.P.C. 1923	2s. per lb. for cwt. lots.
Sod. Hyposulphite—Photographic	.. £15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Potass. Tartrate (Rochelle Salt)	.. 82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate ..	.. Powder 2s. 7d.—2s. 10d. per lb., and Crystal at 2s. 9d. —3s. per lb. Firm and active.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal ..	.. 15s. per lb. In very small demand.
Thymol	.. 13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 11s. 6d. per lb.
Aubepine ..	.. 14s. ,, ,,
Amyl Acetate ..	.. 3s. ,, ,,
Amyl Butyrate ..	.. 7s. 3d. ,, ,,
Amyl Salicylate	.. 3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 6d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol ..	.. 3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d. ,, ,,
Benzaldehyde free from Chlorine ..	.. 3s. 3d. ,, ,,
Benzyl Benzoate	.. 3s. 6d. ,, ,,
Cinnamic Aldehyde Natural ..	.. 20s. ,, ,,
Coumarin ..	.. 20s. ,, ,,
Citronellol ..	.. 19s. 6d. ,, ,,
Citral	.. 9s. 6d. ,, ,,
Ethyl Cinnamate	.. 10s. ,, ,,
Ethyl Phthalate	.. 3s. 9d. ,, ,,
Eugenol	.. 10s. ,, ,,
Geraniol (Palmarosa)	.. 37s. 6d. ,, ,,
Geraniol	.. 6s. 9d. to 13s. 6d. per lb.
Heliotropine ..	.. 8s. per lb.
Iso Eugenol ..	.. 15s. 9d. per lb.
Linalol ex Bois de Rose ..	18s. 6d. ,, ,,
Linalyl Acetate ..	.. 18s. 6d. ,, ,,
Methyl Anthranilate	.. 8s. 6d. ,, ,,
Methyl Benzoate	.. 6s. ,, ,,
Musk Ketone ..	.. 47s. 6d. ,, ,,
Musk Xylol ..	.. 13s. 6d. ,, ,,
Nerolin	.. 4s. ,, ,,
Phenyl Ethyl Acetate	.. 10s. ,, ,,
Phenyl Ethyl Alcohol	.. 16s. ,, ,,
Rhodinol.. ..	.. 55s. ,, ,,
Safrol	.. 2s. ,, ,,
Terpineol ..	.. 3s. ,, ,,
Vanillin	.. 22s. 6d.—23s. per lb. Firm and steady demand. Raw material dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 14s. 6d. per lb.
Anise Oil.. ..	.. 1s. 10½d. ,, ,,
Bergamot Oil ..	.. 13s. 3d. ,, ,, spot.
Bourbon Geranium Oil..	37s. ,, ,,
Camphor Oil ..	.. 80s. ,, ,,
Cananga Oil, Java	.. 9s. 6d ,, ,,
Cinnamon Oil, Leaf	.. 4¾d. per oz.
Cassia Oil 80/85%	.. 11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	.. 4s. 9d. ,, ,,
Ceylon ..	.. Very little on offer, too many parcels arriving containing spirit. These have been seized by the Customs.
Clove Oil.. ..	.. 8s. 6d. per lb.
Eucalyptus Oil 70/75% ..	2s. 9d. per lb.
Lavender Oil—French 38/40% Esters	26s. per lb.
Lemon Oil ..	.. 2s. 10d. per lb.
Lemongrass Oil ..	.. 2¾d. per oz.
Orange Oil, Sweet	.. 12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 34s. per oz.
Anatolian ..	.. 26s. per oz.
Palma Rosa Oil	.. 24s. 6d. per lb.
Peppermint Oil—	
English ..	.. 70s. per lb. Market very unsteady.
Wayne County	.. 15s. per lb. Market very unsteady.
Japanese ..	.. 12s. per lb. Market very unsteady.
Petitgrain Oil ..	.. 8s. 9d. per lb. Dearer.

TRADE NOTES

German Exports of Alizarin, 1923

The following table shows the distribution of exports of alizarin from Germany in January and February, 1923, compared with the same months of 1922:—

Destination	Jan. & Feb., 1923 Metric tons	Jan. & Feb., 1922 Metric tons
Great Britain	14·0	2·9
Italy	10·8	4·0
Netherlands	6·7	12·2
British India	81·8	128·7
Czechoslovakia	0·6	12·8
Japan	4·3	1·2
Dutch Indies	12·4	2·8
United States	25·8	7·6
Other Countries	47·1	34·1
Total	203·5	206·3

German Indigo Exports, 1923

The following table shows the exports of indigo from Germany in January and February, 1923, and in the same two months of 1922:—

Destination	Jan. & Feb., 1923 Metric tons	Jan. & Feb. 1922 Metric tons
Netherlands	87·2	35·3
Austria	13·5	36·2
Czechoslovakia	4·0	20·7
Hungary	8·9	23·8
Spain	2·3	15·8
Egypt	14·3	19·9
British India	43·0	36·7
China	1763·9	1479·9
Japan	108·8	66·1
Dutch Indies	43·0	101·3
Other Countries	64·4	53·4
Total	2148·3	1889·1

German Exports of Potash, 1923

The following table shows the exports to various countries of potash fertilisers in January and February, 1923, and in the same two months of 1922:—

Destination	Jan. & Feb., 1923 Metric tons	Jan. & Feb., 1922 Metric tons
Danzig	15·0	1060·0
Memel	904·0	580·0
Saar	95·0	270·8
Belgium	4922·5	1205·0
Denmark	725·0	—
Great Britain	939·8	2730·0
Netherlands	26048·6	2113·5
Norway	5780·0	15063·1
Austria	2035·5	2657·5
Jugoslavia	90·0	3410·0
Czechoslovakia	510·0	477·5
Hungary	105·0	4602·1
Western Poland	19885·0	365·0
Lithnania	30·0	—
Finland	—	1156·0
Sweden	6834·5	6490·0
Switzerland	90·0	520·0
United States	18642·9	45937·0
Other Countries	5278·1	525·0
Total	92930·9	89392·9

The distribution of exports of potassium chloride during the same periods was as follows:—

Destination	Jan. & Feb., 1923 Metric tons	Jan. & Feb., 1922 Metric tons
Belgium	15·0	15·5
Great Britain	701·0	3643·0
Italy	195·0	190·1
Netherlands	825·1	850·1
Austria	305·5	351·0
Czechoslovakia	156·5	2429·0
Sweden	15·0	0·1
Spain	1413·3	709·1
Ceylon	101·6	304·8
Japan	0·2	60·0
Brazil	41·3	25·6
United States	5675·3	27236·4
Other Countries	606·7	910·9
Total	10051·5	36725·6

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, NOVEMBER 9, 1923 No. 45

EDITORIAL

THE dinner of chemists on October 31 was a great success; all seem to have enjoyed it: some because it was a good dinner, some because they sat near bright and chatty people, some because they enjoyed the music, some because they liked the speeches, some for all these reasons. There is something stately about a large banquet, the idle gossip before the various presidents arrive, the greeting of friends whom we have not seen for some months. "But, hark! the portals sound and pacing forth with solemn steps and slow, high potentates and dames of royal birth and mitred fathers, in long orders go." The only mitred father we had was the Vice-Chancellor of the University of Cambridge, whose amusing anecdotes were really too frivolous for a dignatory of the Church, so some of the audience said. For our part we agree with the saying that a man who is good enough to go to heaven is good enough to be a clergyman, and there is surely something charitable about a Vice-Chancellor who can be merry after a speech in which perhaps the merits and demerits of a University education have been indicated with but scant gilding of the pill. As for the feast itself, we found a table richly spread in regal mode, with dishes piled and meats of noblest sort and savour; beasts of chase or fowl or game in pastry built, or from the spit or boiled; after such meats and the appropriate fluids, we listened to speeches, some of which definitely and some of which vaguely indicated the co-operation amongst chemists, which is necessary and therefore will be accomplished. During the last two years there has been a considerable though quiet effort towards co-operation. The publication of a weekly journal by the Society of Chemical Industry was the first essential step, and the Chemical Society has encouraged this venture in a notable manner, especially by the publication in it of summaries of the papers read before the Chemical Society.

* * *

We are gratified to announce that the Institution of Chemical Engineers also has given us its encouragement and assistance. We are appointed as their official organ to publish a number of their papers in full, to furnish their Fellows with advance proofs, and to supply to such of their Fellows who are not members of the Society of Chemical Industry copies of *Chemistry and Industry*. The conclusion of this treaty, combined with the arrangement with the Chemical Society for a joint system of abstracts, involves certain changes in the details of publication. In view of the altered circumstances a complete revision of the plans of the Society of Chemical Industry becomes necessary, and those who control its destinies must rapidly decide on a number of points so that effect may be given to them at the commencement of the New Year. The support of the Institution of Chemical Engineers will give us what we have so far lacked and deplored, the latest and most authoritative information on this great branch of knowledge essential to industrial chemists. We trust with the assistance of some of the chemical engineers to publish at the end of this month the first of a series of articles dealing with this department of the science. Nor can we remain content with the successes in co-operation already announced; there are other bodies who may find that the Society of Chemical Industry and this Journal may be able in the future to afford some assistance without interfering with that independence of thought which each society so highly and so rightly values.

* * *

It is beginning abundantly to be recognised that there is an urgent need for co-operation among chemists, whether for economy, or to prevent undue duplication. But the ultimate aim of such co-operation must be, if not to make the name of the chemist a power in the land, at least to make his work understood and respected. The builder of bridges or railways and the man who works in the machine shop are both known as engineers to the public, yet their respective functions are, we imagine, but rarely confused. It is true that there is something spectacular about engineering that appeals to the lay mind, whereas the chemist's work is more subtle, not so immediately obvious, but there is no reason why the amazing powers of chemistry should not be appreciated more fully. The suggestion has been made to us that the present lack of understanding is due to the chemist himself, and that he should emerge from his laboratory or lecture room and consort with all manner of men, carrying with him the chemical point of view into council rooms, local associations, or any other forms of public service. Such a course would undoubtedly strengthen the position of the individual, and this again would react on the strength of the mass. The pace of an army is that of its weakest unit, and this applies none the less truly to the chemical profession. If each chemist occupied his proper place as a citizen, he would act as a catalyst and stimulate the whole of public opinion, so that chemistry could not but occupy a greater place in the general esteem. Then would the attainment of our ideals be greatly facilitated, for as the action of the unit became more effective, so would that of the whole body chemical. We are told that, in the United States, chemists are frequently to be found serving with distinction in public offices, and chemistry in that great country does not altogether lack public appreciation. Let us draw the moral and apply it.

* * *

Lord Exmouth has testified his belief in the value of Chemical Clubs both in America and in Great Britain. The Chemists' Club in New York and the Chemical Industry Club in London have both been conspicuous successes, not only as clubs, but as a means of bringing together the many interests of the science and the industry. The Club in London owes its formation and its success very largely to the enthusiasm and good sense of Mr. H. E. Coley, who to the regret of all has found that he is unable to spare the large amount of time he has hitherto devoted to his congenial task of Honorary Secretary. It is in great measure due to his tact, his sociability and his determination that chemists naturally go to the Club whenever they can spare the time, knowing that they can be sure of finding there some men whom they know and are glad to meet. He has in this way rendered a valuable service to the chemical world, and the best way we have of showing our gratitude to him is to encourage in every way the institution in which he has so just and worthy a pride. Not that this is the only or even the main reason for such encouragement, there are more cogent ones; the dining-room, the smoke-room and even the billiard-room in Whitehall Court have enabled us all, whether we are chemists or merely those who live in a chemical atmosphere, to know ourselves and our associates better. Conscious as we are of each others infirmities—as the Committee is stated to have begun its report—we shall more easily and quickly make progress.

DINNER OF CHEMISTS

The dinner arranged under the joint auspices of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry was held at the Edward VII Rooms of the Hotel Victoria, London, on October 31. Sir William Pope, K.B.E., F.R.S., was in the chair and there was a company of 198, including many ladies.

After the usual loyal toasts, Lord Wargrave, P.C., proposed the toast of "Chemistry and the Nation," and coupled with it the name of Sir William Pope. The science of chemistry, he said, had done most remarkable things. At the outbreak of the war tremendous leeway had to be made up in the chemical industry and in chemical research, because previously we had been willing to depend upon the foreigner and, more curious than all, upon our chief antagonist in the war, for many essential chemicals. The chemists of this country were able to produce all that was required for the conduct of the war, and the position which the chemists were able to achieve in wartime—if we were going to be true to ourselves and to our countrymen—we were determined to maintain in peace time. Surely with all the present unemployment and the necessity for keeping up our industries it would be crass folly for us to allow those industries to be dependent upon foreign production. He sincerely hoped that the great experience which had been gained by chemical manufacturers during the war was not going to be lost, but that we should see security was given to chemical industry to enable chemists further to develop the discoveries which they made during the war period.

Sir William Pope, replying to the toast, said that those who had listened to Lord Wargrave's eloquent speech would realise that outside purely chemical circles there were enlightened people who appreciated and understood how much chemistry means to the nation. During the war we heard a great deal of the importance of chemistry to the nation. Even after the Armistice, we heard echoes of this, but he was afraid that appreciation of the importance of chemistry to the nation was becoming more and more feeble and that we are dropping back into the old way of letting things run on and trusting to luck that they would right themselves at the proper moment. But chemistry at present was not quite so much on the horizon as it was before; it may even have gone below the horizon a little, and it was the duty of public men like Lord Wargrave, just as much as it was the duty of chemists themselves, to see that this state of affairs was not perpetuated. It seemed to him that the main function of a gathering of this nature, at which chemists belonging to many sections of the chemical community were gathered together, was for them to take counsel together and to discuss what can be done in the future in order to push the interests—first of their own special subject, chemistry, and secondly the interests of the nation with respect to its concern with science generally. He hoped that a function of this sort would be held at quite frequent intervals so that they could consider what had to be done.

Mr. W. J. U. Woolcock, C.B.E., proposing "Our Chemical Organisations," coupled with it the name of Prof. W. P. Wynne, F.R.S., president of the Chemical Society, and said that chemical science and technology in this country was very well served with Associations. One thought, of course, immediately of the Chemical Society going back to 1841, with some 4000 or 5000 members; one also thought of the Institute of Chemistry, also founded before he was born, having fellows and students and so forth of well over 5000, and there was the Society of Chemical Industry with a membership of over 5000. There were all these big general societies, and there were also a number of special societies and associations. There were many societies—he hoped nobody would say too many—but he was not quite sure whether some of these societies might not be able, in the interests of economy of effort and of efficiency, to find some form of combination, some form, perhaps, even of loose linking up, which would enable them to work in much closer touch with the more general societies to which he had referred. (Applause.) A considerable amount of co-operation and linking up had taken place. The presence of Dr. Herty reminded him that recently the American Chemical Society and our own Chemical Society had arranged to co-operate in producing the *Journal of Physical Chemistry*, which was all to the good; a sign of the times. After all, what was this dinner? It was a dinner of the chemical Allies and the toast he was proposing was the toast of the chemical Allies. They might not yet put it in that form. We were typically British whatever else we were, and we did not propose to do anything in a hurry. Therefore, at this first joint meeting the toast was discreetly put down not as the toast of the chemical Allies, but as the toast of "Our Chemical Organisations." If to-day was the day of anything, it was the day of co-operation and co-operative effort. Everybody in every sphere of life was trying to see whether any economy could be effected by working together; whether there was any increased efficiency to be gained by such effort; and to-day the members of chemical organisations of various kinds had met together to see what were the possibilities in that direction. There was one body to which he wished specially to refer and that was the body presided over by Sir William Pope, the Federal Council. He supposed everybody present had watched the Federal Council and its formation very closely indeed. He did not, himself, think that it was the business of the Federal Council to act independently; he did not detect on that Council a desire to usurp the position of any of the other bodies; but he did think there was room for the Federal Council to act, perhaps in two ways. The first was that the Federal Council might quite easily be a forum, so that ideas with regard to progress among the various societies could be offered to it for consideration. There was also one thing which the Federal Council had set out to do, but had not yet accomplished, although he believed it would ultimately be accomplished, viz., the establishment of a central home for chemical organisations. Ultimately, perhaps, that would be the first great achievement of the Federal Council. He was inclined to think that there is a far greater movement taking place around us than we are conscious of in that linking up of chemical industries and the scientists who are working with them. It was rather a triumph for the Society of Chemical Industry to be able to start a weekly paper. It was rather a triumph that the Chemical Society should come in and assist in the manner they did, and also, from the industrial point of view, that the Association of British Chemical Manufacturers should also have come in. That was a mere beginning, and there was also a project for the publication jointly of scientific and technical abstracts. All these things proved that progress to-day with the societies was by no means slow.

Prof. W. P. Wynne, F.R.S., acknowledging the toast, said that without doubt the number of chemical organisations was considerable, and Mr. Woolcock had rather suggested that there were too many. Whether that be so or not, it would not be suitable that he should discuss it on this occasion. Without doubt, these associations served a very useful purpose, but when considering them it was impossible not to be struck by one fact, that only two of them possessed homes of their own. One of them was the Institute of Chemistry which had built its own house within recent times, so that it might be supposed to be ample for its purpose. The other, was the Chemical Society, which was merely a tenant in its own house, and in that house accommodation was severely restricted. The Chemical Society offered hospitality to all the other societies which were able to make use of its rooms, but the accommodation was very small. They had been told that within a year they would not be able to find room for their books in the library, which was the most important chemical library in this country. The Chemical Society had been told, on taking up this matter with the Government, that it must either try to find accommodation with the other societies in Burlington House—which themselves were severely pressed for room—or else go out into some remote part of London where rents are cheap, and find a home for themselves. That was the position which, in the opinion of certain Government departments, chemistry holds five years after the war. (Shame.) What was required at the present time—and Mr. Woolcock was doing good work in that connexion—was a campaign of publicity.

Chemists had got to explain themselves to an unbelieving country. The country did not understand the chemists or their work, and until some progress had been made in that direction he was afraid they would always be open to the difficulties to which he had referred. If, in the days to come, they succeeded in getting a home for all the chemical organisations, then, perhaps, the country would believe in chemists. Therefore, it seemed to him that they had in Mr. Woolcock a leader whom they should follow to the best of their ability. The work he was doing in connexion with the big exhibition was all to the good, and they should back him up to the best of their ability, and so hasten the day when that sun of chemistry, to which reference had been made, had arisen above the horizon and had dispelled the mists which now hide from the minds of our countrymen the supreme importance of chemistry to a nation like this, which depends upon its industries for its very existence.

Dr. E. F. Armstrong, F.R.S., President of the Society of Chemical Industry, in proposing "The Universities," and coupling with it the name of the Rev. E. C. Pearce, the vice-chancellor of the University of Cambridge, said he supposed he had been selected to propose this toast because he was in part a renegade. Having been trained in connexion with Universities he had deserted and had gone over to industry—he spoke now as a representative of industry, as a convert to industry, and as a believer in industry. It was our habit to attribute unemployment to every cause under the sun; the war, the inefficiency of our politicians, and particularly to the gross incapacity of those who led our industries and our chemical industries in particular. The text he was going to preach from, however, was faith. There was a very great man in this world once, not an Englishman, but an American representative, Robert E. Lee, to whom there came, perhaps the greatest choice of all, the choice between his honour as a soldier and his love for his country, and he, just as a simple gentleman would, chose his country. Perhaps they would remember the words of his choice. The words were, "Argument is over; faith begins"; a very honourable sentiment. To-day they were holding a joint meeting of a number of the chemical societies; they had noble ideas, but they had a feeling of grievance that they had been left in the rut. They got up and talked and blamed everybody excepting themselves, but what he wanted to suggest was that they should have more faith in themselves, and in those whom they chose as their leaders if they were going to deserve success. If they did not deserve success then they would never achieve it. Faith was what they must have. Unfortunately the whole education of the chemist was that he was brought up to analyse, to criticise and to argue, and he never lost those horrible habits. As chemists they must cast this trait out of their characters if they were to work together and achieve great things. They must not criticise, they must not analyse; they must have faith. A profession that was critical, carping and niggardly and had any faults of that description could not hope to attract into its ranks big open-hearted men such as the English nation had been only too proud to possess.

The Rev. E. C. Pearce said that he agreed with Dr. Armstrong that what is wanted is not only a trained chemist, but a man with vision. He himself had always thought that the great advantage of the older universities was that they produced not mere machines, but men who could be entrusted with a job and who knew what to do when they were in a tight fix. Personally, he believed the older universities were able to produce men with the technical knowledge and also with this power of vision and decision, and although he did not want to blow the trumpet of Cambridge too loudly he must say that there is no chemical school in the country at the present time which was better housed or better staffed than that over which Sir William Pope now presided.

Lord Exmouth, who received a cordial welcome, said he had gone to America when a boy of nine, and went to the School of Mines at Colombia University. In his third year he came to Europe to study some special aspect and on his way to England stopped at a man's house. During an after-dinner discussion, he was told that to have given up the classics to study science was an absolute degradation, and when later he said he intended to study chemistry, his host was horrified, and seemed to think that he would be rolling pills all his life in an apothecary's store. He impressed upon those people, however, even then his belief that the country which had the most chemists and the best chemists would be the one that would win out in the future. Manufacturers generally were now beginning to appreciate the importance of having a first-class chemist in their works. This was the case to some extent in America, but it was not done to the extent it ought to be. At the same time, all the great firms had their laboratories, and industry in America to-day was based very largely on chemistry. Something had been said during the evening about co-operation of the different chemical societies and of the manufacturers. In America the greatest possible advantage from this point of view had been obtained from the Chemists' Club. At this club meetings were held at which chemists and all those interested in chemists were welcomed, not only from New York, but from all over the country. It was for this reason that he had been interested to find in London a Chemical Industry Club of which, thanks to Sir William Pope, he had been elected a member. He concluded by expressing the hope that the Chemical Industry Club in London would grow into one of the great central organisations of the world for chemists.

THE BOHR ATOM

By Dr. J. D. MAIN SMITH

The extension of the frontiers of scientific knowledge into domains, regarded a very few years ago as unknowable or remote from any possibility of experimental demonstration, has perhaps been nowhere so great or so rapid as in the sciences overlapping the borders of chemistry, which to-day merges indistinguishably into the newer profundities of physics and mathematics, to an extent almost inconceivable even a decade ago. The atom, which had been for nearly a century merely a hypothetical primary particle of chemistry, is now known with certainty not merely to have reality, but to have detailed structure, and to consist of small particles, electrons, of almost inconsiderable mass, and a yet smaller central nucleus, possessing almost the whole mass of the atom. The electrons in the neutral atom are further known to carry equal negative electric charges, the nucleus carrying a positive electric charge equal to the sum of the electronic charges.

As no components of atoms are discernible, other than electrons, nuclei, and electric charges, it can hardly be doubted that in this grained and electric structure lies the cause of the difference in the physical and chemical properties of the elements, and much research has been devoted to the elucidation of the possible, probable, and actual nature of the atomic structural arrangements and governing forces. The probing has been so deep and the results so extensive and suggestive, that direct application to the experimental facts of chemistry has become possible, and several theories, based on electronic structural systems and claiming to give a more or less adequate interpretation of the broad outlines and fundamental principles of chemistry, have been propounded within the last few years.

The accumulation in chemistry, however, of a vast detail of exact and abstruse knowledge, has made the average chemist necessarily a specialist, not merely in one science, but even in one small section of a science, and he can seldom keep abreast of the advances in real knowledge in his own science, much less in the overlapping sciences. The multiplicity of these atomic theories is, consequently, an embarrassment, and renders it difficult to come to a decision as to which, if any, of the theories can usefully be applied to the practical and theoretical problems of chemistry. Instinctively, and perhaps properly, the chemist tends to be sceptical of the validity of chemical conclusions drawn from purely physical and mathematical considerations, and such conclusions are seldom accepted until they have been examined by chemists generally, and demonstrated to accord with the established chemical facts and principles.

Of the various atomic theories that have been put forward, only two can be said to have survived critical examination by chemists. These two theories are associated with the names of Langmuir and Bohr, respectively, and, though similar in regard to the division of the atom into numerically fixed groups of electrons round a central nucleus, differ fundamentally as to both dynamics and derivation. The Langmuir theory, which extends the earlier theories of Thomson and of Lewis, interprets the general and periodic properties of the elements in terms based on a series of postulates, formulated solely for the purpose of the interpretation, and assumes that the electrons of an atom are fixed in more or less static configurations, in small areas of concentric shells of electrons with the nucleus as centre. The Bohr theory, on the other hand, explains the specific properties of elements in terms based on an interpretation of the optical and X-ray spectra of elements, assumed as originating in electrons, possessing *kinetic* energy in virtue of their revolution around the nucleus according to definite mathematical and dynamic laws. The Langmuir theory has enjoyed almost a vogue in many chemical circles, despite that its application to chemistry requires special assumptions for nearly every element and for many classes of compounds, and is definitely irreconcilable in many cases with the chemical evidence. Bohr and others have further pointed out that, if the only forces within the atom are due, as the evidence indicates, solely to electric charges, then a static configuration of the electrons is impossible. It therefore appears that the Langmuir theory, however chemically attractive a static theory may be, has no sound foundation, and its title to application to chemistry must be held to be dubious.

In his "Theory of Spectra and Atomic Constitution," 1922, page 93, Bohr states: "My main purpose will therefore be to consider the fitness which the configuration of the electrons in the various atoms offer for the formation of *ions*." It is not therefore to be expected that the theory can offer any adequate explanation, in its present form, of the vastly more difficult problems of organic and co-ordination chemistry, relating entirely to complex compounds in which the atoms are non-ionisable. Dr. Sidgwick has, however, in papers read recently before the Chemical Society and the British Association (*J.C.S.*, 1923, **123**, 725, and this vol., page 901), elaborated an extension of Bohr's theory to the electronic constitution of the atoms in co-ordination compounds, by utilising part of Langmuir's theory. This extension will be dealt with later, and it is proposed firstly to examine in some detail the application of Bohr's theory to some of the simpler experimental facts of chemistry, for if it be incapable of interpreting the simpler facts, its claim to apply to more difficult problems must be discounted.

Restricting, for a moment, the application of the Bohr theory to matters of ionisation, to which it mainly relates, it is remarkable that, though full provision is made for the existence of atomic ions carrying one positive charge, and two, three, and four positive charges, no cognisance appears to be taken of the much more important fact that no atomic ions are capable of existence carrying more than one *negative* charge. Further, the phenomena of oxidation and reduction, the basis of the whole chemical theory of valency, are explained by Bohr as very simple matters of gain or loss of electrons by ions. When, however, it is realised that the great bulk of these phenomena relates to atoms incapable of furnishing ions and to compounds in which the atoms are non-ionisable, it is obvious that the field of the actual application of the electron valency theory is thereby restricted to dimensions quite inconsiderable in chemistry. Moreover, it is practically certain that the ions of all bi-, ter-, quadri- and quinque-valent elements, and some univalent elements, are not simple atomic ions, but complexes of metal and solvent molecules. No account is taken of this almost universal hydrolysis (ammonolysis, etc.) of simple salts to form non-ionised basic salts, non-ionised hydroxides, or complex salts having non-ionisable components, and the theory is therefore applied in misapprehension of the facts.

No provision is made for the fact that boron has practically no basic properties, unlike its congeners aluminium, scandium, etc., and that, though a tervalent non-metal, it is incapable of forming any compounds with the contra-valency of five, unlike nitrogen, also a tervalent non-metal, which readily exerts the contra-valency of five. When account is taken of the extremely symmetrical structure assigned to carbon to account for its physical inertness and its chemical idiosyncrasies, no explanation seems possible of the existence of carbon monoxide, the difficulty attending its decomposition, and its feeble additive properties. Considering that nitrogen is assigned a structure in which one electron appears in a 2_2-quanta orbit, and more feebly bound than the other four electrons in 2_1-quanta orbits, it is difficult to understand why this single electron should not be readily available and nitrogen thus be definitely univalent. It is impossible to claim that nitrous oxide contains univalent nitrogen. Its formation from NH_4NO_3 is precisely analogous to the formation of azoxy-compounds in the reaction between aromatic amines and nitro-compounds, in which the product has the structure  $Ar{-}N{=}N\begin{smallmatrix}\nearrow O\\ \searrow Ar\end{smallmatrix}$ nitrous oxide therefore having the structure $N{\equiv}N{=}O$. It is similarly difficult to understand why nitric oxide, NO, and nitrogen peroxide, NO_2, exist. No provision is made for the inability of nitrogen to combine with fluorine, in view of the existence of chlorides and iodides of nitrogen, nor for the existence of NO_2F, and non-existence of NOF_3. There appears to be no reason why oxides of fluorine and bromine should not exist, in view of the existence of oxides of chlorine and iodine, nor why chlorine should not combine with fluorine or bromine, in view of the fact that oxygen combines readily with all the members of the family to which it belongs.

Though both thallium and indium in the third periodic group have univalency, neither boron nor aluminium is ever univalent. This is the less understandable in view of Bohr's admission that, on the spectral evidence of sodium, magnesium and aluminium, the latter has the 13th electron in a 3_2-quanta orbit, despite that only two instead of the four required tetrahedrally arranged electrons can be in 3_1-quanta orbits. If all three electrons are in 3_2 orbits, they will be less firmly bound than in 3_1 orbits, and aluminium be a stronger base than magnesium, which is untrue. If only one electron is in a 3_2 orbit, aluminium should be definitely univalent, which is also untrue. Many inferences are possible: that 3_2 orbits do not correspond to a feebler binding than those of 3_1, that the more feebly bound electrons are not the last built into the atom, that two of the valency electrons of aluminium are neither in 3_1 nor 3_2 orbits, or that the spectral evidence is wrongly interpreted. Each of these inferences vitiates Bohr's general theory, yet no other is possible. Overriding the difficulty, Bohr goes on to assume that the valency electrons of silicon are in 3_1 orbits, and similar in configuration to the 2_1 electrons of carbon. This arrangement leaves no loophole to account for the fundamental difference between carbon and silicon, in that quadrivalent carbon atoms have their chemical affinity completely satisfied, whereas quadrivalent silicon atoms are still capable of further chemical combination. SiF_4 combines with two ammonia molecules, to form $Si(NH_3)_2F_4$, and with two fluoride ions to form the complex ion SiF_6, whilst $SiCl_4$ combines with six ammonia molecules to form $Si(NH_3)_6Cl_4$.

Similar examples of the inadequacy of the Bohr theory to explain the structure or the existence of simple compounds or to account for the chemical activity of elements, could be multiplied almost indefinitely, despite the provision in the theory of vague and complicated suggestions (hardly schemes) to account for the three sets of transition elements and their neighbours in the periodic classification, and for the family of the "rare earths." The theory must be held to be incapable of general application in chemistry, but, undoubtedly, it is applicable to all cases of simple atomic ions, and throws much light on the probable structure of atoms both in the elementary and combined states, on the probable cause of their reactivity, and on the stability of their compounds. The fact that it is based largely on the chemical facts summarised in the periodic classification, on the experimental facts of spectrum analysis, and on mathematical and dynamic laws, encourages the belief that the Bohr atom is largely a reality, and an admissible chemical expedient.

In Dr. Sidgwick's extension of the Bohr theory to co-ordination compounds, a relationship is developed between atomic structures and the co-ordination numbers of Werner's theory. The postulates required by this relationship have no mathematical or dynamic necessity consequent on the electronic configurations of the suggested Bohr atoms, but are extraneous assumptions arising from the absence in Bohr's theory of any provision for combination between atoms without ionisation. They relate, consequently, to the electronic links between non-ionisable atoms and to the distribution of the electrons in the atomic structures. In how far these postulates are derivable from provisions in Bohr's theory or are in partial or complete disagreement with certain features of this theory, which they are claimed to extend, will be indicated later, but it may be stated here that they scarcely furnish a sufficient basis on which a consistent explanation of chemical problems can be built.

The first postulate concerns atomic linking, and is identical with that originally formulated by Lewis, and largely utilised by Langmuir in his elaboration of Lewis's theory. It is that *two* electrons are necessary in the junction between non-ionisable atoms for every chemical valence, the electrons being simultaneously portions of both atomic structures. With regard to this linking, known as a co-valency, Dr. Sidgwick states: "How this sharing of electrons is effected is still uncertain. Each electron certainly forms part of the constitution of both the atoms which it joins." It might be supposed from this that the existence of co-valencies was a proven fact. Actually there is no evidence to support it. The necessities of an applied scheme of co-valency makes it plausible, particularly in the realm of organic chemistry, but in inorganic chemistry the postulate of only one shared electron is probably as useful, and would certainly appear to be a more logical extension of Bohr's theory. It is certain that chemical valency is measurable in all classes of compounds, whether or not ionisable, in identical terms, oxidation or reduction equivalents, and is identified in Bohr's theory with singly transferred electrons. It yet remains to be proved that there is any fundamental difference in the nature of the essential reaction of atoms, to produce ionisable and non-ionisable compounds. Take the case of the typically co-ordinated compounds, the silicofluorides, in which the fluorine atoms are somehow bound to the silicon atom, so that the SiF_6 radicle reacts as a complex ion. With barium salts, simple double-decomposition occurs, and $BaSiF_6$ is quantitatively precipitated. With calcium salts, particularly if an excess be used, CaF_2 and silicic acid are almost instantly precipitated, the fluorine atoms being evidently almost as readily available as in an ordinary ionic double-decomposition with a simple fluoride, such as NaF. On this fact, indeed, are founded the two most reliable methods for the estimation of fluorine, the CaF_2 being weighed when calcium acetate is used, and the HCl liberated being titrated when $CaCl_2$ is used. If any inference relative to electrons may be drawn, it is that the electronic link between fluorine and silicon is practically indistinguishable from the electronic link between ions, such as NaF. It may further be remarked that, in the case of the metal amines, every stage between complete ionisation and complete non-ionisation of a co-ordinated atom, such as a halogen, has been experimentally realised. It is not suggested that the co-valency postulate does not represent a reality. It may be the real bond in all chemical reactions involving non-ionisable atoms, but it is not a necessary conception for inorganic chemistry. An exhaustive application of the conception of *one* electron per bond to all classes of chemical compounds breaks down only in the case of straight chains of atoms containing more than three *carbon* atoms, *i.e.*, only on entering the realm of undoubted aliphatic and aromatic chemistry.

The second postulate concerns the number of co-valencies (or non-polar links) that can be associated with an atom. It is that the maximum number of co-valencies is equal to twice the principal quantum number of the group to which the valency electrons are assigned in the Bohr atom. This number is further identified with the number of electrons in the sub-group to which the valency electrons belong, and with the maximum co-ordination number. The last two identifications do not accord with the facts. From Na to Cl, the valency electrons are in sub-groups having the principal quantum number 3; nevertheless, the completed Bohr atom has only 4 electrons in each of two of three possible sub-groups. Twice 3 is not 4, even in the Bohr atom. The majority of the elements from atomic number 29, Cu, to 92, U, deviate similarly from this rule, owing to the fact that, though principal quantum numbers increase systematically, the number of electrons assigned by Bohr to the "outer" or valency orbits is usually 4 and occasionally 6. From what follows it will be seen that the co-ordination number, admitting even the most doubtful cases of highest number, is not equal to twice the principal quantum number for most of the elements in the periodic classification. The origin of this postulate is not difficult to see, for Bohr utilises the idea to find room for the transition elements and the rare earths, the inert gases having invariably 4 electrons in the "outer" orbits, whilst the structures of intermediate stability, Ni, Pd, and Pt, have some or all of the corresponding orbits with a number of electrons equal to twice the principal quantum number. The numbers in Bohr's groups are based on real experimental evidence, optical spectra and the periodic properties of the elements. The numbers in Dr. Sidgwick's groups have no necessity beyond a desire to obtain an inert gas structure or, failing that, any structure that looks symmetrical. The number of electrons in co-valencies, involved by the attempt to identify co-ordination number with number of co-valencies, compels the abandonment of the invariable inert gas type, and a new type is proposed, every atom having at least one such type, and some atoms several types. This lack of provision of even a few standard types cannot be regarded as a satisfactory general solution of co-ordination problems, and their multiplicity appears unnecessary. A single example will illustrate the point. The AlF_4 group contains $13+36+1=50$ electrons. If the F atoms have the neon structure of 10 electrons, 40 in all, 10 are left, which with the 8 in 4 co-valencies, make 18, the argon structure, for Al. On the other hand, the AlF_6 group contains $13+54+3=70$ electrons. If, as before, the F atoms have neon structures, 60 electrons are required, and 10 are left, which with the 12 in 6 co-valencies make 22 for Al, the atomic number not of an inert gas but of titanium, one of the most chemically reactive elements known, yet the type to which we are asked to believe the inert substance, cryolite, Na_3AlF_6, is to be referred.

It is claimed that this postulate enablse the maximum co-ordination number to be predicted. From Li to F, the principal quantum number for the valency electrons is 2, and the co-ordination number should be $2\times2=4$. Dr. Sidgwick states: "Here therefore the co-ordination number cannot exceed 4; this fact is generally admitted by the Werner school." This *fact* may be disputed, on the grounds that the Werner theory is not concerned with theoretical maximum co-ordination numbers, but with the numbers experimentally realisable, and that the number 4 is apparently frequently exceeded in this group. The number 6 for beryllium and the numbers 5 and 6 for boron are apparently possible, *e.g.*, $Gl(NH_3)_6Cl_2$, Na_2BF_5, $B(NH_3)_3F_3$, and H_3BF_6, and the hexa-borotungstates. The number 5 is known for nitrogen, the penta-alkyl derivatives having recently been isolated, and no compound is known in which a *greater* co-ordination number than 2 can be assigned to fluorine. Further, from Na to Cl the principal quantum number is 3, and the co-ordination number should be 6, which is more than doubtful for Na (4 is a probable maximum in practice), untrue for Al and Si (K_4AlF_7, K_3SiF_7, and $Al(H_2O)_{20}F_3$ are known), and for P and Cl, the known maxima for which are 5 and 4 respectively. It thus appears that 9 of the 14 valent elements from Li to Cl do not accord with the postulate.

Further, Bohr has shown that K and Ca have their valency electrons in 4_1 orbits, thus involving co-ordination numbers of 8. This may be admitted for Ca, but is certainly untrue for K, for which the number is in practice usually zero. From considerations of the arc and spark spectra of K and Ca, Bohr states that, from this point onwards to Ni, the binding of a 3_3 electron is firmer than for a 4_1 electron, and the valency electrons from Sc to Ni must be regarded as in 3-quanta orbits, and the co-ordination numbers should in consequence be 6. Nevertheless, a common co-ordination number for titanium is 7, and 8 is not infrequent, *e.g.*, TiF_7x_3, $TiO_2F_5x_3$, TiF_8x_4, $Ti(NH_3)_4F_4$, $Ti(NH_3)_6Cl_4$, and $Ti(NH_3)_8Cl_4$. It is evidently not correct to state that "the 4-quantum group begins to be filled up after we have got past nickel (28), and though a co-ordination number of 8 is rare . . . we find it as early as zirconium" (40). The facts are that the 4-quanta group is in evidence as early as potassium (19), and co-ordination numbers of 8 are by no means rare and are found as early as titanium (22) and probably as early as magnesium (12).

Bohr's theory provides for 4-quanta orbits from Cu(29) to Br(35), and from Y(39) to Pd(46), for 5-quanta orbits from Ag(47) to I(53), in Rb(37) and Sr(38), and from La(57) to Pt(78), for 6-quanta orbits in Cs(55) and Ba(56), and from Au(79) to Po(84), and for 7-quanta orbits from Ra(88) to U(92). This involves that co-ordination numbers of 8, 10, 12, and 14 should be common in chemistry. Nothing could be further from the facts, for numbers higher than 8 are decidedly rare, and, where they do occur, cannot be foretold from Dr. Sidgwick's postulate. Osmium should have a maximum of 8, but $OsCl_{12}Na_6$, and $OsCl_{12}K_6$ are both known. Columbium should also have a maximum of 8, but $CbF_{10}x_5$, and $CbF_{12}x_7$ are well known types. Uranium should have a maximum of 14, but the highest known is 11 in $UF_{11}x_8$. Tantalum should have a maximum of 10, but cases of 12 are common, and even 20 appears possible in $TaF_{20}x_{15}$. If the postulate is claimed to govern only ideal maxima it is irreconcilable with the fact that such ideal maxima are frequently much exceeded in known compounds.

A closer examination of the postulate, however, seems to indicate that it is inconsistent with the fundamental feature of Bohr's theory that every electron, having a particular quantum number, must actually execute the orbit round the nucleus, in a path determined by the principal and subsidiary quantum numbers, which limit the major and minor axes of revolution. As the electrons in co-valencies are derived from considerations of the principal quantum number of the orbits of the valency electrons, the co-valent electrons must by inference be characterised by this quantum number. In the case of the cobalt-amines an obvious discrepancy arises, for the valency electrons have quantum number 3, and the co-valency electrons therefore the same. The cobalt atom has 14 electrons in 3-quanta orbits and $3 \times 6 = 18$ is the most that can be placed in such orbits, *i.e.*, 4 more than the atom possesses. These could be supplied by 2 co-valencies, but the co-ordination number of cobalt is 6, thus involving 6 co-valencies or 12 electrons, 8 more than the orbits can accommodate. Dr. Sidgwick assigns the 8, without comment, to 4-quanta orbits, thus violating the conditions on which the postulate claims relationship with Bohr's theory. It is peculiar, though perhaps only accidental, that cobalt is used as one of Dr. Sidgwick's illustrations, and that the structure arrived at is 2, (44), (666), (44), identical with that of the inert gas krypton. Had chromium been chosen (its amines are almost indistinguishable from those of cobalt in most of their properties) no such coincidence could have occurred, nor, indeed, for almost any other element.

The new types of atomic structures, other than the inert gases, are based on what is termed " the effective atomic number," which is the " actual number of electrons, shared or not, which are attached to the atom in the particular compound. It is attained by adding to the actual atomic number one for every substitution link and two for every link where the two electrons are taken from another atom . . . and allowing for the electrons added or removed by ionisation." This number is then to be resolved " on the Bohr system " into the most probable groups and sub-groups. It is pertinent to enquire how one is to decide when a link is a substitution link and when it is some other kind, and when two electrons are to be taken from another atom. For example, in the case of the acetylacetones of zirconium, three electrons per acetylacetone residue are to be added, but can three be added for the acetylacetones of thallium and of *all* the alkali and alkaline earth metals ? If so, no explanation appears possible for their instability to hydrolytic agents and rise of temperature. If not, the rule ceases to be applicable, as the exceptions are too numerous to be disregarded. The resolution of the " effective atomic number," moreover, cannot in any event follow the " Bohr system," for groupings are frequently obtained which have no meaning in Bohr's theory. Too much stress cannot be laid on the fact that the Bohr electronic groupings are conditioned, not by what any particular person may consider the most probable groupings, but by mathematical, dynamic and chemical considerations, based in the main on real experimental evidence. The " effective atomic number " may mean anything or nothing, for the " actual number of electrons " attached to an atom is quite indeterminate at present, except perhaps for atomic ions. The resolution of such numbers into groups is, therefore, admissible only when equal to Bohr's ionic numbers, and, if not equal, the groups obtained by any process of resolution can have no necessary reality, being dependent only on personal predeliction, within the limits of the first four even numbers.

The position of the first element, hydrogen, in the extended Bohr theory, is decidedly anomalous, for the postulate necessitates that it have a maximum co-ordination number of two, or two co-valencies consisting of 4 electrons. As the quantum number for hydrogen is unity, the maximum number of electrons that can be accommodated in such quantum orbits is 2. Consequently, two of the co-valency electrons must be assigned to orbits to which their quantum number does not relate. This appears impossible, for in the Bohr atom an electron cannot have two principal quantum numbers, *i.e.*, cannot revolve in two different orbits simultaneously.

It is proposed to increase the valency of co-ordinated atoms in proportion to the number of electrons held in co-valencies. It appears to be time to raise at least a mild protest against the misuse of the fundamental chemical conception of valency, which is not merely an abstract idea, but the name for a real quantity, measurable in the ordinary terms of oxidation or reduction equivalents. NH_4Cl must contain *ter*-valent nitrogen and *uni*-valent chlorine, because, however it be synthesised, only four equivalents of hydrogen are necessary for the complete reduction of both the nitrogen and chlorine atoms from the free to the combined state, conclusive chemical evidence that the nitrogen atom cannot be *quadri-* or *quinque*-valent so long as the chlorine is accepted as *uni*-valent. Purpureo-cobalt chloride $Co(NH_3)_5Cl_3$, contains *ter*-valent cobalt, as was proved experimentally by both Gregory and Gibbs over 70 years ago. To assign to the cobalt atom a valency of 9 is to misunderstand the meaning of valency. It may have 9 electrons associated in its periphery, or any other number that any other electron theory may require, without any alteration in the chemical fact of its measurable *ter*-valency. Dr. Sidgwick and others agree in assigning to metallic atoms *negative* valency, in spite of the certain chemical knowledge that metallic atoms are oxidised, not reduced by chemical combination. This inversion of the chemical facts makes the practical application of such ideas very difficult, and does not appear to advance the solution in the slightest.

The difficulties attending the application of the co-valency postulate and the theories based on it in its present form, all appear to take their rise from idea that two shared electrons can be simultaneously effective in two atomic structures. It is doubtful if the facts or the electrons are so simple or lie so close to the surface. The mechanism is too simple to be capable of interpreting the multitudinous facts of the chemistry of non-ionisable complexes and organic compounds. It seems imperative that the shared electrons must react as if only one at a time were effective in any one quantum orbit, and provision must therefore be made in each atom for a harmonic reaction between the shared and unshared electrons bearing the same quantum number, resulting in mutual deformation of the electronic orbits, so that the continuous path of the shared electrons lies between and round the nuclei of both atoms. The fact that this problem, which is the astronomical problem of the twin-sun system, is not completely soluble by the present-day mathematics, need not necessarily be discouraging. The enormous mass of chemical facts, derived from co-ordination and organic chemistry, must contain the materials for at least a tentative solution of the problem, and it is probable that a very close solution will be provided on chemical grounds before the mathematics of the twin-sun system are sufficiently developed to be of use. This may be inferred from the fact that the precise constitution of many co-ordination compounds had been deduced on chemical grounds, before the methods of X-ray analysis and the mathematical interpretation of the results existed, and the same may be said in organic chemistry. Bohr's theory itself, for example, is conditioned from end to end, less by the necessities of mathematics and dynamics than by the periodic properties of the elements, and it is certain that, had the periodic classification not existed, no theory of atomic structure could have been developed.

The electron structure of atoms seems destined to play a large part in the future development of chemical science, and every suggestion and postulate that may help towards a coherent general theory of electronic chemistry must be welcomed. It is evident, however, that the present theories are not generally applicable to the facts. They are valuable, nevertheless, in provoking discussion and research and generally in clearing the chemical atmosphere, but it is equally evident that none of them is sufficiently well-founded and developed to constitute a bridge between the structure of the atom and the chemistry of molecules.

Chemistry Department,
The University, Birmingham

Prof. F. C. Lea, professor of Civil Engineering in Birmingham University, has succeeded Prof. Ripper in the Chair of Engineering, Sheffield.

FORTHCOMING EVENTS

Nov. 13. Society of Chemical Industry, *Edinburgh and East of Scotland Section*, in the Pharmaceutical Society's Hall, 36, York Place, Edinburgh, at 7.30 p.m. "The Constitution of Kojic 'Acid,' a γ-Pyrone Derivative formed by *Aspergillus Oryzae* from Sugar," by Dr. T. Yabuta. "The Reduction of the Mono-halogenated Phenols," by J. B. Shoesmith, M.Sc., and R. H. Slater, B.Sc. "Polarity Effects in the Isomeric ω-Bromo-toluid Acids," by J. B. Shoesmith, M.Sc., and A. C. Hetherington, B.Sc.

Nov. 13. Institution of Petroleum Technologists, at the Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "Galician-Canadian Pole Tool Fishing Methods," by A. Millar.

Nov. 13. Royal College of Science Chemical Society, College of Science, South Kensington, S.W. 7., at 5 p.m. "Some Large Metallic Crystals and their Properties," by Prof. H. C. H. Carpenter, F.R.S.

Nov. 14. Institute of Chemistry, *Leeds Area Section*, Queen's Hotel, Leeds, at 7 p.m.

Nov. 16. Institution of Rubber Industry, Hotel Victoria, Northumberland Avenue, London, S.W. 1. Annual Meeting at 6.30. Dinner at 7.30 for 8 p.m.

Nov. 16. Society of Chemical Industry, *South Wales Section*, The Technical College, Mount Pleasant, Swansea, at 7.15 p.m. Paper to be read by E. A. Tyler, M.A.

Nov. 16. The Society of Dyers and Colourists, *Manchester Section*, 36, George Street, Manchester. "Investigations into the Changes which occur in Cotton Fabrics during Calendering and Beetling," by J. Huebner and V. Malwin.

Nov. 16. The University of London, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science," by Prof. G. Dawes Hicks. (Lecture 3.)

Nov. 16. Society of Chemical Industry, *Liverpool Section*, The Overseas League, 14, Elliott Street, Liverpool, at 6 p.m. "Our Water Supplies," by E. Thompson.

Nov. 19. British Museum Swiney Lectures on Geology. A Course of Twelve Lectures on "Gem Minerals and their Uses in Art and Industry," by W. T. Gordon, M.A., D.Sc., in the Large Theatre, King's College, Strand, W.C. 2, at 5.30 p.m. Also on every Monday, Wednesday, and Friday until December 14.

Nov. 19. Royal Society of Arts, John Street, Adelphi, W.C. 2. (Cantor Lecture), at at 8 p.m. "The Cultivation of Cocoa in British Tropical Colonies," by S. H. Davies, M.Sc.

Nov. 19. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 7 p.m. "Power in Telephone Exchanges." Discussion to be opened by A. B. Eason.

SOCIETY OF CHEMICAL INDUSTRY

EDINBURGH AND EAST OF SCOTLAND SECTION

The opening meeting of the winter session was held in the Hall of the Pharmaceutical Society, Edinburgh, on October 30, 1923, when the chairman, Dr. Alexander Lauder, gave his opening address, entitled "Old and New Problems in Agricultural Chemistry."

Dr. Lauder referred to Liebig's Report on Organic Chemistry in its application to Agriculture and Physiology presented in 1840, and to Gilbert's Presidential Address to the British Association in 1880, and he traced the development of agricultural chemistry since these days, dealing in particular with researches on the supply of nitrogen to the plants. He then outlined the present position of the theories regarding absorption of salts by the soil and the question of soil acidity. This was followed by a discussion of Hoagland's recent work on the relation of "Soil Solution to Plant growth."

Dr. F. D. White also read a paper on "Galegine—an alkaloid from *Galega officinalis*."

MANCHESTER SECTION

The third annual joint meeting of the Manchester sections of the Society of Dyers and Colourists, the Society of Chemical Industry, the Institute of Chemistry and the Manchester Literary and Philosophical Society, was held on November 2, at the Textile Institute. The chairman of the Society of Dyers and Colourists, Mr. Wm. Marshall, J.P., F.I.C., took the chair, There was an attendance of about 270.

Prof. W. D. Treadwell, Ph.D., Professor of Analytical Chemistry at the Federal Technical High School, Zurich, gave an address on the recent developments of electrometric methods in analytical chemistry.

These methods were first used in chemical research about thirty years ago, in a form, however, which proved to be too complicated for technical chemical analysis. During the last few years a rapid development of electrotitrations has been brought about, consisting mainly in the application of the above-mentioned electric indicators to all kinds of chemical titrations. Prof. Treadwell described the simplifications which had been devised in the necessary equipment, so that these methods could now be used even in the most primitive technical laboratory.

The lecturer indicated the lines along which further systematic study of the behaviour of titration-electrodes was required. In numerous cases the phenomena of activity awaited explanation. In spite of the very considerable literature on surface reaction, an exact knowledge of these phenomena, based on the electrostatic attraction of the effective atoms and molecules had hardly begun to be obtained. Much work was now being devoted to these problems, and progress might be expected in the near future, which would surely help also to extend the possibilities of electrotitrations.

Electrometric methods were predestined to be carried out in the form of microtitrations. It would be interesting to try them also with molten electrolytes. Finally, electrometric methods were of value as they constitute the most reliable means for the scientific criticism of our common titrations.

SOUTH WALES SECTION

The first meeting of the session at Swansea was held jointly with the South Wales Section of the Institute of Chemistry on October 19, being preceded by a tea. Mr. F. J. Bloomer, who was in the chair, remarked that he hoped the meeting would prove to be the first of many joint ones, and called upon Mr. J. R. Green to open the discussion on "Short Cuts in Analysis."

Mr. Green described a very rapid method for the volumetric estimation of tin in solders, etc., giving results correct to at least 0·1 per cent. in 15 to 20 minutes. In contrast to the iodine method it was practically independent of large variations in volume or acidity, and the presence of a great excess of lead had no influence. It involved the use of ferric chloride, but differed from the usual process in being done in the cold, and in requiring a special indicator. This method could also be used as a rapid qualitative test for tin in presence of other metals. Mr. Green also described the "bullet-mould" test for alloys such as tin-lead and lead-antimony. This consisted in casting a series of "bullets" in a special mould, weighing several when the mould had become thoroughly heated, and, taking the mean, obtaining the percentage composition by comparison with a table of weights of "bullets" of known composition, an accuracy of 0·2 per cent. being claimed. The use of the small direct-vision spectroscope for rapid detection of traces of impurities in alloys, such as zinc in soft solders, was also mentioned. Traces of zinc, in presence of a very large excess of tin and lead, were not easy to detect chemically, but a few seconds' work with a small direct-vision spectroscope and an old arc lamp would save much tedious work and would just as effectively decide the acceptance or rejection of a consignment of metal.

Mr. C. A. Seyler remarked that he was much interested in the "bullet-mould" method of arriving at the compositions of alloys; did it originate in Germany? He could testify to the speed and accuracy of the ferric chloride method for the determination of tin. Mr. E. A. Tyler, M.A., pointed out the danger of indiscriminate use of "short cuts"; they should only be used by those familiar with the longer, standard methods. Mr. C. M. W. Grieb observed that much work had been done during the war on selective solvents for explosives, the use of which had simplified analytical methods considerably. He believed there was a big field for such methods in inorganic as well as organic chemistry.

Next, Mr. A. Grounds described a rapid and accurate colorimetric method for the estimation of pitch in fuel briquettes—a matter of great importance when the price of pitch was high. The method depended on matching the red tint obtained by extraction with carbon disulphide. The titanous chloride method for estimating iron was very little used, but it was worthy of much more general adoption.

A rapid method of estimating free hydrogen cyanide in the air was described by Prof. J. E. Coates, O.B.E., D.Sc. Some such method became a necessity in connexion with a certain process during the war, and depended upon the reaction : $I_2+HCN=ICN+HI$. The proportion of HCN varied inversely as the number of squeezes of a rubber bulb necessary to decolorise a fixed volume of standard iodine solution, the air being bubbled through it. The method, though perhaps not quite accurate, was invaluable and very rapid.

As one of the outstanding "short cuts" of recent years, Mr. J. H. Wells instanced the dimethylglyoxime method for nickel. Personally he referred the volumetric estimation of tin by iodine to that by ferric chloride, but he knew of one works where the percentage of tin in crude tin was ascertained by the ferric chloride method as described by Mr. Green, the titration being completed with a weaker solution in order to obtain greater accuracy. He endorsed Mr. Grounds' remarks as to the value of the titanous chloride method for iron.

Mr. Green, replying briefly, emphasised that "short cuts" should only be used when their accuracy had been proved by the regular methods of quantitative analysis. The indicator mentioned was made by boiling 100 g. potassium iodide and 33 g. cuprous iodide in 100 c.c. water, adding 100 g. hydriodic acid (s.g. 1·75) and a few pieces of bright copper wire, avoiding contact with air as much as possible. The titration was performed in an atmosphere of carbon dioxide, a few drops of the indicator and 5 c.c. of starch solution having been added, and the end-point was shown by the appearance of the usual blue colour. Works chemists should not be too tied down to purely chemical methods, and they should as far as possible make their own apparatus ; it was usually cheaper and often more effective than that purchased ready-made.

The meeting on November 16 has unavoidably been cancelled. Members of the Section will be duly notified of further arrangements.

CHEMICAL SOCIETY

An ordinary meeting was held at 8 p.m. on Thursday, November 1, 1923, the President, Prof. W. P. Wynne, F.R.S., occupying the Chair.

The President referred to the death of Dr. J. E. Stead, F.R.S., and spoke of the importance of his chemical and metallurgical work.

The mechanism of the combustion of hydrocarbons was dealt with by Mr. W. E. Garner, in the following paper :—

The rapid admixture of hot combustible gases with air. F. M. Cray and W. E. Garner.

The minimum temperature at which hot combustible gases will ignite, when mixed with air at high speeds, must be higher than the normal ignition temperature. It should be possible to demonstrate the cooling effect of the air if sufficiently high speeds of projection of the hot gases be attained.

Experiments have been carried out in which high explosives in steel containers, and acetylene and oxygen mixtures in glass bulbs, have been exploded in a limited volume of air. It is shown, in the case of high explosives, that the occurrence of ignition is to some extent determined by the volume of air into which the hot gases are projected, ignition occurring only when the ratio of weight of explosive to volume of air exceeds a definite value.

In the experiments with acetylene and oxygen, the velocities of projection were not sufficiently high for this phenomenon to be observed, and partial ignition occurred whatever the ratio of explosive mixture to the surrounding air. However, it was shown that the ignition was the less complete the higher the velocity of projection. Thus the greatest conversion of acetylene to carbon monoxide was attained with mixtures containing acetylene and oxygen in equal proportions, this mixture, as was shown by Dixon, possessing the highest velocity of explosion of any acetylene-oxygen mixture.

Although carbon monoxide was present in the products from the explosion of all of the mixtures investigated, including that of three parts of oxygen to one part of acetylene, free carbon was found only in those experiments where the ratio of oxygen to acetylene exceeded unity. This behaviour is in agreement with the views of Bone on the mechanism of the processes occurring during the combustion of hydrocarbons.

Sir Robert Robertson, F.R.S., made some remarks on the after-ignition of combustible gases from explosives used in mining, as propellants, and as high explosives, and gave some examples of the interval of time which had been observed and measured between the occurrence of the initial flame, proceeding from the detonation of an explosive, and the after-flame, due to ignition in air of the combustible gases, carbon monoxide and hydrogen. Referring to the work of Messrs. Cray and Garner, in which they employed explosive mixtures of gases instead of high explosives, he agreed as to the significance of the authors' observation correlating the velocity of propagation of explosion with the proportion of carbon monoxide in the gases produced. He asked whether in the case of the most rapidly-exploding mixture the fragmentation of the glass vessel was observed to be more complete than in the case of the others.

Mr. Garner, in reply, said that no difference in the character of the fragments in the bomb was observed. In some cases, however, when the explosion did not reduce the glass to powder, the amount of carbon monoxide produced was negligibly small.

The investigations covered by the following two papers were described by the author :—

The determination of surface tension from the maximum pressure in bubbles. Part II. Samuel Sugden.

An improved form of apparatus for the measurement of surface tension by the method of maximum bubble pressure is described. The method of calculation (*T.* 1922, **121**, 858) has been simplified, and it is shown that the equation

$$\gamma=\mathrm{AP}\left(1+0{\cdot}69\mathrm{r}_2\frac{\mathrm{gD}}{\mathrm{P}}\right)$$

may be used for the sizes of tubes usually employed. Here A is a constant for a particular apparatus, P dynes per cm. is the difference between the pressures required to liberate bubbles from the two tubes, r_2 cm. is the radius of the wide tube, D is the density of the liquid, and g=981 cm./sec.^{2}

To facilitate calibration a table is given showing the surface tension of benzene at each degree from 10° to 30°.

The variation of surface tension with temperature, and some related functions. Samuel Sugden.

The variation of surface tension with temperature is known to be represented with fair accuracy by an equation of van der Waals (1894),

$$\gamma=\mathrm{K}_1\theta_c\mathrm{V}_c^{-\frac{2}{3}}(1-\mathrm{m})^{\mathrm{B}} \quad \cdot \quad (1)$$

in which B is a universal constant. On the other hand, Ferguson (1916) allowed this exponent to vary slightly in order better to express the data of Ramsay and Shields (1893). Recently (1) has assumed a new interest since Ferguson has shown that the simple relation, discovered by Macleod (1923), between surface tension and density can be deduced from the modified Ramsay-Shields law and equation (1) if B is constant and equal to 1·20.

The data of Ramsay and Shields are now known to be in error owing to their correction for capillary rise in the outer vessel having been inadequate. The author now calculates the necessary correction by applying the theory worked out two years ago (*T.* 1921, **119**, 1483), and uses also the data of Walden and Swinne after correcting the Ramsay-Shields value for benzene on which these were based.

From a consideration of the available figures it is shown, for six non-associated liquids, that :—

(*a*) The variation of surface tension with temperature can be represented accurately by the formula $\gamma=\gamma_0(1-\mathrm{m})^{1\cdot20}$ where γ_0 is a constant for the substance and m is the reduced temperature :

(*b*) Macleod's relation, $\gamma=\mathrm{C}(\mathrm{D}-\mathrm{d})^4$, where C is a constant and D, d are the densities of liquid and vapour respectively, holds with remarkable accuracy up to within a few degrees of the critical temperature ;

(*c*) Van der Waals' relations connecting γ_0 with the critical constants are only approximately true ; in his equation

$$\gamma_0=\mathrm{K}_1\theta_c\,\mathrm{V}_c^{-\frac{2}{3}}=\mathrm{K}_2\theta_c^{\frac{1}{3}}\,\mathrm{p}_c^{\frac{2}{3}},$$

the "universal constants" K_1 and K_2 vary by several units per cent. among different substances.

Prof. J. C. Philip, F.R.S., enquired whether the author offered any explanation of the anomalous values quoted for the "constants" K_1 and K_2, in the case, for example, of ethyl acetate. He also asked what differences of pressure were actually measured in the apparatus described.

Dr.. Irvine Masson invited the author's observations on the fact that he had measured the surface tension of a liquid not in the presence of its vapour alone, but in that of a foreign gas. The fact that benzene was found to have the same surface tension whether wet or ordinarily dry might lend support to the speculation that any water molecules present in the benzene may be confined to the surface film.

Dr. N. V. Sidgwick, F.R.S., said that the definite effect of the presence of water on the freezing point of benzene indicated that the water molecules could not entirely be present on the surface film.

Replying, Mr. Sugden said that the pressure readings usually corresponded with about 5 to 6 cm. on an alcohol gauge, and they were read to a fraction of a millimetre ; on occasions, however, larger differences had been obtained. Referring to the constancy of values of K_1 and K_2, he mentioned that the latter, involving pressures, were (as would be anticipated) in better agreement than the former, which involved comparisons of volumes. In the case of ethyl acetate, he suggested that instability near the critical temperature might conceivably account for the anomalous results. The effect of gases on the surface tension of liquids had been examined by other workers subsequently to Ramsay and Shields ; the large differences observed by the latter had not been detected, such differences as had been measured being probably within the errors of experiment. Incidentally Mr. Sugden remarked that in investigations involving determinations of surface tension he had repeatedly found the ordinary methods of purification of organic materials to be sufficient.

Dr. R. H. Pickard, F.R.S., threw out the suggestion that with ethyl acetate pseudo ring formation was not inconceivable.

Mr. E. H. Farmer next read a paper entitled :—

Muconic and hydromuconic acids. Part III. Valency interchange in the hydromuconic system. E. H. Farmer.

In Part I of this series (*T.*, 1922, **121**, 2015) dealing with the addition of sodiomalonic and sodiocyanoacetic esters to ethyl muconate it was shown that the products possessed the general structure $RO_2C\cdot CH_2\cdot CH_2\cdot CX{:}CH\cdot CO_2R$ and not $RO_2C\cdot CH{:}CH\cdot CHX\cdot CH_2\cdot CO_2R$ as might have been expected. This constituted *in effect* addition of a 1:3-type; and in view of the difficulty in accounting for such a movement of the double bond as is necessitated if 1:2-addition be supposed to take place, it was suggested that the muconic system was to some extent comparable in mobility with the glutaconic system.

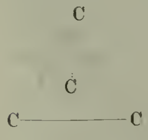
Subsequent work has shown, however, that this view is incorrect. The muconic system is static, conforms to stereo-chemical theory, and adds the components of esters at the 1:2-position. The substituted dihydromuconic esters thus produced represent in their configuration interesting instances of the effect of an equilibrium subsisting between $\Delta\alpha$- and $\Delta\beta$-dihydromuconic esters in the presence of sodium alkoxide. This equilibrium, which favours the $\Delta\alpha$-form in the dihydromuconic esters themselves, results in the conversion of the additive products under consideration into β-substituted glutaconic esters.

Prof. J. F. Thorpe, F.R.S., in congratulating the author on his experiments, remarked how elusive were the positions of double bonds when attemps were made to determine them by means of chemical reagents.

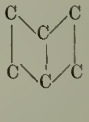
Mr. E. H. Farmer also gave an account of

Experiments on the synthesis of substances possessing the Ladenburg Formula. Part I. Derivatives of cyclo*propyl*cyclo*propane.* E. H. Farmer.

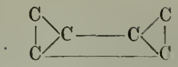
The synthesis by Beesley and Thorpe of a closed associated ring system of type I. suggested a method for the synthesis of substances possessing the Ladenburg formula. It seemed that any such synthesis must proceed by way of one of



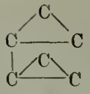
I



II



III



IV

the carbon-skeletons II, III or IV.

The present paper records the result of experiments connected with the synthesis of substances of these types, but particularly with those of type IV. The production of considerable quantities of various derivatives of *cyclo*propyl*cyclo*propane is described.

Prof. Thorpe said that it would be extremely interesting to see whether this preliminary work would eventually lead to the synthesis of substances having a Ladenburg formula. If it turned out to be possible to obtain benzene in this way, the situation would be peculiarly interesting.

ACADÉMIE DES SCIENCES

On October 15, Monsieur Lacroix described a new method of classifying rocks, and Monsieur Joubin pointed out the importance of exploring the sea from the point of view of cod and tunny fishing, the production of which affects the output of important industries. Researches on the radiochemistry of fluorescence were described by Prof. Perrin, who showed that the part played by temperature in the rapidity of action of light which he had already described in relation to methylene blue could also be traced with fluorescent blue, although the latter was 1000 times more sensitive than the former. Uranine and eosine were found to be insensitive to the effects of temperature. Monsieur d'Arsonval communicated a paper by MM. Benoit and Hellbronner, showing the existence of both physical and physiological antagonism between ultra-violet and infra-red rays. This antagonism of the infra-red was also found in respect of X-rays. Prof. Le Chatelier communicated a note by Monsieur Bonnier on the condition of decomposition of ammonium bicarbonate in the presence of water.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

There was an attendance of over 800 at the third annual meeting held in Paris, a fine result for an organisation only in existence for six years.

The meeting began on October 21 with the reception of the foreign delegates at the Hotel Majestic, followed by an afternoon devoted to music and other entertainments. The delegation sent by Great Britain, in response to the invitation of the Société, was one of the largest present, and consisted of Dr. Levinstein, who represented the Society of Chemical Industry, Profs. H. E. Armstrong, F.R.S., and J. T. Hewitt, F.R.S., delegates of the Chemical

Society, Dr. S. Miall, delegate of the Federal Council, Mr. A. R. Smith, delegate of the Institute of Chemistry, Sir John Russell, director of Rothamsted, Mr. Lomax, delegate of the Institution of Petroleum Technologists, and Mr. O. D. Lucas, of the Vickers Co.

On October 22, M. Dior, Minister of Commerce, opened the meeting formally in the great theatre of the Conservatoire des Arts et Metiers. M. Kestner, President of the Société, welcomed M. Dior and pointed out that the Congress united some of the most eminent representatives of world science and industry. After M. Dior had spoken upon the social as well as the scientific value of such meetings, M. Kestner introduced Prof. Menozzi, director of the Royal Higher School of Agriculture of Milan. In his address on "The Present State of our Knowledge of Soil Analysis and its Practical Value," Prof. Menozzi said that during the second half of the last century it was thought that by simple analysis the content of nutritive substances in the soil could be accurately determined, thus giving an exact method for determining the degree of soil fertility. This theory proved inaccurate, as soils rich in potash did not furnish sufficient potash for the plants, which grew vigorously when potassic fertilisers were added to the same soil. It was then realised that the state of the combination of the nutritive substances had to be determined, and research has since been directed towards the estimation of the substances assimilable by plants. Many solvents were tried in the effort to reproduce natural conditions, but the analytical results were too often discordant with those of practical experience. Present experience tends to suggest that inorganic food material present in the form of absorption compounds is most readily assimilable by plants, but whether it is possible or not to establish an exact method for determining the content of assimilable substances for all soils or crops, it is certain that chemical analysis gives results corresponding to practical needs by indicating the minimum quantities of nutrients that a soil should contain to be sufficiently fertile for some particular crop.

The afternoon was devoted to the meetings of the fourteen technical groups of the Congress, and later on Prof. Lindet delivered a discourse on the reconstitution of the sugar factories, distilleries and breweries in the devastated regions. Out of 213 sugar factories, 148 were destroyed, representing two-thirds of the prewar production (68,000 m. t. out of 100,000 t. of beets per 24 hours), and in 1918 only 32,000 t. of beet was available per day. Of the factories destroyed, 110 have either been rebuilt or grouped with other factories, their pre-war production now being distributed among 51 reconstructed factories. These factories are only able to produce 40,000 to 42,000 t., which, with the 32,000 t. produced by the factories that were not destroyed, makes the total 25,000 t. short of the pre-war production of 100,000 t. Out of 300 distilleries, 152 were destroyed, corresponding to two-thirds of the pre-war production. Reconstitution is slow, for industrial alcohol is monopolised by the State, and the producers wish to make sure that the sales of "National Fuel" will be sufficient to ensure a return for rebuilding their works. At present about 50 distilleries await reconstruction. Roughly, eight-tenths of the 2570 breweries were destroyed, but whereas 78 per cent of the productive capacity has been restored, the consumption still remains low.

Speaking before Group V. (Heavy Chemicals), Dr. Levinstein described the progress made by chemical industry in Great Britain, and showed the efforts made by British industry since 1914 to meet German competition. Before the same Group, M. G. Claude described new methods for obtaining cheap fertilisers. The first day was terminated by a dinner, offered by the "Bienvenue Française" to the foreign delegates and members of the Council of the Société.

On October 23 Dr. Levinstein also spoke before the Dyestuffs Group (VII) on the dyestuff industry in Great Britain, showing the great progress that had been made since 1914, and describing the steps which led to the foundation of the British Dyestuffs Corporation and the present situation. The afternoon concluded with an address by Prince Ginori Conti on the utilisation of natural steam for the production of power (*cf. Chem. & Ind.*, p. 1022).

The work of the different Groups finished on October 24, the presentation of over 150 papers having given rise to most interesting and valuable discussions, and at 4.30 of the same day the closing meeting was held under the presidency of M. Sarront, Minister of the Colonies. After various speeches had been made, Sir John Russell delivered an address on "The Influence of Micro-organisms on Soil Fertility," in which the author traced the history of the subject, starting with the work of Boussingault and outlining the valuable contributions of Pasteur and Schloesing. The enormous variations in the number of soil organisms was indicated and the reason for this discussed, and the speaker showed that the proportion of nitrates in the soil varied equally. There were two possibilities, either the absorption of nitrates by micro-organisms could be reduced or favoured, or the rate of production of nitrates could be increased. It was for this reason that partial sterilisation was developed. Antiseptics have been applied on a large scale in France for this purpose by Truffaut, but in England nitrogenous fertilisers are cheaper than antiseptics, and no substance had been found which increased the proportion of nitrates in the soil more cheaply than nitrogenous fertilisers.

At 8 p.m. 300 members met at a banquet held at the Palais D'Orsay, under the presidency of M. Roux, who replaced the Minister of Agriculture. During the speeches, Prof. H. E.

Armstrong pointed out the value of the Congress and of collaboration between the chemical societies of France and England, after which M. Roux thanked the foreign scientists who had attended the Congress. The evening was then devoted to conversation and dancing.

Visits to factories commenced on October 25, when the members visited the factory of Felix Potin at Pantin, where they saw different methods of treating wine. After refreshments, the members drove to the Chateau de Noisiel, where Monsieur G. Menier entertained them to dinner. Various speeches were made emphasising the importance of chemistry to modern industry, and M. Menier described the development of the Menier chocolate works since their foundation in 1816 to the present production of 65,000 kg. of chocolate per day. The members were then conducted round the works, where all the different stages of the manufacture of chocolate were inspected.

A visit to Rheims was paid on October 26, the visitors being received by Cardinal Lucon, who described, in moving terms, the martyrdom of the town and cathedral from September, 1914, until its liberation in 1918. Prof. Matignon, in thanking the Cardinal for receiving them, delivered a discourse in which he showed that modern research workers continued the great traditions of the thirteenth century, a period of expansion during which the intellectual development took place of which the cathedral of Rheims was a symbol. Subsequently visits were paid to the antique cellars of the well-known firm of Pommery, and after the various processes for producing champagne had been explained to the visitors, Messrs. Pommery entertained them to a lunch, presided over by M. G. Vidal, the Under-Secretary of State for Technical Education. After lunch the members motored to the establishments of Heidsieck, whose products they were able to appreciate whilst enjoying a magnificent view. The excursion terminated with a visit to the Pompell Fort, where an officer of the War Ministry outlined the history of this field of battle, thus ending the Congress on a heroic note.

BRITISH ASSOCIATION OF CHEMISTS

The sixth annual general meeting was held at the University of Birmingham on October 27, Dr. H. Levinstein presiding.

The Council reported that the membership had declined from 1095 to 912 owing to the economic situation. It was decided not to take definite action in respect of legal redefinition of the term "chemist," as it was felt that no useful purpose would be served until there was greater co-operation between the various chemical organisations, coupled with the education of the general public by chemists themselves. The report was adopted, and the following were elected officers for the ensuing year:—President, Dr. H. Levinstein; vice-presidents, Mr. W. E. Kay and Mr. F. Scholefield; hon. treasurer, Mr. H. E. J. Cory; hon. general secretary, Mr. I. Boodson; hon. registrar, Dr. D. Bain; and hon. editor, Mr. A. Merrick.

The members were entertained to tea by the Chemical Department of the University, and then inspected an exhibition of specimens and apparatus from the Research Section. The annual dinner, which was held in the evening at the Queen's Hotel, Birmingham, was attended by a representative company.

In proposing the toast, the "B.A.C.," the president observed that if new industries were developed and a bid made to secure the world's markets there would be an opening for chemists which hitherto did not exist, and the great work which was being done at universities would find its due reward in the creation of positions for chemists.

Mr. E. R. Redgrove, in submitting the toast, "Kindred Societies," said the Society of Chemical Industry came nearer to the class of chemists they represented than any other; and it did splendid work in letting them know what was happening. The Chemical Society, which was the more academic, also helped them considerably. The Institute of Chemistry, with which he hoped they would always be friends, had definite functions which were entirely separate from theirs. Dr. E. B. Maxted, responding, remarked that no matter what society they belonged to, they all felt the ties of kinship and of interdependence of one society on the other.

Dr. F. W. Kay proposed "The Universities and Seats of Learning," and coupled the names of Prof. Morgan and Dr. Friend. He said he believed that, unless they could speak for the profession as a whole, progress would be slow. As a society they looked to the Universities to maintain the supply of highly-trained chemists. Prof. Morgan, in reply, observed that the success of the Association was bound up with that of the Universities. If the chemical industries dwindled, then our chemical schools would disappear to some extent. That was why it was so important that the Association should do its best to maintain the dignity of the chemical profession. Dr. J. Newton Friend also replied.

Mr. N. P. Booth, proposing the toast of "The Guests," said that the Association supplied the means by which it could do things for chemists which the Institute was unable to perform. Dr. Miall replied briefly.

We regret that through inadvertence the name of Mr. J. L. Baker is given on page xvi of *Chemistry and Industry* of November 2 as vice-chairman of the London Section of the Society. Mr. Baker's period of office recently expired and Mr. E. V. Evans was elected to succeed him.

CORRESPONDENCE

THE CHEMIST AND THE PUBLIC

Sir,—We have been told repeatedly, and we were told again at the Chemists' dinner held on Wednesday last at the Hotel Victoria, that one of the chief difficulties with which the professional chemist has to deal is the indifference, and even the ignorance, of the general public, and of public authorities, with regard to the social value and industrial importance of chemistry. Such a function as was held on Wednesday last, under the joint auspices of the Chemical Society, the Institute of Chemistry, and the Society of Chemical Industry, might reasonably have been expected to have been of some value as an aid towards explaining and overcoming this difficulty. No doubt something was accomplished from the mere fact that the Dinner was arranged and held, but those who hoped for some evidence of real progress towards a fuller public recognition of chemists and chemistry must have come away somewhat saddened. The vocal musical entertainment provided was excellent, but the unassisted vocal contributions can only be described as in this regard disappointing.

The pharmacists may accept with justifiable pride, as Mr. Woolcock did on their behalf in his witty address, the tribute to the advances made of recent years in their developments of chemical knowledge and practice paid by the right honourable gentleman who proposed the toast of "Chemistry and the Nation." Neither the academic nor the industrial chemist, surely, will be disposed to feel jealous of any recognition given to pharmacy. It seemed strange, however, that it should have been left to Sir William Pope, in replying, and to Mr. Woolcock, in proposing another toast, to point out that there are other equally vital and important provinces of chemistry, and that the great contributions of chemists to the country's war effort were not mainly, or even largely, the compounding of new and more easily absorbed varieties of various medical remedies.

Can we feel other than saddened and disappointed to realise, as all who attended the dinner must have done, that even the proposer of the toast of "Chemistry and the Nation" was apparently neither familiar with nor impressed by the vital social importance of chemistry, both for peace and for war ?

None of the other speeches of the evening afforded much opportunity, even had the speakers been inclined to form a mutual admiration chorus, of stressing this importance ; unfortunately neither did they do much to formulate positive suggestions for steps to secure that recognition which is felt in some degree to be due to chemists, but in a much greater degree to be necessary to our national safety and prosperity. If criticism of our leaders be permissible, it may be said that more than one of the speeches of the evening indicated rather a trace of mutual recrimination than a large measure of that wholesome confidence and co-operation which is so essential if chemists are to secure that place in the public estimation which their works justify. The University-trained chemist, fresh from the receipt of his academic honours, may not possess all the qualities necessary to fit him for the immediate control of a big industrial undertaking ; but is it reasonable of Dr. Armstrong to complain of what is surely only obvious, and indeed proper, and to blame the University for having turned out a well-trained chemist rather than a man possessed of some smattering of chemistry, some similar smattering of economics, and various doubtful business qualifications ? By their works will chemists be known, but they must speak with one voice in calling attention to those works. We must have trust in ourselves before we can expect trust from others, and workers in every department of chemical science and industry must realise the importance and necessary place of other departments if we are to build up such an harmonious structure of co-ordinated chemical activity as will of itself secure for us the recognition and confidence of the general public.—I am, Sir, etc.,
S. I. Levy

59 and 60, Broad Street Avenue,
London, E.C. 2
November 1, 1923

THE CHEMICAL ENGINEER

Sir,—The re-opening of the discussion as to the nature and properties of the chemical engineer, who he is and what he is, which has followed Mr. Gray's article in your issue of October 5, prompts me to lay before you some views on this subject, which have been crystallising slowly in my mind, and have only recently reached something approaching the solid state. Let me say at once that I agree with nearly everything that Mr. Gray said, and a little more.

Prof. Donnan, in the Faraday Society discussion in 1917, gave an admirable summary of the kind of knowledge which a person who intends to interest himself in the erection or running of chemical factories should try to acquire. His attainments should include a knowledge of applied mechanics, engineering drawing, thermochemistry, thermodynamics and a long list of other matters. How much knowledge of these things he is to possess is not very clear. Prof. Donnan describes this individual as an engineer-chemist.

Now, Sir, the man with a real working knowledge of all these things is, and is likely to remain, a rarity. If he could be found, it would be difficult to know what to do with him. Probably the best thing would be to form a company with a large capital to finance the working out of his ideas. If, in addition to the attainments mentioned, he possessed common sense, he would no doubt, if necessary, form the company himself. But I do not think he would describe himself as an engineer. I suggest that Prof. Donnan's advice is rather of the nature of a counsel of perfection, whilst heartily agreeing that any man in a responsible position in a chemical factory should have some acquaintance with these things.

Turning, however, to those ordinary mortals who insist on calling themselves chemical engineers, I think the first point to notice about them is that *they baptised themselves*. No one would worry about them if they would do their work quietly. That is my first point.

My second point is that, *taken as a whole*, the engineering element in a chemical factory is of secondary importance and secondary difficulty. It is indispensable in the sense that everything that forms part of the factory is indispensable, but most of it is not difficult, and the attainments which it requires are not of a very high order. Let us consider what they amount to.

The first step in starting a chemical manufacture is the design of the process, and this must be done by a chemist. It bristles with real difficulties, and demands considerable attainments. The chemist, if he has any common sense at all, will certainly design the process from the point of view of commercial practicability. That is to say, he will be guided first of all by the existence of markets for the products and the necessity of producing them at a cost which renders the commercial position advantageous. That is the *raison d'être* of the business. It is merely common sense, and requires no knowledge of engineering, unless a rough acquaintance with the cost and life of plant be reckoned as such. Information as to the kind of plant available for a given purpose without special design may be acquired readily by making enquiries of plant manufacturers. This is a matter for the draughtsman, who can always obtain it in a few days, and very often can give it at once.

The next step is the design of the plant, and here sometimes, but not always, considerable difficulties arise. I submit that these, in so far as they affect the engineering side of the question, are generally connected with one or both of two factors, namely, choice of materials and heat transmission. The choice of materials has to be made by the chemist, and the chemist, if he is a knowledgable person, probably knows as much about heat transmission as the engineer. He is, at least, as well able to find out about it.

What, then, are the duties of an engineer in a chemical factory? I suggest that they are as follows (assuming that the site has been chosen) :—

(1) To design and erect the buildings.
(2) To provide any power that may be required.
(3) To design, if necessary, and erect the plant to the instructions of the chemist.
(4) To superintend repairs and maintenance.
(5) To possess common sense, and a general acquaintance with chemical nomenclature.

Now, none of these duties requires any exceptional knowledge or attainment. All that is required of the chemical factory engineer is that he shall be able to lay foundations and erect buildings, boilers and plant.

Mr. J. H. West, in your issue of October 28, says that the chemical engineer is the chemist's best friend, but I think it would be more accurate to describe the chemist as the best and all-necessary friend of the chemical factory engineer, as I prefer to call him. The latter, when he is a reasonable being, occupies a place of importance and some honour in the chemical factory. But if he becomes infected with militant ideas, arms himself with a bookshelf of makers' catalogues, and represents himself as the *deus ex machina* of the chemical industry, he becomes the "compleat" example of the gentle art of "swank."

There is, however, another type of chemical engineer, who requires to be taken much more seriously. I refer to the inventor of *really new* forms of plant. He is a rare bird, and not to be pigeon-holed. He may be a chemist or a physicist, or an engineer. Occasionally he hails from an office. Whether, collectively, he calls himself a chemical engineer, I do not know.*—I am, Sir, etc., A. Jaques

Liverpool,
Nov. 3, 1923

---

* The above was written before the appearance of the Editorial in your issue of November 2, with its very suggestive question as to whether Nobel was a chemical engineer.

THE DIFFICULT ENGLISH

M. the Editor,—I read your first note, so complimentary to our language and to the French, then I turn me to your first article and read the beginning sentence and ask myself what means, "I find myself in agreement with 'X' in admitting that Werner's theory of co-ordination had been very slow in receiving the recognition it deserves." I think of my school-time, when I was taught the rhetoric, as we call it—how to use grammar and to express myself in the way correct. I ask me how a theory can be slow to receive or receive at all. It is, as you have well said, the writers they seem so often to leave the expression of their thoughts to chance. It is very difficult for us strange people to know what they mean, when they write in this way and—do you not call it or is it the Professor Bone?—"activate" the passives. It is the way of your good contributor, I think; is he so much gazing at the beautiful, naked, proton of the hydrogen—fortunately for our *Garçonnes* this is not yet come to Montmartre—that his eyes are blind and he does not look at the words, the shine is so much in his eyes ? I would ask, as well, what he mean when he write—" none of the chlorine can be precipitated by silver nitrate." I have not suppose chlorine is made of ones.

It is sometimes very funny how you write. I see, in the second article in your beautiful journal, the gentleman say: " It is always helpful if one can look round." Perhaps some of your chief chemists think so, but in France we cultivate the sport to keep the spare figure. Thank you, Sir, for your try to make the English that it can be understood. It can be very beautifully wrote. For example, if you read the English of M. Lafcadio Hearn, of the Crime of Sylvestre Bonnard, it is as beautiful as the French of Anatole France, the most perfect of the French writers, is it not so ?—Your servant much devoted,

PARISIAN

PERSONALIA

The Board of Trade has appointed Dr. A. T. de Mouilpied, of the British Dyestuffs Corporation, Ltd., to be a member of the Dyestuffs Industry Development Committee, in place of Dr. Herbert Levinstein, who has resigned.

Prof. W. H. Perkin, F.R.S., who for some time has controlled the research work of the British Dyestuffs Corporation at Oxford, has undertaken to advise and supervise the company's research staff at headquarters.

The Nobel Prize for Medicine for 1922 has been divided between Prof. A. V. Hill, University College, London, and Prof. O. M. Meyerhof, of Kiel University. Prof. Hill has devoted particular attention to the nature of nervous excitation, the carriage of oxygen and carbon dioxide by the blood, and the physiology of muscular movement. It is also announced that the Nobel Prize for Medicine for 1923 has been awarded to Dr. Banting and Prof. Macleod, of Toronto, for the discovery of insulin. According to a press communication Dr. Banting regrets that there was no mention in the award of Dr. Best, as he had an intimate part in the discovery of insulin. Dr. Banting, therefore, declares he will share the award with Dr. Best.

Professors Moureu and D'Arsonval have been promoted to Grands Officiers of the Legion of Honour, on the occasion of the centenary of Pasteur.

* * *

The following deaths are announced from Germany: Prof. A. Böttcher, formerly director of the Thuringian State Technical Institute; and P. Bartel, director of the Deutsche Keramische Gesellschaft. From Austria the death is recorded of Dr. A. Kutiak, well known in chemical circles.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Nov.* 1)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia . .	Iron and steel	471
„ . .	Alloy steel couplings . .	12434/E.D./ E.C./2
„ . .	Fibre for insulators . .	12428/E.D./ C.C.

TARIFF CUSTOMS EXCISE

Argentina.—The use of salicylic and boric acid in foodstuffs and beverages is prohibited.

Australia.—A dumping duty has been placed on German potassium permanganate crystals.

Canada.—Canada has adhered to the Industrial Property Convention as from September 1, 1923. A copy of the Order in Council applying the relevant provisions of the Patents and Designs Acts may be seen in the Patent Office Library.

Dominica.—Reduction has been made in the import duty on soap.

Finland.—The import duty on silk has been reduced, and the export duty on paper abolished.

Germany.—A list of goods subject to increased import duties is given in the current issue.

Gilbert and Ellice Islands.—An export duty at the rate of £1 per ton is payable on copra.

Rumania.—No special permit is required for the export of glassware and gypsum.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No material changes have taken place in the heavy chemical market either in demand or prices.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 9d.—4s. 3d. per carboy d/d.
Acid Nitric 80° Tw.	£21 10s. per ton makers' works.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 65s. f.o.r. makers' works, with slight variations up and down.
Acid Sulphuric, 94% Arsenical	£6 per ton makers' works.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

The general outlook of the wood distillation industry is encouraging.

Acetate of Lime—	
Brown	£11 5s.—£11 10s. per ton d/d. Demand steady.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£10 per ton, according to grade and locality of market.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 3d. per gall. 60% O.P. Steady market.
Solvent	6s. 3d. per gall. 40% O.P. Steady.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£41 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1½d.—1s. 2d. per lb. Fair inquiry. Good business for prompt delivery.
Crude 60's	3s. 6d.—3s. 8d. per gall. Market quieter.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Firm, with good demand.
Acid Cresylic	
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 6d.—2s. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—10d. per gall. Plenty of enquiries.
Unstrained	8½d. per gall.

Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall. d/d. buyer's works.
Pure	1s. 9d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Good business being done.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d. per gall. Market sluggish.
Solvent 90/190	1s. 2d.—1s. 3d. per gall. Very little business.
Naphthalene Crude—	
Drained Creosote Salts	£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9 10s.—£11 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	132s. 6d.—140s. per ton, according to district and time of delivery. Several inquiries. Market firm.
Pyridine—90/140	22s.—22s. 6d. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

Dyestuffs business has been better during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Quieter.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Better demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The shortage of spot supplies is beginning to be felt seriously and prices are in consequence considerably higher for a few of the pharmaceutical chemicals which are in regular demand.

Acid, Acetic 80% B.P.	£47 10s. per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 9d. per lb. In strong demand.
Acid, Benzoic	2s. 9d. per lb. for ordinary quality. No B.P. quality on offer.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Citric	1s. 4½d. per lb., less 5%, for ton lots. Poor demand.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	7s. 6d. per lb.
Acid, Salicylic	2s. 4d.—2s. 7d. per lb. Firm market.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1¾d. per lb. less 5%. Home trade poor. Raw material slightly dearer.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 2s. 3d. per lb. Small stocks and large orders from abroad.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	3s. 6d. per lb. for English make.
Ammon. Carbonate B.P.	£32 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Demand very poor
Barbitone	17s. per lb. Neglected.
Benzonaphthol	5s. per lb. Quiet.
Bismuth Salts	A steady market. Carbonate 13s., Nitrate 6s. 11d., Salicylate 10s. 5d., Subgallate 9s. 6d., Citrate 11s. 7d., Oxide 14s. 5d., Subcholride 12s. 8d., Subnitrate 11s.
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.

Bromides—		
Potassium	7d. per lb.	Remain very firm.
Ammonium	8d. ,, ,,	
Sodium	7½d. ,, ,,	

Calcium Lactate	2s. 6d. per lb. for best English make.
Chloral Hydrate	4s. 3d. per lb. Position very firm.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	9s. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 12s. per lb.
Hexamine	4s. 3d. per lb. Steady market.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	2s. 2d. per lb. for cwt. lots. 2s. 3d. for 28 lb. lots. Prices recently reduced.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£77 10s. per ton, less 2½%.
Heavy Commercial	£27 per ton. less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 72s. 6d. per lb.
Methyl Salicylate	2s. 10d. per lb. for carboys. Very scarce. Higher values expected.
Methyl Sulphonal	14s. 6d. per lb.
Morphine and Salts	Prices again advanced owing to dearness of opium. Alkaloid: Cryst. 14s. 8d., Precip. 14s. 5d., Acetate 11s. 6d., Hydrochlor. 11s. 6d., Sulphate 11s. 6d., Tartrate 14s. 5d. per oz.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 5d. per lb.
Phenacetin	7s. 6d. per lb. Supplies short. Market excited.
Phenazone	8s. 9d. per lb. Remains very scarce.
Phenolphthalein	7s. 6d. per lb. Very firm. Shortage imminent.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Fair business passing.
Potass. Citrate	1s. 11d.-2s. per lb. Recently reduced.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	15s. 8d.—15s. 11d. per lb. Good steady market.
Potass. Permanganate	10d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. per lb.
Salol	4s. per lb. In better supply.
Sod. Benzoate	2s. 9d. per lb. Little inquiry.
Sod. Citrate, B.P.C., 1923	1s. 11d. per lb. for cwt. lots. Recently reduced.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 9d. per lb., and Crystal at 2s. 11d. per lb. Firm and very active.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	15s. per lb. In very small demand.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	3s. 6d. ,, ,,
Cinnamic Aldehyde Natural	20s. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	10s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s. 9d. to 13s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	18s. 6d. ,, ,,
Linalyl Acetate	18s. 6d. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Ketone	47s. 6d. ,, ,,
Musk Xylol	13s. 6d ,, ,,
Nerolin	4s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,
Rhodinol	60s. ,, ,,
Safrol	2s. ,, ,,
Terpineol	3s. ,, ,,
Vanillin	22s. 6d.—23s. per lb. Firm and steady demand. Raw material dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 10½d. ,, ,,
Bergamot Oil	13s. 3d. ,, ,, spot.
Bourbon Geranium Oil	37s. ,, ,,
Camphor Oil	80s. ,, ,,
Cananga Oil, Java	9s. 6d ,, ,,
Cinnamon Oil, Leaf	4¾d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.

Citronella Oil—	
Java 85/90%	4s. 9d. „ „
Ceylon	Very little on offer, too many parcels arriving containing spirit. These have been seized by the Customs.
Clove Oil	9s. per lb.
Eucalyptus Oil 70/75%	2s. 9d. per lb.
Lavender Oil—	
French 38/40% Esters	26s. per lb.
Lemon Oil	2s. 10d. per lb.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil	24s. 6d. per lb.
Peppermint Oil—	
English	70s. per lb. Market very unsteady.
Wayne County	15s. 6d. per lb. Market very unsteady.
Japanese	12s. per lb. Market very unsteady.
Petitgrain Oil	8s. 9d. per lb. Dearer.

TRADE NOTES

State Aid for the Chilean Iron and Steel Industry

A Bill has been presented to the Chilean Congress with the object of providing State aid to the iron and steel industry in Chile and encouraging foreign companies to work Chilean iron-ore deposits. A translation of the Bill may be seen by British firms at the Department of Overseas Trade, 35, Old Queen Street, London.—(*Ref.* 8704/*F.L.*)

Iron Production in Europe

The recent changes of boundary between Germany and France have greatly changed the positions of these countries compared with that obtaining before the war. In 1913 Germany produced 16,764,000 t. of pig iron, Great Britain 10,425,000 t., and France 5,207,000 t. If the present boundaries, however, had been in force, these figures would have become 10,916,000 t., 10,425,000 t., and 9,071,000 t. respectively, omitting the output of the Saar region. Thus France has a capacity practically equal either to that of Great Britain or Germany. Moreover, taking into consideration iron works controlled by French capital in the Saar region, Luxemburg, Belgium and Czechoslovakia, the total output of pig-iron under French control is 18,000,000 t., and if the productive capacity of the occupied area is included this figure becomes 26,000,000 t., or three-fifths of the total productive capacity of Europe.

Unemployment in Germany

According to a report of the United States Commercial Attaché, Berlin, dated October 10, industrial production in Germany was then less than at any time since 1919. Total unemployment was then estimated unofficially at 1,200,000, and part-time was being worked by between two and three million, of which 40 per cent. were working only 24 to 33 hours per week.

Developments in Germany

A correspondent informs us that important factories are being built in the neighbourhood of Essen, where Hugo Stinnes is building a large window-glass factory, which will utilise an American patent for the production of window-glass by means of rolling machines. In connexion with this factory works are being erected to utilise a new method described as the turning drum system for distilling coal.

German Potash Production

Sales of potash during the first nine months of this year were 788,900 m.t., or roughly 200,000 t. less than in the same period of last year. In October exports were reported to have diminished further as the German mines were feeling the competition of the Alsatian producers. It is proposed to amalgamate the four potash consortiums, *i.e.*, Winterschell, Gluckauf, Deutsche Kaliwerke and Ronneberg, under one group.

Japanese Heavy Chemicals and Dyestuffs Market in 1922

The Japanese market for heavy chemicals and dyestuffs improved considerably during 1922 because the comparative prosperity of the textile industries maintained the demand for dyestuffs and the large surplus stocks of industrial chemicals carried over from the post-war speculative period became depleted. For heavy chemicals, other than ammonium sulphate, Japan is now turning to England and Germany in preference to the United States, as better prices can be had from these countries. The United States, however, supplied over 90 per cent. of the crude ammonium sulphate imported at Kobe in 1922, and the market of this chemical is now practically confined to the United States. England supplied about 75 per cent. of the imports of soda ash, the remainder coming from South Africa. The bulk of the carbolic acid used in Japan is now being supplied by Great Britain. Germany has recaptured from the United States most of the trade in aniline dyes, and even in artificial indigo, which has not been so completely overshadowed by German supplies. Germany supplied over 50 per cent., the remainder coming from Great Britain and the United States. It is expected, however, that when the exchange becomes more normal in Germany, and the high *ad valorem* duty on imported dyes has been reduced, it will not be so difficult to sell dyestuffs in Japan.—(*U.S. Comm. Rep.*, *Aug.* 20, 1923.)

Trade Notes from France

The consequences of the Japanese disaster are being felt by various branches of the French trade and industry. The market for silk is very uncertain and prices of camphor, menthol, peppermint oil and agar have almost doubled. It is not yet possible to foresee what the effect will be on the export trade.

It is announced that the Société de la Soie Artificielle de Tubize proposes to increase its capital in order to establish a factory for the manufacture of cellulose-acetate silk at Petit Quevilly, near Rouen.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to application for licences under the Dyestuffs (Import Regulation) Act, 1920, made during September has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 457, of which 311 were from merchants or importers. To these should be added the 34 cases outstanding on September 1, making a total for the month of 491. These were dealt with as follows:—

Granted—342 (of which 300 were dealt with within 7 days of receipt). Referred to British makers of similar products—79 (of which 65 were dealt with within 7 days of receipt).

Referred to Reparation supplies available—30 (all dealt with within two days of receipt).

Outstanding on September 30, 1923—40 (all dealt with at meeting of the Committee held on October 5).

Of the total of 491 applications received, 395, or 80 per cent. were dealt with within 7 days of receipt.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, NOVEMBER 16, 1923 No. 46

EDITORIAL

IT is pleasant to watch for many years the progress of really high-class work carried on for the benefit of humanity, to see from the early days the improvements which are the result, to notice the gradual growth of the esteem which the leaders of the work inspire, and at length—often after an unduly long interval—to find signs of that recognition which is valued by modest and retiring men. About a quarter of a century ago the Home Office was gravely concerned by the amount of industrial disease, and many people of every variety of political faith urged that steps should be taken to protect the health of the workpeople; Sir Charles Dilke, Mr. and Mrs. H. J. Tennant, Miss Tuckwell, Miss Mona Wilson and some other devoted workers spent a very great deal of time and energy in this cause. The appointment of Dr. T. M. Legge as Chief Medical Inspector at the Home Office was a fortunate choice, and his efforts were immediately successful. The medical staff at the Home Office has always been and still is very small, but Dr. Legge is recognised throughout the world as one of the most learned and reliable of those who have studied industrial disease and dangerous trades. It is, therefore, most appropriate that he should have been awarded the Bisset-Hawkins Memorial Medal given by the Royal College of Physicians triennially to the medical practitioner who has most signally distinguished himself in promoting sanitary science and public health. The medal has in the past been awarded, amongst others, to Sir Ronald Ross, Sir Patrick Manson and Sir Arthur Newsholme. Dr. Legge has frequently attended meetings of the Society of Chemical Industry and taken part in the discussions. When he has done so, he has displayed the tact, caution and sincerity which are characteristic of him, and all who have come in contact with him or his work know that the honour he has received is really well deserved.

* * *

A few months ago, Professor A. Smithells, F.R.S., resigned the chair of chemistry at the University of Leeds which he held since the retirement of the first professor there, Sir Edward Thorpe. It is intended to commemorate his services by the establishment of a Fellowship or Scholarship at that University, and Professor J. W. Cobb, one of his old students, will be glad to hear from chemists who wish to take a part in the establishment. Professor Smithells played an important part in the development of the University, in organising its social activities, in interesting the citizens of Leeds in the work of the University, as well as in teaching chemistry; these pursuits occupied practically his whole time and left him few opportunities for that research which he and other chemists so much value. But much important spade work has to be done in the formation of a University College and its growth into a modern university, and those who remember the earliest days of science at Leeds—and we are old enough to count ourselves in the number—know that much of the work is of a nature which makes no obvious impression on the public, whether lay or academic. The growth of modern universities is an interesting problem and dates back to a period when there was a great revival of intellectual activity, partly due to the exceptional controversial interest occasioned by Darwin and Huxley. That stimulus is now spent and is not likely to arise again, but the necessity for science in industry has, to a large extent, taken its place as a factor in scientific education.

* * *

Not the least of the many signs of the growth of a more corporate feeling among chemists is the readiness and interest with which our readers have discussed affairs of importance to their profession in our correspondence columns. Reading, it has been said, maketh a full man, conference a ready man, and writing an exact man; so it may be surmised that the discussion of topics of importance to chemistry will bear the ripest of fruit in due season. In a letter which we publish in this issue, Mr. Foster Sproxton suggests that the Sections of the Society of Chemical Industry should consider any proposed legislation that appears likely to affect the interests of chemists or chemical industry. Some action is eminently desirable, but it seems rather excessive to require our members to read the five bulky numbers of "Hansard" which appear every week during session time, or even the smaller, but much less entrancing, monthly list of Stationery Office publications. It may be of interest to point out that a modest effort has long been made to present a digest of material in the Parliamentary Debates that may interest our readers, and that impending legislation is noticed as completely as is possible. Discussion such as Mr. Sproxton advocates is certainly needed, but for any proposal to be effective it would require the support of the whole profession. We welcome the suggestion that such proposals should be criticised constructively in these columns, and if we refer to the fable about the man who investigated the breaking strain of a bundle of sticks, it is in no carping spirit but with a genuine desire for the unity of the profession of chemistry.

* * *

It seems from the club gossip and the remarks in the daily newspapers that we are threatened with a General Election. Alas, what exertion is stirred up for candidates and electors! How many Members of Parliament will have an unfortunate fate! Even now Lloyd George gets ready his statistics, his Rolls-Royce and his wrath. Can you not see Baldwin and Asquith and Ramsay MacDonald hard at it, and fearless Birkenhead, skilful in the fight, *sive opus est imperitare equis, non auriga piger?* Which seems to allude to some earlier prowess. Alfred Mond, you will also come across, and Austen and Neville, the sons of a famous warrior. But this election perturbs us not. Do not ask us, for it is no business of ours, what end is fated for this party or for that. Whatever party is returned to power, we must put up with it and it will hardly come up to our expectations. Whether this is the last General Election we shall see, or whether many others will in the future interfere with all trades except printers and bill-stickers, let us be happy and wise, sip our Volnay and cut down our hopes of prosperity, which our portion on earth is too brief to realise. Even as we write, time flies; let us make the best of this weekly number and hold over as little as possible for the next. Let no one be afraid that we shall make use of this column or allow other contributors to desecrate this journal for political purposes; Horace says somewhere, if we err not, that you should have infinite confidence in those who attain the ripe age of forty and we have done this and more. Far removed from the ignoble, political strife, we aspire to literary fame, the memorial more enduring than brass and loftier than the pyramid in its royal site. We shall not die, our reputation will grow, so long as Cambridge professors assist the Girton graduates up the steep path of science, *dum scandet cum tacita virgine Pontifex.*

SCIENTIFIC METHODS OF MAKING CONCRETE

BY PROF. DUFF A. ABRAMS[*]

INTRODUCTION

No other type of structural material has such a wide appeal as concrete. Practically every variety of engineer comes into contact with some phases of its uses. The almost innumerable uses of concrete constitute one of the most remarkable features of our modern industrial life. If we wish to build a foundation deep under the ground to support a sky-scraper, concrete is the material used. If we wish to construct a reservoir for irrigation, municipal water supply or flood control, a concrete dam solves the problem. If we wish to carry our railroads safely across streams, the concrete bridge at once comes to mind. If we wish to carry heavily loaded trucks at a rapid rate over our highways, the concrete pavement furnishes the means.

Concrete consists of an intimate mixture of Portland cement, water and aggregate which is permitted to set and harden under proper conditions. Cement is a most important constituent of concrete, but it should be understood that both the *quality* and quantity of the other constituents must be given consideration. So widely used is concrete that methods of improving its quality no longer appeal to engineers alone, but have become a matter of public policy, and hence of general interest.

As concrete is strong under compression and comparatively weak under tension, this led to the introduction of iron and (later) steel bars to take the tensile stresses. As a result of the general interest in the subject a great deal of experimental work was carried out in the United States and Europe during the decade beginning about 1903. Much valuable information was secured from the many studies of reinforced concrete, and engineers soon became able to design members and structures of reinforced concrete with the same degree of certainty that was recognized in steel, timber or stone masonry structures.

Up to about 10 years ago most attention was given to tests of *cement* and *reinforced concrete*, the underlying idea being that a good cement was the sole requirement of good concrete, and that the stress distribution was the most important factor in a reinforced concrete member. It gradually became apparent that the manufacture of cement was surrounded by such safeguards that rigid tests were no longer necessary, and that we knew a great deal more about *reinforced concrete* than we did about *concrete*. This last statement may seem somewhat anomalous, but it is literally true. If we make certain assumptions concerning the quality of the concrete, the strength and behaviour of a reinforced concrete member or structure can be

[*] Professor in Charge Structural Materials Research Laboratory, Lewis Institute, Chicago.

calculated with considerable accuracy; however, no one could at that time estimate with any degree of certainty the quality of *concrete* which would result from mixing certain materials together and testing in a given manner.

It was the desire to learn more of the properties of concrete that led to the organisation of the Structural Materials Research Laboratory in 1914. Since 1916 the Laboratory has been conducted through the co-operation of Lewis Institute and the Portland Cement Association. Lewis Institute is an endowed educational institution located in Chicago; the Portland Cement Association is an organisation of the cement manufacturers in the United States, Canada, Mexico and Cuba, with the aim of extending and improving the uses of concrete. The Laboratory is now one of the best equipped in the United States. About forty engineers, chemists and assistants give their entire time to this experimental work, and the results are made available to those who may be interested through papers read before engineering societies, and by a series of bulletins and circulars published by the Laboratory.

This paper will deal principally with methods of proportioning concrete, with brief references to other phases of our experimental work which have been completed. It should be noted that our tests have thus far been confined almost entirely to *concrete;* in other words, little or no attention has been given to *reinforced concrete*.

Design of Concrete Mixtures

A number of important lines of investigation may be grouped under the general head of studies of design of concrete mixtures. These studies have to do with the effect of varying the relative quantities of the constituent materials, grading of aggregates, etc. Many different methods have been used and several theories have been advanced as a basis for proportioning concrete. We have the present custom (almost universal, I regret to say) of proportioning concrete by arbitrary quantities; that is, we use, say a 1-2-4 mix regardless of the characteristics of the aggregate materials, with no attention whatever to the quantity of mixing water used and take little account of the strength of the resulting concrete. Needless to say, this method is extremely crude, and does not recommend itself to thoughtful engineers.

The minimum-density-of-aggregate method has been advocated and used to some extent. Here the endeavour was to grade aggregates in such a way as to give an aggregate mixture of maximum density, and then to supply the quantity of cement that was considered necessary to produce concrete of the desired quality.

Another method is based on the voids in the aggregates. The voids in the coarse aggregates are determined, a sufficient quantity of sand is supplied to fill these voids, then a sufficient quantity of cement added to fill the voids in the combined aggregates. This is a little more rational than the purely arbitrary method. It, however, has no scientific basis. It will, in general, give fairly good concrete, but our investigations have shown that the voids in the aggregates do not constitute the determining factor in concrete mixtures.

Experimental Studies of Proportioning

A great deal of experimental work has been done in endeavouring to arrive at a proper basis for proportioning concrete. Much of the early work of R. Feret[1], a French engineer, was devoted to a study of this problem. Feret confined his studies almost entirely to sand mortars; consequently it is not easy to apply his methods directly to concrete mixtures. A. Hazen[2] did some interesting work in his studies of sands for water filtration. He made use of the "effective size" and "uniformity coefficient" of sands, factors which undoubtedly served a useful purpose, but many engineers have endeavoured to apply them to concrete aggregates without obvious reason for so doing. It is apparent that these functions cannot be usefully applied to concrete aggregate since they are based on separations made by one or two sieve sizes and consequently are inadequate to show the value for concrete of aggregate which covers a wide range in size. A good idea may be gained of the wide range in sizes in concrete aggregate when we consider that the diameter of a 3-in. pebble is over 500 times that of a particle of sand which passes the 100-mesh sieve.

The work of Fuller and Thompson[3] is a source of valuable information. However, our experiments have shown that the grading given by Fuller in his "maximum-density curve" is too coarse for the ordinary mixtures; in other words, for the usual quantities of cement, the grading he suggests gives a harsh-working concrete. Another corollary of Fuller's method indicates that the aggregates should be separated into a number of sizes and recombined in order to approximate the so-called maximum-density curve. Our investigations show that the separation of aggregates into a number of different sizes followed by recombination is seldom, if ever, necessary or desirable; in addition, for fine aggregates this method involves great expense and many difficulties.

It was apparent at the beginning of our experimental work that a proper basis for proportioning concrete was not available; consequently, among our first investigations was a number of studies of the general subject of proportioning. The studies carried out so far, which deal with the many phases of proportioning concrete reach a total of about 100,000 tests, and are being continued. Capt. L. N. Edwards[4], Mr. R. B. Young[5], Prof. A. N. Talbot[6], Mr. F. L. Reman[7], and Prof. R. W. Crum[8], have furnished valuable information, so that we are able to approach the subject from many different angles.

EFFECT OF WATER ON THE STRENGTH OF CONCRETE

During our experimental work it soon became apparent that the quantity of mixing water used and the consequent consistency of the concrete was an important element in its final strength. A more comprehensive study of this phase of the subject has shown that the quantity of mixing water is by far the most important feature of the mixture; assuming, of course, that the concrete materials used are of good quality. The new feature of this relation is that the strength and other properties of the concrete are determined (other factors being equal) by the ratio of the quantity of water to the quantity of cement used in the batch, regardless of the reason for the change in the quantity of mixing water; that is, whether the quantity is changed because of variations in grading of the aggregates, change in the quantity of cement, or change in the consistency of the concrete (or any combination of these) so long as the concrete is plastic. This has given rise to a factor which we call "water-ratio" in dealing with concrete mixtures. This fundamental relation has been brought out by a great many different series of tests carried out in this Laboratory, and has been verified by many tests made by other laboratories. Concrete of the usual type has a water-ratio of about 0·75 to 0·90, depending on mix, grading of aggregates, and relative consistency of the concrete. The practical application of these principles lies in the fact that concrete of a given water-ratio has a constant strength (other factors being equal), consequently anything which tends to raise the water-ratio, such as wetter consistency or a finer aggregate, will reduce the strength. If a wet consistency or a fine aggregate *must be used*, the only way to restore the water-ratio to its proper value is to use more cement. Conversely we see that no advantage is secured from using more cement *unless* the water-ratio is lowered. The value of a coarse and well-graded aggregate lies in the fact that it can be mixed into a plastic concrete with a lower water-ratio than can a finer or poorly graded aggregate.

The mixing water in concrete serves two distinct purposes: (1) to supply the water necessary for the hydration of cement; and (2) to produce a plastic mixture. The exact quantity required for hydration has not been determined, but such information as we have indicates that it is a relatively small percentage as compared with the quantity which must be used in the concrete. Probably not more than a quarter or a third of the water that is usually placed in concrete is necessary for hydration.

The water-ratio is the factor which governs the strength and wearing resistance of the concrete. If we use one cb. ft. of water (about 7½ galls.) to each sack of cement, we would have a water-ratio of 1; a smaller quantity of water per sack would give a water-ratio of less than 1, etc. The usual water-ratio for ordinary conditions is about 0·8 or 0·9, or about 6 to 6¾ galls. per sack of cement. In dealing with water-ratio we disregard water absorbed by the aggregates, although water mechanically held by the aggregate would be considered. The use of more cement, improving the grading of the aggregate, or the use of different methods of finishing or placing concrete, in order that it may be placed with a lower quantity of mixing water—all of these things are simply means to an end; namely, to produce a plastic concrete with a lower water-ratio.

This brings us to a point which is generally overlooked in building codes and specifications. It seems to be a general opinion that the cure for all the difficulties of weak or inferior concrete is to increase the quantity of cement. However, if the addition of cement is not at the same time accompanied by a reduction in the water-ratio, it does not accomplish any useful purpose. The water-ratio may be altered owing to changes in the relations of the quantity of cement, grading of aggregate, or changes in relative consistency of the concrete; however, we arrive at the same result, indicating that it is the water-ratio which actually controls the strength and other properties of concrete.

GRADING OF AGGREGATES

Another important feature brought out by our early investigations was the general law which seems to govern the relation between the grading of aggregates and the quantity of water required for a concrete mixture and, indirectly, the strength of the concrete. This relation has given rise to the factor which is known as the "fineness modulus" of the aggregate—a simple function of the sieve analysis using a series of wire cloth sieves in which the size of clear opening is varied by multiples of 2. The following sieves recently recommended by the American Society of Testing Materials in their "Tentative Method for Sieve Analysis of Aggregates for Concrete," conform to this arrangement: No. 100, 50, 30, 16, 8, 4, ⅜ in., ¾ in. and 1½ in. The sum of the sieve analysis expressed in percentages of the material by weight or by volume *coarser* than the given sieves is the fineness modulus of the aggregate. A low fineness modulus corresponds to a fine aggregate and a high fineness modulus to a coarse aggregate. A concrete sand well graded up to ¼ in. has a fineness modulus of about 3·00 and a well-graded gravel or crushed rock from ¼ to 1½ in. in size has a fineness modulus of about 7·00. This factor is useful in dealing with various combinations of aggregates of different gradings.

It is not necessary, or desirable, that the aggregate be proportioned according to any fixed grading; wide variations in gradings may occur without affecting the quantity of mixing water or the quality of the concrete.

Theory of Concrete Mixtures

The real problem in proportioning concrete mixtures is to take advantage of the characteristics of the materials available and to produce from them a satisfactory concrete at a minimum cost. At present aggregate materials cannot be transported long distances; we may know ever so much about the ideal characteristics of sand and coarse aggregates, but we may not be able to get aggregates of ideal quality. In other words, we must make the best we can of the materials at hand.

Our investigations have led us to the following fundamental principles:—

1. The strength of a concrete mixture depends on the quantity of mixing water in the batch, expressed as a ratio to the volume of cement, *so long as the concrete is workable*, and the *aggregates are clean and structurally sound*. The strength of the concrete decreases as the water-ratio increases.
2. The effect of differences in the quantity of cement is reflected by differences in the water-ratio.
3. The sieve analysis of the aggregate is the basis on which proportioning must be done. There is an intimate relation between the size and grading of the aggregate and the quantity of water required to produce concrete of a given workability.
4. It is not necessary, or desirable, that the aggregate be proportioned according to any fixed grading; wide variations in gradings of aggregate may occur without affecting the quantity of mixing water or the quality of the concrete. The sieve analysis expresses the life history of the material, so far as its concrete-making properties are concerned. It is only necessary for us to interpret this information in order to use the material to the best advantage.
5. Plasticity or workability is an essential requirement of concrete for structural purposes.

Plasticity of Concrete

The question of plasticity or workability of concrete is a very important one. We could not use concrete at all if it were not for the fact that it can be mixed and placed while in a plastic condition. We must put in enough water to make our concrete plastic so that it can be worked into place. The question of a satisfactory method for controlling and measuring the plasticity of concrete is giving concrete engineers more concern to-day than probably any other one thing. A number of methods have been suggested and a great deal of experimental work is now under way. The method which probably has met with most common use, because of its simplicity, is the "slump" test, using a truncated cone form 4 in. in diameter at the top, 8 in. at the bottom and 12 in. in height. The shortening of the fresh concrete upon removal of the form is taken as a measure of the plasticity of the concrete.

There is a great need for constructive research in developing a satisfactory and practical method of determining the plasticity of concrete. Any method which is used for this purpose in the field should not be interpreted too strictly. If the specification indicates that the concrete should be mixed to a slump of 6 in., we would not be justified in rejecting a batch of concrete simply because it gave a slump of 7 in. The purpose of the test is to ensure that the concrete does not habitually go beyond the quantity fixed by the specification. If a slump test were made on the concrete as placed in most building construction, we would get a slump of 10 to 11 in. That is the type of concrete to guard against. A few engineers are still sceptical as to the practicability of such control; some may doubt whether an excess of water *does* produce an inferior concrete. In many cases the concrete produced on the job has a strength of probably not more than 20 to 30 per cent. of the strength it should have, and probably not more than 60 or 70 per cent. of the strength upon which the design was based. Under these conditions we should not be surprised to find inferior concrete, and we do find it too often.

Application of Principles of Proportioning

The foregoing principles lead us to a number of practical features of concrete-making.

The quantity of mixing water used to produce concrete of the condition of workability necessary is of major importance. Every care should be taken to restrict the mixing water to a minimum. An excess of mixing water produces the same result as omitting a large portion of the cement from the batch.

Methods have been developed whereby aggregates may be scientifically proportioned on the basis of sieve analysis without separation into a large number of sizes. Aggregates may be used with good results regardless of the fact that their grading does not conform to our older ideas. For example, the Iowa State Highway Department has embodied in its specifications for concrete roads a method whereby pit run gravels can be used in almost any proportions in which they occur, so long as they are clean, regardless of the fact that there may be a great excess of sand. Their method requires an increase in the quantity of cement in proportion to the quantity of sand in excess of a certain minimum. The specifications would permit the use of a mixture of cement and sand only, providing the cement content were increased to such an extent as to produce concrete of the strength and wearing resistance aimed at by the specification. The Illinois Division of Highways permits the same thing. This procedure would have been frowned upon a short time ago, but it has proven its value and will, no doubt, become general practice in the near future. The problem is to put together the aggregates available in order to get the best concrete we can for a given or a minimum cost.

Quality of Concrete

We have come to accept the compressive strength of concrete as a measure of other desirable qualities. The strength of concrete is an important factor in building and other types of construction; however, the quality of concrete has a wider bearing than mere strength. A structure which is exposed to the weather, with wide ranges of temperature, wide variations in moisture content, and probably exposed to other destructive agencies, must have a very considerable degree of resistance if it is to give a good account of itself, entirely apart from any load-carrying requirements. It is true, however, that the strength of concrete reflects to a very large degree its ability to withstand other destructive agencies. Our experiments have shown that, in respect of wearing[9] resistance, it is true that the strength is the proper measure of the quality. The flexural strength[10] of concrete is also influenced in the same general way as the compressive strength; tests and observation show that the resistance of concrete to attack of alkali, sea water, etc., is dependent on the same factors as those which govern the strength. We may say then that the compressive strength of concrete is an entirely satisfactory measure of its quality.

Tables of Quantities of Materials Required for Concrete

Based on the information secured from several thousand tests we have recently compiled a series of tables (*Bulletin* 9. Structural Materials Research Lab.), giving the proportions and quantities of materials required for concrete of strengths varying from 1500 to 4000 lb. per sq. in. at 28 days when tested in compression in 6 by 12 in. cylinders. Separate values have been worked out for mixtures of fine and coarse aggregates of different sizes and a wide range of consistencies as measured by the slump test. These tables will be found useful in estimating quantities of materials required for concrete of given materials and mixtures and also in estimating the probable strength of concrete and the relative strength of concrete of different mixtures, aggregates and consistencies.

Standard Tests of Concrete and Concrete Materials

During the past year or two the American Society for Testing Materials has published in its "Standards" and Proceedings the following *new* standards or tentative standards which are of interest to all concrete engineers.

1. Standard Method of Making and Storing Specimens of Concrete in the Field.
2. Tentative Method of Making Compression Tests of Concrete.
3. Tentative Specifications for Workability of Concrete for Concrete Pavements.
4. Tentative Method of Test for Sieve Analysis of Aggregate for Concrete.
5. Tentative Method of Test for Organic Impurities in Sands for Concrete.
6. Tentative Method of Securing Specimens of Hardened Concrete from the Structure.
7. Standard Method of Test for Unit Weight of Aggregate for Concrete.
8. Tentative Specifications for Concrete Aggregate.
9. Tentative Method of Test for Voids in Fine Aggregate for Concrete.
10. Tentative Specifications for Workability of Concrete for Concrete Pavements.

Those who have not looked up these standards recently will be well repaid for doing so. Many of the concrete tests made in the past are of little or no value, because sound principles of testing were violated. It is frequently impossible to interpret indications of concrete tests properly, on account of the lack of proper standard methods of manipulation. The tentative standard method for making tests of concrete should be consulted and followed so far as possible by all who have occasion to make tests. In those standards the details are given whereby consistent results can be secured in different laboratories and in different sections of the country, something we have not been able to do heretofore.

We have been floundering around for forty years, and for the first time we now have some semblance of a standard method for making sieve analysis of aggregates. Heretofore practically every laboratory used a different set of sieves or used a different method of recording sieve analyses, and consequently the results have been so divergent that it has been almost impossible for one person to make anything out of the work done by others; standard sieves and methods are very important steps in advance. Considerable progress is being made in many directions in the improvement and standardisation of concrete tests, all of which will exert an important influence on the quality of work, and will in the near future result in a higher average of good concrete.

SOME RECENT WORK ON THE FATTY ACIDS

By T. W. JONES, B.Sc.

The higher fatty acids figure among the substances most recently investigated by means of the X-ray spectra. Since Laue's brilliantly successful experiments in 1912 the application of X-rays to the elucidation of the structure of solid bodies has resulted in a continuous increase and extension of our knowledge of the latter. As is well-known, Laue's work had for its object the measurement of the wave length of the X-rays. The interatomic spacing of the crystal being known to be of the order of 10^{-8} cm., he used the crystal as a diffraction grating and so obtained, on an ordinary photographic plate, a spectrum somewhat similar to that of optical light. From the spectra the wave length of the X-rays was calculated to vary between the orders 10^{-8} cm. and 10^{-9} cm.

Having unlocked the door to the elucidation of crystal structure he passed on, leaving to others the task of opening it. Foremost among those to take up this work and reveal to us that the external symmetry of the crystal is an outward and visible sign of an internal regularity of arrangement of its atoms were Sir W. Bragg and his son, Prof. Bragg. They showed us that the crystal may be regarded as a series of planes parallel to its face, each plane being packed with molecules the atoms of which are arranged in the form of a space lattice; and that each plane is equidistant from its neighbour, this distance being the "spacing" of the crystal. As might be expected, Laue's methods had to undergo many alterations and elaborations, from which was finally evolved the X-ray spectrometer. This instrument, now in almost general use, allows X-rays from the anticathode of an X-ray bulb, constricted by lead slits to a narrow pencil, to impinge on the crystal, or mass of powdered crystals, mounted at the axis of a rotating arm; the reflected rays, both incident and diffracted, are then photographed on an ordinary photographic plate or film. By rotating the arm a continuous band spectrum is obtained, in place of the discontinuous spectrum of concentric rings of dots obtained by Laue. A further elaboration of the method is to receive the rays from the crystal in an ionisation chamber, containing a heavy gas, such as sulphur dioxide, ionisation of which is recorded on a gold-leaf electroscope. From measurements obtained by these means the internal arrangement of the atoms and molecules of a large number of crystals has been calculated.

It would seem but a step from the application of X-rays to crystals, to their application to the discovery of the internal composition of other solids. This step, however, has been somewhat difficult to take until just recently, by reason of the paucity of our knowledge of the physical structure of these bodies. Particularly were we ignorant of those substances, which are neither crystal nor liquid, and called, for want of a better name, liquid crystals. Recent work by G. Friedel, however, has so far enlightened our knowledge of these substances as to enable us to utilise the X-rays to reveal their structure. In a paper published early this year he postulated that matter is capable of existing in two forms, distinguishable by their structure, and neither crystalline nor liquid, to which he applies the term "meso-morphic state." The first form he calls the smectic phase, so named after the soaps which are included in it, and the second the nematic phase on account of the linear discontinuities which constitute its chief feature. The smectic phase is optically positive, possesses high viscosity and is quite rigid, except in the direction of its optical axis, displacement being invariably accompanied by change of structure. Friedel is of the opinion that the smectic bodies consist of a regular formation of equidistant molecular layers, and hence they should be able to diffract the X-rays in a manner similar to that displayed by the reticular parallel planes of a crystal system.

Since this paper appeared the result of work on some of the smectic bodies, the alkali salts of oleic acid, has been published by De Broglie and Friedel in the *Comptes Rendus*. Taking into consideration the fact that the chemical formulæ of these substances always contain a long rectilinear CH_2-chain, and that these chains were probably arranged parallel to the optical axis, it seemed probable that the distance between two homologous points of two successive layers, *i.e.*, the spacing, would be at least equal to the length of these chains and large compared with the atomic distances. They therefore decided to employ X-rays of a longer wave length than would be used for work on crystal structure. The X-ray spectra so resulting were consistent with a spacing of about 40 Angstrom units, which would seem to confirm the correctness of Friedel's original opinions regarding the molecular construction of the bodies.

Experiments on a series of homologous fatty acids have also been carried out by Muller in a similar manner to that adopted by De Broglie and Friedel. The acids investigated were the more common ones, capric, lauric, myristic, palmitic, and stearic, a series showing increasing length of the CH_2-chain. It was found that the spacing increased with increase of the length of the CH_2-chain, thus providing still further confirmation of Friedel's theory.

The method adopted was to melt a little of the pure acid on a glass plate and spread it out in a thin film 2-3 mm. wide, 1 cm. long, and 0·1 to 0·2 mm. thick, the acid then crystallising in flakes which oriented themselves parallel to the surface of the glass. The plate was fixed in the crystal holder of an X-ray spectrometer, and oscillated, this giving a spectrum consisting of lines on each side of the reflection of the primary beam, so eliminating any errors which would result from using the latter as the zero line. The photographs show well-defined lines and the distances between corresponding lines vary for the different acids, decreasing as the length of the CH_2-chain increases. The photographs show, in addition to these characteristic lines, two other lines which appear constant for all the acids.

From these data it is assumed there is a possibility that the unit cell of the fatty acid may be in the shape of a long prism of the same cross-section for all the acids, the length of the prism increasing proportionately to the number of CH_2 groups in the molecule.

Only future events can demonstrate the truth of this hypothesis, but some proof is afforded of the increase of spacing corresponding with an increase in the length of the CH_2-chain in papers by N. K. Adams in the *Proceedings* of the Royal Society for last year, where it was deduced from measurements of thin films of these acids on the surface of liquids, in which they were insoluble, that the molecules arranged themselves in parallel cells and that the spacings increased with increase in length of the CH_2-chains.

THE PRINCIPLES OF BOILER FEED WATER TREATMENT

There is ample room for a short treatise giving in clear and concise language the essential scientific principles underlying the hardness of water and the methods to be adopted for the prevention of scale and corrosion in boilers. Such a publication (pp. 32), has just been issued by Messrs. Brunner Mond and Co., Ltd., having been written by their research staff, and may be obtained free of charge from the company at Northwich, Cheshire. The detailed explanation of the soda ash and lime method of treatment, together with the selection and method of working of the necessary plant, is particularly good. The great advantage of this method, the old Porter-Clark process with the addition of suitable mechanism to facilitate the quick separation of the precipitated calcium carbonate, is that not only does it separate practically all the objectionable scale formed and corrosive material outside the boiler, and deliver clear water only, but that no soluble salts are added to the water. Substances such as sodium sulphate and other neutral salts are in themselves harmless, but when they accumulate in the boiler they give rise in practice to all kinds of difficulties, tending to cause, for example, electrolytic action and heavy priming, besides impregnating the steam and affecting the jointing material.

The proper scientific method is to take everything out of the water before it goes into the boiler, and whilst one may, perhaps, not altogether agree with the statement (p. 25) that the soda ash and lime treatment will give a final water as low as 3° hardness, at any rate 5° can certainly be obtained without difficulty by anyone who has a reasonable knowledge of the process. The book should prove invaluable in showing how results of this kind may be obtained all the year round, and also in dealing with the more difficult aspects of the question, such as the removal of the last traces of magnesium, and the presence of oil, carbonic acid, carbonates, and acids, both mineral and organic.

LOW TEMPERATURE CARBONISATION

Coalite Developments at Barnsley

The well-known "Coalite" plant at Barugh, near Barnsley, which has been in practically continuous operation since the latter part of 1921, is now to be greatly extended so as to be capable of carbonising 500 tons of coal per 24 hours. It is claimed that the very difficult practical problems of the low temperature carbonisation of coal have now been finally solved with the present form of plant, but Messrs. Low Temperature Carbonisation, Ltd., have desired to give the matter a thorough large-scale practical test of long duration. Hence the two years' run, and it may be stated also that the plant in operation at Barnsley has been visited by a large number of chemists, fuel technologists, engineers, and other experts, not only from all over Great Britain, but also from foreign countries as well. The results are stated to have been so successful that the present great extensions are now to be proceeded with immediately, and it is also the intention to erect similar 500-ton plants in different industrial centres so as to supply the local demand for smokeless fuel, motor spirit, liquid fuel and sulphate of ammonia. As will be remembered, the "Coalite" process consists in the direct carbonisation of coal, without any preliminary treatment or subsequent briquetting, at 1000° F., and that the yield from one ton of ordinary average semi-bituminous coal, with 25—30 per cent. volatile matter, is 4500—6000 cb. ft. of very rich gas (700—825 B.Th.U.), 18–20 gallons of valuable paraffinoid low temperature oils, 15 lbs. of sulphate of ammonia, and 14 cwts. of residual smokeless "Coalite" containing 10 per cent. volatile matter, which is, of course, absolutely smokeless for this reason.

Of course the yield differs, depending on the coal, and some recent lengthy experiments, for example, carried out over many months showed that 8280 tons of coal gave a yield of 6210 tons of smokeless coalite, 172,565 gallons of tar oils, and over 38,000,000 cb. ft. of rich gas, over 800 B.Th.U. and there seems to be no question that the problems are now finally solved.

The work that has been involved in this achievement is almost incredible, dating back to Parker's first experiments at Wednesfield, near Wolverhampton, in 1901, and the total cost is stated to have been over £1,000,000, whilst the amount of coal carbonised is over 100,000 tons. The chief trouble, of course, is one of price, and especially the value to be placed on the "Coalite." It is agreed that a smokeless fuel of this nature burns in an open grate with a very high radiant efficiency, something like 30—35 per cent. as against 20 per cent. for coal, but it is obvious the householder will never pay anything like its true value. However, it is stated that "Coalite" can be put on the market at the same price as raw coal and still leave a reasonable margin, and if this is the case the success of low temperature carbonisation should be assured.

FORTHCOMING EVENTS.

Nov. 16. Chemical Engineering Group at the Chemical Industry Club, 2, Whitehall Court, London, S.W. 1, at 8 p.m. "A New Source of Potash and its Industrial Exploitation," by Prof. J. W. Hinchley.

Nov. 19. Society of Chemical Industry, *Yorkshire Section*, the Queen's Hotel, Leeds, at 7.15 p.m. "The Work of the Chemist in Connexion with the Textile Industries," by Dr. Lloyd.

Nov. 21. Society of Chemical Industry, *Nottingham Section*, the University College, Nottingham, at 7.30 p.m. "Observations on certain Micro-organisms growing in Glycerol," by H. S. Holden and J. E. I. Gilbert. "Organic Compounds of Tin," by H. Lambourne. "Demonstration of a Universal Regulator of Acidity, with some suggested Uses in Analysis," by Dr. E. B. R. Prideaux.

Nov. 19. The Institution of Rubber Industry, Midland Hotel, Manchester, at 7.30 p.m. "Costing in the Rubber Industry as an Essential Factor to Successful Production," by C. A. Fryer.

Nov. 21. Royal Microsopical Society, 20, Hanover Square, W. 1, at 7.30 p.m. "Exhibition of Bacteriomorphic Granules Resulting from Cell-lysis or Digestion," by Dr. H. M. Woodcock.

Nov. 21. Society of Glass Technology, Lecture Room of the Coal, Gas, and Fuel Industrial Department, The University, Leeds, in the afternoon.

Nov. 21. Institution of Electrical Engineers, *Wireless Section*, Savoy Street, Victoria Embankment, London, W.C. 2, at 6 p.m. "Periodic Trigger Reception," by E. V. Appleton and F. S. Thompson. "A Dynamic Model of a Valve and Oscillating Circuit," by R. C. Clinker.

Nov. 23. The Institution of Mechanical Engineers, Storey's Gate, London, S.W. 1, at 7 p.m. Informal Meeting.

Nov. 23. Society of Chemical Industry, *Manchester Section*. Annual Dinner at the Queen's Hotel, Manchester.

Nov. 23. West of Scotland Iron and Steel Institute, Royal Technical College, George Street, Glasgow, at 7 p.m. "Effects of Time and Temperature on High Speed and Similar Steels," by W. E. Woodward.

Nov. 23. The University of London, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science," by Prof. G. Dawes Hicks. (Lecture 4.)

Nov. 23. Society of Chemical Industry, *Glasgow Section*, The Engineers' and Shipbuilders' Institute, 39, Elmbank Crescent, at 7.15 p.m. "Artificial Resins—their Preparations and Uses," by H. Hepworth, D.Sc.

Nov. 26. The Faraday Society. General Discussion on "Electrode Reactions and Equilibria," at the Institution of Electrical Engineers, Victoria Embankment, from 3 to 7.30 p.m.

Nov. 26. Birmingham University Chemical Society, Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "Chemical Theories of Atomic Structure," by C. J. A. Taylor, B.Sc.

Nov. 26. Chemical Industry Club. Annual Dinner at the Connaught Rooms, Great Queen Street, W.C. 2, at 7 for 7.30 p.m.

Nov. 27. The University of London, W.C. 1, at 5.30 p.m. "The Pan-Pacific Congress," by W. J. Perry.

Nov. 28. Royal Institute of Public Health, 37, Russell Square, W.C. 1, at 4 p.m. "Problems in Relation to Health in the Tropics" (with lantern illustrations), by Miss K. Platt, M.D.

Nov. 28. Royal Microscopical Society, *The Industrial Applications Section*, 20, Hanover Square, W. 1, at 7.30 p.m. "The Characteristics of a Microscope for General and Special Purposes," by J. E. Barnard, F.Inst.P.; "The Application of the Microscope to Industrial Diseases," by Dr. S. H. Browning, L.R.C.P.

Nov. 28. Royal Society of Arts, John Street, Adelphi, W.C. 2. "The Effect of Sun, Sea, and Open-air in the Treatment of Disease," by Sir H. J. Gauvain, M.A., M.D., at 8 p.m.

Nov. 29. Institution of Mechanical Engineers, The Medical Theatre, University, Edmund Street, Birmingham. "Metal Rolling and the Influence of Cooling on Plastic Flow," by J. E. Fletcher.

Nov. 29. Institution of Mechanical Engineers, Engineers' Club, Albert Square, Manchester. Further discussion on "Clyde Marine Oil-Engines," by Prof. A. L. Mellanby.

SOCIETY OF CHEMICAL INDUSTRY

SOUTH WALES SECTION

A meeting was held in Cardiff on November 8. The formal meeting was preceded by a dinner, at which the chairman, Capt. Hugh Vivian, presided, the guests including Dr. E. F. Armstrong, F.R.S., the President, the Lord Mayor of Cardiff, Principal Trow of the University College, Mr. William Johnson, President, and Mr. Martin Price, Secretary of the South Wales Institute of Engineers, and Principal Coles of the Technical College.

The loyal toast having been honoured, the chairman proposed the health of the President, Dr. Armstrong, referring to his eminence in the realm of pure science as well as in industry, and expressing the thanks of the section to him for his visit to South Wales. Mr. W. R. Bird (vice-chairman) proposed a toast to the hon. secretary, Dr. H. E. Cox, expressing the regret of the committee and of the members that he had to resign this office on account of his removal to London. Mr. G. R. Thompson seconded. The members and guests then adjourned to the South Wales Institute of Engineers (whose theatre was kindly lent by the Council of that Institution), where, after a brief introduction by Capt. Vivian, Dr. E. F. Armstrong delivered an address on "The New Chemistry."

Dr. Armstrong said that it can be argued that we have just entered on a new stage in chemical investigation. Labours in the main of an analytical type have enabled the exact structure of all but a very few substances to be established; the results have been confirmed by synthetic operations, and most compounds have been built up step by step from their elements. Whilst the modern school of physicists by a series of most brilliant researches has learned much about the nature of the atom, the chemist is now concerned with the behaviour of the molecule. This has entailed the recognition that he has not only to deal with crystals and relatively simple molecules in solution, but also to consider actions taking place at the surface of colloid aggregates. As it is probable that the bulk of the reactions in the plant and animal cell are of this nature their importance will be at once conceded. Further, it must be realised that there is evidence that molecules in solution have a definite space orientation at such colloid surfaces and indeed, according to the work of Hardy, at surfaces in general.

According to the accepted space lattice theory of matter, there is a definite attraction causing adhesion between each layer of molecules and consequently at a surface, say, of a piece of glass there are unsatisfied forces of valencies. At first when a drop of a lubricant is placed on such a surface nothing happens, but when two surfaces of glass are moved over one another the molecules of the lubricant become arranged according to a definite pattern. The chemist to-day in seeking to explain chemical action has to realise that this takes place in many instances between aggregates of molecules and at the surface of such aggregates and not between single simple molecules in solution such as his equations postulate and the ionic theory in its original form demands.

The first fact which has emerged from the detailed study of chemical action at a surface is that the action is not one of the so-called first order in which the same fraction of the reacting substance undergoes changes in successive equal intervals of time—a change expressed graphically by a logarithmic curve. When proper and sufficient care is taken to keep the surface active the rate of change is uniform, provided that the changing substance is present at the surface in sufficient quantity. These facts are in accord with the hypothesis that action is preceded by the formation of an additive unstable complex which breaks down in all possible ways, that is, into a variety of components practically as fast as it is formed. The problem of the source of the energy necessary to effect this is not without interest, but it is common to all chemical reactions and its discussion may safely be left to the exponents of the quantum and other theories.

Such actions as we are considering are known as catalytic, the change being effected by virtue of the activity of the catalyst surface, the only other agent involved in practically all cases both in the living cell and the test tube being water. It is now recognised that the water molecule can undergo rupture in two ways, either being distributed upon a single molecule, which is thereby resolved into two others

$$A.O.B. + H.OH = A.OH + B.OH$$

or divided between two molecules in such manner that whilst the one is oxidised the other is reduced—

$$A + 2\,H{\cdot}OH + B = AO + H_2O + BH_2.$$

Entirely different classes of catalysts bring about the two actions, but all are classed as enzymes when concerned with changes which take place in the cell. Such enzymes as are well known are highly specific and selective, a different enzyme being required for each class of compound.

Armed with the knowledge of the fundamentals of chemical action in the cell, the time is ripe for the chemist to ascertain the inner meaning of phenomena which the biologist can only investigate by the recording of external visual characteristics. As a case in point, the coloration of flowers and its inheritance may be cited. There is much in favour of the view that flower colours, whether anthocyans or belonging to other groups, are the product of the interaction of two factors, an oxidase and a colourless precursor of the pigment. The absence of either factor means failure to develop colour by the plant, *i.e.*, white flowers, and there may also be a third factor present which prevents action taking place between oxidase and leucobase.

If proper combination of effort between the biologist and chemist can be ensured, very many baffling problems, many of which are of far-reaching economic importance, can be attacked.

A hearty vote of thanks was proposed by Mr. Bird and seconded by Professor C. M. Thompson.

LONDON SECTION

At the first meeting of the session on November 5, Dr. Monier-Williams, the hon. secretary, gave an account of experience gained during the past two years in the fumigation of ships for the purpose of destroying rats and vermin with hydrogen cyanide. He pointed out that poisoning and trapping can never account for the whole of the rats on a ship, whereas fumigating, if properly carried out, can do so. In the past, sulphur dioxide has largely been used, but as the United States quarantine regulations of 1920 require all vessels engaged in trade with foreign ports to be fumigated every six months, it became necessary to fumigate the passenger quarters of trans-Atlantic liners, for which purpose sulphur dioxide cannot be used owing to its corrosive action on furnishings and decorations.

Hydrogen cyanide was first used in 1890 in the orange orchards of California and Florida; in 1898 it was used by the Cape Government railways for bugs and lice in sleeping carriages; it was used in India by Col. Glen-Lister in 1899 and in quarantine work at Porto Rico in 1910. Since the war, the use of hydrogen cyanide has become general, especially in American, Australian and Italian ports. Until last year, however, it was used on a comparatively small scale and only recently, owing to the United States quarantine regulations, has the complete fumigation of large passenger vessels been attempted. As a consequence, the use of hydrogen cyanide was decided upon by the Cunard and White Star companies, and Dr. Stock and Dr. Monier-Williams were deputed to watch the experiments on behalf of the Ministry of Health.

The toxicity of hydrogen cyanide is not so great as was formerly imagined, and possibly 1 part in 10,000 of air, or even a higher concentration, can be breathed with impunity. At the same time, beyond 1 part in 2000 of air, its action is rapid, and 1 in 500 would probably kill a man instantly. It is not an irritant, however; it has not much smell; and the critical point is not easy to recognise. Thus the precautions necessary are more elaborate than with sulphur dioxide, and it is essential when fumigating by this method to organise the work most carefully.

The various methods of using hydrogen cyanide were then described, the simplest being to place tubs in various parts of the ship containing 1½ parts by weight of sulphuric acid to 1 part of water, and to hinge, on the sides of the tubs, boxes containing solid cyanide, these boxes being tipped up by means of a cord so that their contents fall into the tubs and so cause liberation of the gas. Accidents have occurred in foreign ports by the use of hydrogen cyanide, but Dr. Monier-Williams is of opinion that these have mostly occurred through negligence in adopting the most ordinary precautions.

Among the other methods mentioned was a solution method in which the cyanide was previously dissolved in water and the solution poured through funnels on deck through rubber hose pipes leading to the tubs below, and on the whole it was suggested that this was the most preferable. Many investigations are required, however, before the fullest information can be available with regard to the use of hydrogen cyanide for fumigation. We know practically nothing about the rate of mixing of gases in a ship, nor do we know at how many points should gas be liberated, whether artificial circulation of air should be effected, how far hydrogen cyanide is liable to form pockets and so be a danger afterwards, and how far it is absorbed by walls and different materials and given off subsequently. The only way to obtain reliable information is by thorough sampling of the gas and the vacuum bottle was suggested as the best method of doing this.

After stating that fumigation by hydrogen cyanide is cheaper than sulphur dioxide, Dr. Monier-Williams said that if the former was to be adopted generally, the problems which he had suggested must be tackled with the view of carrying out the operation in the most effective way at a minimum expense.

During the discussion various suggestions were made for the use of other substances such as chlorine and carbon monoxide. It was also mentioned that the greatest expense connected with the complete fumigation of ships was the enormous amount of labour involved on large vessels like the *Berengaria* or *Mauretania*.

MANCHESTER SECTION

In the announcement of the forthcoming papers to be read before the Manchester Section there is one by Knecht and Muller on "The dehydration of alcohol." In consequence of the appearance of two recent papers, the first by W. B. S. Bishop, on "Ethyl formiate from oxalic acid, glycerol and ethyl alcohol" (This *J.*, 1923, 401 T), and the second by R. Wright on

"Selective solvent action by the constituents of aqueous alcohol" (*J.C.S.*, 123 & 124, 2493), the authors have decided to communicate briefly the essential point in their forthcoming paper, which consists in the employment of anhydrous glycerin as a convenient means for the dehydration of alcohol. In its simplest form the process consists in adding to commercial alcohol (*e.g.*, P.B.S.) about a quarter of its weight of pure glycerin and distilling the mixture from a water bath, the distillate being collected up to 80° C. (bulb in vapour). Details and modifications of the process, as well as analytical data, are given in the paper.

NEWCASTLE SECTION

At the opening meeting of the Session, held on October 31 in Armstrong College, Mr. A. Trobridge presiding, Mr. H. R. Whitehead, M.Sc., read a paper on "Milk."

The opening part of the paper dealt with the necessity of a pure milk supply, and described the chemical constituents of milk in some detail, as well as the various methods adopted for the estimation of its constituents.

The question of bacteriological contamination was treated at length, and the fact that milk is almost an ideal medium for the growth of bacteria was utilised to show how necessary it is to keep the milk at a low temperature and to prevent contamination by bacteria. The fallacy of the so-called dirt test was emphasised, and it was pointed out that the amount of dirt found bore no relation to the number or kind of bacteria present and was no criterion of cleanliness. A description was given of the usual kinds of bacteria which were found in milk, and the regulations issued by the Government regarding graded milk and the methods of carrying out the tests specified were discussed.

BRISTOL SECTION

The second ordinary meeting of the Session was held in the Chemical Theatre of the University on November 1, when Mr. A. H. Bridges read a paper entitled, "Some aspects of the paint trade—fine colour and lake making." The audience numbered 78, and included members of the Bristol Printers' Managers' and Overseers' Association, who were present by invitation. Mr. M. W. Jones occupied the chair.

The author touched briefly upon the universal use of colour for personal and decorative ornament from the earliest times, pointing out how the development of the coal-tar dyestuff industry furnished the colour-maker with shades hitherto unattainable and gave rise to a large and interesting branch of chemical industry.

In discussing chromate of lead colours, the lecturer set forth how the various shades and qualities were produced, demonstrating by formulæ and experiments the differences between them. Passing on to Cyanogen Blues, an account was given of the manufacture of the various trade types—Prussian, Pure and Chinese, and the characteristics of each. Pure and Brunswick Greens, made by blending Chrome Yellow and Cyanogen Blue in various proportions were next touched upon, and it was shown how lakes and fine colours were prepared by precipitating one or more of the coal-tar dyestuffs upon a suitable base, the nature of which frequently affected the ultimate shade.

The plant and routine of a colour works was fully described, the uses to which the finished colours are put were elaborated, and it was shown how these products of the colour-maker are passed on to enrich paints and colour distempers, to print or stain wall-papers, floorcloth and linoleum, to produce printing inks either for paper or metallic surfaces, and for the decoration of motor-cars and carriages.

The paper was illustrated by numerous experiments, lantern slides and samples, and gave rise to an interesting discussion, after which the meeting terminated with a vote of thanks to the lecturer.

BIRMINGHAM AND MIDLAND SECTION

A meeting was held on November 6 in the University Buildings, under the scheme of co-operation with the Chemical Society. Summaries of the papers are appended.

The aminoacetophenones as colour intermediates, by Prof. G. T. Morgan, F.R.S., and J. E. Moss, M.Sc.

The nitration of acetophenone furnishes an interesting illustration of the Crum Brown rule of substitution among aromatic compounds, the main product being *m*-nitroacetophenone, accompanied by *o*-nitroacetophenone as by-product. Although the yield of the latter increases with rise of temperature, meta-substitution of the nitro-group remains a predominant factor, but owing to oxidation a considerable portion of the meta-derivative appears in the form of *m*-nitrobenzoic acid. The ortho,- meta- and para-aminoacetophenones, when diazotised and coupled with β-naphtholsulphonic acids, do not behave as mordant dyes, although this property is developed when *o*-aminoacetophenone is replaced by anthranilic acid.

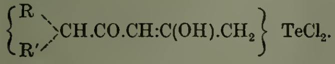
The bactericidal action of tellurium derivatives of aliphatic β-diketones, by Prof. G. T. Morgan, E. A. Cooper, and A. W. Burtt.

The action of the tellurium derivatives of aliphatic β-diketones of the general formula, $R.C_5H_6O_2{:}Te$ have been studied on *B.typhosus*, *Staphylococcus py.aureus* and other micro-organisms. The carbolic acid co-efficient is shown to vary considerably with alterations in the chemical structure of the β-diketonic group.

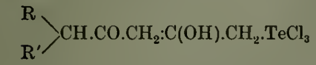
Interaction of tellurium tetrachloride and the higher β-diketones. Parts I., II. and III. Prof. G. T. Morgan, H. D. K. Drew, E. Holmes and R. W. Thomason.

The interaction of tellurium tetrachloride and the homologues of acetylacetone is influenced in a remarkable degree by the chemical structure of the β-diketones. When the carbon chain is unbranched two hydrogens are substituted in the diketone, giving rise to dichlorotellurium derivatives of the general formula $R{\cdot}C_5H_6O_2''TeCl_2$; these dichlorides on reduction give rise to well-defined tellurium derivatives $R.C_5H_6O_2Te$, appreciably soluble in water, which have a marked bactericidal action on various pathogenic organisms.

When the carbon chain is branched the condensation leads to tellurium derivatives of the type :—

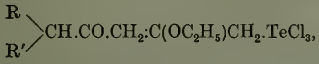


$$\left\{ \begin{matrix} R \\ R' \end{matrix} \!>\! CH.CO.CH{:}C(OH).CH_2 \right\} TeCl_2.$$



$$\begin{matrix} R \\ R' \end{matrix} \!>\! CH.CO.CH_2{:}C(OH).CH_2.TeCl_3$$

and



$$\begin{matrix} R \\ R' \end{matrix} \!>\! CH.CO.CH_2{:}C(OC_2H_5)CH_2.TeCl_3,$$

the last of these arising from the intervention of ethyl alcohol present in the chloroform employed as the organic solvent. β-Diketones of more complicated type, such as diacetylacetone and dimethylhydroresorcinol react quite differently, giving rise to oxonium tellurichlorides.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

At the meeting held on October 29, Mr. F. J. Corby, B.Sc., read a paper on " Perfumes." After a brief description of the natural perfumes, the general types of compounds used in the perfumery trade were described, and an account was given of the various processes employed in extracting plant perfumes, including those of distillation, expression, enfleurage, maceration and extraction with volatile solvents. The process of " fixation " was outlined, together with a short account of musk and ambergris and a more detailed account of such perfumes as jasmin, violet, rose and lily, illustrated the uses of various synthetics and natural products in the manufacture of scents. The latter part of the lecture was devoted to specific examples such as eau-de-cologne and lavender water, and a comparison of the old and modern recipes for various scents. The lecture was amply illustrated by slides showing the various cultivated areas mentioned, and a large number of samples of raw materials and finished products was exhibited.

CHEMICAL SOCIETY

MEMORIAL LECTURE, NOVEMBER 8th, 1923

Dr. J. H. Jeans, Secretary of the Royal Society, delivered the Van der Waals Memorial Lecture to a large company of Fellows and visitors in the lecture hall of the Institution of Mechanical Engineers, the President, Prof. W. P. Wynne, F.R.S., occupying the chair.

Referring briefly to the career of the distinguished Dutch physicist, a self-made man whose eminence was illustrated by the fact that even his doctorate thesis was a classic, the lecturer pointed out that he was the pioneer in that field of physics and chemistry which still characterised research in Holland.

Van der Waals' equation :—

$$\left(p+\frac{a}{v^2}\right)(v-b)=\alpha T$$

expresses the result of supposing a molecule to be endowed with two distinct physical properties—finite size, giving rise to the term b, and cohesive force, giving rise to the term a/v^2. The physical meaning of the equation is best exhibited by drawing diagrams of isothermals of the familiar type. Representing different gases there will be different diagrams corresponding to different values of a and b. It is, however, readily shown that one diagram of this type can be made to represent all values of a and b, and so the isothermals of all gases, by suitable expansions and contractions of its horizontal and vertical scales. On removing the scale from any single diagram we have a universal diagram which represents the p.v.T relation for all gases, but without specifying the scale. The circumstance that such a diagram is possible is equivalent to the so-called " Law of Corresponding States " : this is now seen to be a mathematical consequence of Van der Waals having confined himself to a two-constant specification of molecular structure.

Thus the accuracy, or the reverse, of the law of corresponding states provides a test of the sufficiency of Van der Waals' two-constant specification of a molecule. In actual fact the law is not very closely obeyed, and the deviations show distinct correlation with atomicity and so suggest that the two-constant specification is not altogether adequate—a full treatment must take account of differences of atomicity (or physical shape) as well as of differences of size and cohesive power.

Van der Waals explained his cohesive power by the supposition that all matter possesses inherent powers of attraction for all other matter. Gravitational attraction is numerically far too small to come into the question at all, so that it is to the electrical structure of matter that we must look for the origin of this supposed universal attraction.

If molecules were electrically charged structures, similar molecules would repel one another; as they are electrically neutral, they will repel in some orientations and attract in others, but two molecules meeting at random are as likely to repel as to attract. It is only when we study the *duration* of molecular encounters that we find an explanation of the preponderance of attraction over repulsion—attractive encounters draw the molecules further and further into each other's sphere of influence, and so last longer than repulsive encounters. Comparing the two types of encounters, the "birth rate" is the same for each, but the "expectation of life" is longer for attractive encounters, so that for the encounters in being at a specified instant, there is a preponderance of attractive encounters, and hence a resultant attractive force. This attractive force, however, originates far more in an abstruse theorem of statistical mechanics and far less in an inherent property of matter, than Van der Waals supposed.

If this interpretation is right the cohesive forces must disappear at very high temperatures and must steadily increase with decreasing temperatures, so that a must be a function of the temperature and not, as Van der Waals supposed, a constant. In point of fact, all attempts to bring Van der Waals' equation into closer agreement with observation begin by making a a function of the temperature. Moreover, a is found to vanish at infinite temperatures in conformity with the suggested explanation.

The second constant b was supposed by Van der Waals to have its origin in the finite sizes of the molecules. If, for instance, the hydrogen molecule is regarded as a sphere, its radius as calculated from the observed value of b is found to be $0{\cdot}64 \times 10^{-8}$ cm. The same radius can be calculated independently in other ways; the coefficients of viscosity, of conduction of heat and of self-diffusion all agree in yielding the value $0{\cdot}68 \times 10^{-8}$ cm. The average of these, $0{\cdot}66 \times 10^{-8}$ cm. would give for the hydrogen *atom* a volume equal to that of a sphere of radius $0{\cdot}53 \times 10^{-8}$ cm. But the normal hydrogen atom, as we now know from the researches of Bohr, consists of two electric charges, describing a circular orbit, one about the other, of radius precisely equal to $0{\cdot}53 \times 10^{-8}$ cm. As regards collisions with other molecules, this invertebrate structure consisting of two point-charges with no material connexion between them appears to reserve for itself a three-dimensional spherical volume with as much precision as though it were a sphere of infinite hardness.

The explanation of this infinite hardness is to be found in the intangible fetters of the quantum dynamics. The nature of these fetters we do not in the least understand, but we believe that they are such that no force in creation can cause the electron of the hydrogen atom to describe a smaller orbit than the normal orbit of radius $0{\cdot}53 \times 10^{-8}$ cm. If we further suppose that this orbit is free to assume all orientations in space we at once understand why it is legitimate, for kinetic theory purposes, to treat the hydrogen atom as an infinitely hard sphere of radius $0{\cdot}53 \times 10^{-8}$ cm. The quantum-theory brings us back, in a sense, to the infinitely hard spherical atoms of Lucretius, and the radius of these spherical atoms can now be calculated with precision from the quantum theory; their infinite hardness is beautifully exemplified in the experiments of Franck and Hertz.

We thus see that the a and b of Van der Waals admit of exact interpretation in terms of the physical conceptions of to-day. His b arises from what we may call the quantum forces—the perfectly unyielding restraints which bind the electrons of an atom down to definite orbits—while his a arises from the ordinary electric field of force. It is the b of Van der Waals which saves us from immediate annihilation, through positive and negative charges rushing together to their mutual destruction, just as it is his a which saves us from rapid disintegration.

Prof. F. G. Donnan, F.R.S., in proposing a vote of thanks to the distinguished mathematical physicist to whose brilliant exposition they had listened, remarked upon the continuance in Holland of the investigations into the states of matter which had begun with Van der Waals' work; and this in turn had been largely a mathematical interpretation of the experiments of Thomas Andrews.

Dr. N. V. Sidgwick, F.R.S., seconded, alluding to the exceptional lucidity of the treatment which they had had the privilege of hearing.

SOCIETY OF PUBLIC ANALYSTS

Mr. P. A. Richards presided over the meeting held in the Rooms of the Chemical Society on November 7, when three papers were presented:—

(1) "The Gold-Beaters' Skin Test for Tannins," by Phyllis H. Price, B.Sc. In tanning the tannins are fixed by animal fibre. A reliable tannin test must therefore demonstrate this specific property, and such a test has been described (*Biochem. Jour.*, 1922, 16, 516), the method consisting in fixing the tannin on gold-beater's skin and subsequently staining the skin with ferric chloride. Non-tannins are not fixed on the gold-beater's skin, which consequently, is not stained. The author has further developed the test and finds that it is possible to detect 0·00005 g. of gallotannin in 1 c.c. of solution with the use of either ferrous sulphate, ferrous chloride or amyl nitrite fumes in place of ferric chloride. It was also noticed that on decolorisation with dilute hydrochloric acid skins previously treated with pyrogallol tannins are completely decolorised, whereas

those treated with catechol tannins have a reddish stain left on them. This is suggested as a test for phlobaphenes.

(2) "Determination of Nitrogen in Coal," by W. Donovan, M.Sc. The author confirms the work of Fieldner and Taylor, Terres, Fleischer and others, who observed that the Dumas process as described in the report of Research Committee of the Institute of Gas Engineers, and the Kjeldahl method, both gave results below truth, the former owing to incomplete combustion, the latter by loss of gaseous nitrogen, but points out that the Dumas process makes no provision for the complete removal of hydrocarbons. Concordant results are, however, obtained with the Dumas process (hydrocarbons having been completely removed) by the addition of a constant 0·2 per cent. to the Kjeldahl figure, using mercury as a catalyst.

(3) "The Estimation of Lead in Potable Waters and in Urine," by J. C. Thresh, M.D., D.Sc. In estimating traces of lead in coloured moorland waters the influence of the colour is not always removed by making the standards with the same water diluted with distilled water. The presence of even one part of copper in 100 millions reduces the depth of the tint given by lead, and iron in solution also interferes with the colorimetric estimation of lead, and accounts for most of the discrepancies obtained with moorland waters. It is essential that the standard should have the same acidity and contain the same acid as the water or urine under examination. A sensitive method of testing for lead in urine is described, and it is shown that three kinds of filter paper contained sufficient lead to cause urine which was free from lead to give a positive result in the test.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held at the offices of the Association on November 8, Sir William Pearce, in the absence of the Chairman, occupying the Chair.

In response to a letter which had been addressed to all members of the Association, it was stated that only two firms had reported actual difficulties with Local Authorities in connexion with terms of contract. The matter is being followed up with the view to securing a form of contract between buyer and seller that will bind both parties.

A letter from the Federation of British Industries, asking for co-operation of the Association in making a survey as to the present position of "costing" throughout the industry. The Council agreed to assist, but the General Manager was authorised to point out to the Federation that whilst costing is a recognised works function throughout the Industry, there is no standardised system adopted except in the Acid Section.

The Council decided to press the Government for further reductions in taxation, and in doing so, to point out that there is still room for economy to be practised by the Government.

The General Manager reported a visit he had received from the Secretary to the Bribery and Secretary Commissions League, and the Council authorised the sending of a letter expressing their sympathy with the objects of the League.

A report was presented by the General Manager on the arrangements in connexion with the Chemical Section of the British Empire Exhibition, from which it is interesting to learn that the Palace of Industry was handed over by the builders to the Exhibition authorities on Monday last. It is also gratifying to learn that £2750 has already been promised, or subscribed, towards the costs of the Scientific Exhibit.

The question of competitive awards was considered by the Council on a proposal made by the Fine Chemical Section of the Association, but, without expressing any opinion, it was referred to the Committee of Exhibitors to deal with.

A report from the Transport Manager indicated that the Traders' Co-ordinating Committee have met the Railway Companies on the question of the retention of Exceptional Rates, and it is hoped that a means will be devised whereby the Traders will be saved the necessity of scheduling the Exceptional Rates they wish to keep after the "Appointed Day."

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

In addition to the addresses delivered at the third congress, notes of which were given in our last issue, it is of interest to record some of the papers read before the various sections as these are of more than usual interest.

The question of fuel alcohol occupied most of the attention of the Fuels Group, before which Messrs. C. W. Watson and Dr. W. R. Ormandy read a paper on "Bench Tests of Mixtures of Alcohol and Heavy Petroleums." The tests were so satisfactory that the fuel has been tried on a large scale for uses with motor buses. Experiments with a mixture of 100 parts of a certain petroleum and 10 parts of alcohol showed that the addition of alcohol to petroleum of medium quality improved the yield, diminished the explosion, and allowed a fatter spark to be used, the exhaust gases being free from disagreeable odours. Monsieur Pétrick described the use of "Dynalcol" consisting of 421·3 parts of alcohol (96°), and 571·70 of benzine, which has been used on a large scale for motor lorries. Various speakers treated the question of national fuel in France, methods being suggested to ensure regular and intensive production of the alcohol required.

In the Heavy Chemicals Group, Professor C. Matignon discussed the stock of combined nitrogen produced in France by organic, vegetable and animal life, and Monsieur G. Claude followed with a paper on the reduction in price of fertilisers. As it appeared that the hyper-pressure system in France would shortly yield an annual production of 300,000 tons of ammoniacal nitrogen, it was evident that nitrogen produced cheaply could not be combined with expensive sulphuric acid of no fertilising value. This sulphuric acid could be advantageously replaced by the chlorine wasted in large quantities by the Solvay soda process. On treating a solution of sodium chloride in ammonia with carbonic acid, the sodium is precipitated as a bicarbonate, the ammonia being transformed into ammonium chloride which can be separated. According to recent tests ammonium chloride, weight for weight of nitrogen, is equal in fertilising value to the sulphate and, moreover, is much less expensive. Sylvinite ($KCl+NaCl$) could be used as a cheap source of salt, for if the salt used in the Solvay process is replaced by sylvinite the sodium of the sylvinite will be precipitated as bicarbonate, whereas the potassium chloride would remain with the chloride of ammonia, thus giving a combined nitrogenous and potassic fertiliser. In this way ammonia and carbonate of soda would be produced by the help of chlorine and sodium respectively, that cost nothing. Monsieur Claude also pointed out that the only reason for transforming natural phosphates into superphosphates was to enable them to be introduced into the soil in an extremely fine state of division. If the phosphate could be reduced mechanically to this fine state of division, a similar result should be obtained and at the same time a costly operation avoided. This, he suggested, could be done by grading the ground phosphate by means of a current of air along a long tunnel, the larger particles being deposited almost immediately, the finer particles being carried farther away, and precipitated by the Cottrell process. A plant working on these lines is already producing 3 m.t. per day in Morocco, and cultural tests of the product carried out by Monsieur Claude appear to have given good results.

Monsieur Briaux discussed the comparative assimilability of tricalcium phosphate and phosphates of aluminium and iron, showing that aluminium phosphate was slightly better than tri-calcium phosphate for the production of dry matter, and considerably better as regards the fixation of phosphoric acid by the plant, whereas ferric phosphate was decidedly less assimilable than the other two phosphates. Further work by the same author indicated that advantage should be taken of the acidity of certain soils to render soluble a large part of the phosphoric acid in natural phosphates, thus postponing the necessity for liming and marling. Monsieur Graftin, President of the Belgium Chemical Society, showed that, in Belgium, phosphates from the Mons basin, after fusion with fluxes such as phonolite, alkali carbonates, siliceous slag, felspar, etc., yielded highly assimilable phosphates, the process marking new progress in the utilisation of mineral phosphates.

The utilisation of peat as a fertiliser was treated by Prof. C. H. Berthelot, who stated that a mixture of ground peat superphosphate and potash gave good results on medium soils. Peat could also be mixed with natural lime, dried blood, and leather wastes and other organic matters, the nitrogen of which is absorbed and fixed by the turf.

Monsieur Ginselm discussed the rational utilisation of organic wastes in agriculture, and Dr. J. G. Lipmann (U.S.A.) spoke on sulphur as a fertiliser with special reference to the production of potatoes and the treatment of potato scab, flowers of sulphur being mixed with ground mineral phosphates.

Monsieur Rabati suggested the use of sulphuric acid solutions containing 4 to 12 per cent. by volume of 65° Bé acid, at the rate of 1000 litres per hectare as a spray to destroy weeds in cereal crops.

Sir John Russell next discussed micro-organisms of the soil and Monsieur E. Kayser spoke on the nitrogen fixing power of the azoto bacter, pointing out the variability of this power and its causes.

Agricultural bacteriology was the subject of a paper by Monsieur G. Truffaut who discussed nitrogen fixation from the point of view of partial sterilisation of the soil.

The Société de Chimie Industrielle is to be heartily congratulated on its recent meeting, which has proved so suggestive and interesting.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Vol. VIII is now in preparation and will be issued early in 1924. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members. Vol. I is out of print, but copies of Vols. II, III, IV, V, VI, and VII may be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d., and 7s. 6d., and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d. and 12s. 6d. respectively. If Vols. II, III, IV, V, VI, and VII are ordered at the same time as Vol. VIII, the set may be obtained by members for £2 2s. 6d., and by non-members for £3 15s. The appropriate remittance must accompany every order. The books are sent to purchasers post free.

CORRESPONDENCE

A QUESTION OF STYLE

Sir,—We note with surprise your shyness in using the Latin adjectives "optimum" and "maximum" to agree with English nouns. We thought that their long residence in the English language had so completely naturalised them that their association with words of Anglo-Saxon lineage would not offend even the most scrupulous, and surely no renitency ought to be expressed to the union of "optimum" and "conditions." We believe they are both of pure Latin parentage.

Personally, we feel queasy about using a noun as a verb, though we will admit that present day usage and convenience of expression have legitimised this conversion of "motor." This use, however, jars our delicately adjusted poise, as we are enlivening the hours of our daily "chemistrying" by a little "literaturing."—I am, Sir, etc., C. Burrows Morey

Buffalo, New York
October 26, 1923

[We have no objection to the use of "maximum" as a noun; "optimum conditions" seem to be merely the best conditions expressed by means of a singular adjective agreeing with a plural noun; the phrase is discordant to us and for that reason we dislike it, but we are perhaps unduly sensitive. We are also rendered uneasy by the too frequent use of a noun as a verb, and our minds do not function, or condition, or action, in that manner without some sense of impropriety.—Editor.]

THE CHEMIST AND BUSINESS TRAINING

Sir,—A playful interpretation of a paragraph in my letter of October 17 is displayed in the somewhat grotesque criticism levelled at an expression which, in fact, was taken verbatim from your Editorial of October 12. It will be obvious to your readers, however, that our discussion really concerned young men in their "twenties" who had spent a reasonable time in laboratory and lecture-room in training for the profession of chemistry. Calculations on the prospects of "the man of thirty-eight" therefore do not apply.

May I be permitted to draw attention to the excellent article in a recent *Journal*, by Mr. J. H. West, A.M.Inst.C.E., on "The Chemist and Industry"? The cases quoted therein afford striking examples of what might be avoided if the problem of business training for chemists were seriously tackled and solved. Mr. West shows clearly that the capacity to "think industrially" is a desideratum the importance of which is not yet fully recognised either by raw University graduates or by manufacturers as a body. No one will deny that business instinct is a gift which is not possessed by every man, but at the same time I would suggest that much talent of this kind is doomed "to blush unseen" for want of the proper opportunity.

Without attempting to dogmatise in any way, we may still assert that there are many phases of industry, as yet untried, in which the young trained chemist might combine his scientific knowledge with a certain amount of common-sense applied to the control side of operations. Promise of special acumen in the desired direction should lead to increased responsibility and admission to the "inner councils" of which Mr. West speaks; the right man would justify his appointment in the long run.

It is not too much to hope that, in the near future, opportunities will be created in our industrial concerns whereby ability to "think industrially" will be recognised and fostered, with eventual benefit to employer and employee.—I am, Sir, etc., William Doran

Department of Organic Chemistry,
Liverpool University

BRITISH DYESTUFFS INDUSTRY

Sir,—The comment of the Clayton Aniline Company on my letter of the 21st ulto., would lead your readers to believe that I had given the price of 12s. 3d. for Direct Sky Blue FF, as the then current market quotation. My letter was a comment on Professor Morgan's article in which, in the course of developing an argument on what he considers to be unfair competition to which British dyestuff makers are subjected, he stated that the B.D.C. produced Sky Blue FF at 12s. 3d. per pound and for large quantities they were prepared to take the exceptionally low price of 4s. 3d.

My comment pointed out that the price of 12s. 3d. was twelve times pre-war price of Sky Blue FF, following on with this sentence:—

> "If prices on this basis are essential to maintain the Industry as a national necessity, the Colour Users' argument is, that the whole burden should not be borne by him."

It is only fair to point out that the corresponding product of Sky Blue FF, as marketed by the Clayton Aniline Company, is weaker than Chlorazol Sky Blue FF, and therefore its price must necessarily be a lower one.—I am, Sir, etc.,

C. M. Whittaker

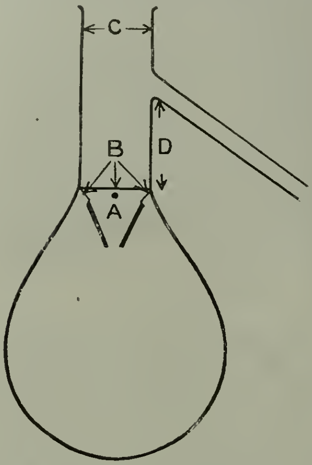
Cheadle Hulme, Cheshire
November 7, 1923

A MODIFIED CLASSEN FLASK

Sir,—I append sketch and particulars of a modified Classen flask which I have devised, and used with success, in the hope that it will be of interest to some of your readers.

Several distillations under reduced pressure (as low as $p=10$ mm.) were carried out, the distillate being very clear and pure.

For a 250 c.c. flask the following dimensions held: $C=2{\cdot}5$ cm. in diameter, $D=7$ cm. *B* are four small holes, about $\frac{1}{16}$ in. diameter, as near to the point of fusion of the cone and to the flask proper as is possible. *A*, the cone, has an orifice 0·7 to 0·8 cm. in. diameter. The bulb of the flask should be pear-shaped. The side-neck resembles that on an ordinary distilling flask.



The flask is used in conjunction with a capillary tube, which passes through the same stopper as the thermometer.

The chief drawback to this design is the trouble which would be experienced in extracting the pieces of capillary tube from the flask, should the capillary break, but a "thick-walled" capillary would minimise such a risk.—I am, Sir, etc., G. A. Collinson

The University, Leeds
Nov. 7, 1923

LEGISLATION AND THE CHEMICAL INDUSTRY

Sir,—It appears probable that legislation will shortly be proposed, having for its object the protection of British industries, and it is seasonable to inquire whether the chemical industry is now in a position to make its influence felt in the principles as well as the wording of any new statutes Parliament may pass.

The Safeguarding of Industries Act produced a crop of correspondence in your columns ranging from the pontifical to the merely querulous. Sir William Jackson Pope flogged a dead horse with amazing skill, and we still miss the weekly photographs of him visualising with papal infallibility the orgies of misrepresentation before the Board of Trade referee. Some sections of the society also held most useful debates on the meaning of the vague chemical terms vaguely punctuated which were allowed to pass into the schedules to the Act. It is safe to say that had these debates been held before the Act was passed instead of after, the Act might have been substantially improved and some injustices mitigated.

I write to suggest that the industry should keep a watchful eye on the legislature next Session. Perhaps this could best be done if each section were to appoint a small Parliamentary Committee who would study the list of Parliamentary and Stationery Office publications, published monthly by H.M. Stationery Office at a nominal cost, and also, if funds permit, the Parliamentary Debates in the House of Commons, which cost £2 10s. per Session, delivery extra. If such a committee were to bring to the immediate notice of the section any projected legislation which touched the interests of the members there would be a chance for chemists to debate at their meetings or discuss in these columns what the effect of the proposals would be and to put their views before their Members of Parliament.—I am, Sir, &c., Foster Sproxton

Manningtree,
November 2, 1923

A CORRECTION

Sir,—May I ask you to correct the statement in your report of the recent Congress of the French Society of Chemical Industry, that I was present as a representative of the Chemical Society. That august democratic body cast me out early this year, after fifty years' continuous wear, as useless. I received no mandate and went to Paris to represent myself alone, and, if possible, the courtesy of a past generation—as an act of politeness and policy, in response to the direct invitation of the French society, of which I am privileged to be an honorary member—a privilege I value the more as I am not even an ordinary member of our home society. Throughout my professional career as a technical chemist, this select body has always treated me as a pariah, in fact. In France I am not yet ruled out.

Henry E. Armstrong

PERSONALIA

The Nobel Prize for Chemistry for 1923 has been awarded to Prof. Fritz Pregl, of Graz, Austria. Amongst Prof. Pregl's chief work mention may be made of the isolation of acids in bile, of cleavage products of the egg case of the dogfish, and of the acids of egg albumin, the acetylation of soluble starch, and apparatus for drying under reduced pressure at high temperatures and for extracting aqueous liquids by chloroform. Prof. Pregl is also an exponent of micro-chemistry, a subject on which he has recently published a treatise.

The Nobel Prize for Physics has been awarded to Dr. Millikan, of Pasadena, California.

The following have been elected corporate members of the Institute of Physics: *Fellows*: G. R. Bolsover, J. A. Jones, C. H. Lander, T. Takamine, A. Warren. *Associates*: K. R. Brain, A. L. Gregson, J. S. Grew, J. A. Hughes, E. O. Hercus, T. J. Lonsdale, R. D. Thompson, J. F. Wood.

Mr. M. Dixon (Emmanuel) has been appointed Senior Demonstrator in Biochemistry in the University of Cambridge for five years.

R. Fisher, formerly of the Chemistry Department of the University of Illinois, V. F. Parry, late of the U.S. Bureau of Mines, and W. B. Plummer, formerly research chemist for the Grasselli Chemical Co., have been appointed research chemists in the laboratories of the Combustion Utilities Corporation, New York.

Mr. P. A. Ellis Richards, President of the Society of Public Analysts, has been appointed to the seat on the Departmental Committee on Preservatives and Colouring Matters in Food left vacant by the resignation of Mr. O. Hehner.

Dr. A. Balfour, C.M.G., M.D., B.Sc., director of the Wellcome Bureau of Scientific Research in London, has accepted the directorship of the Rockefeller School of Hygiene, London.

* * *

With regret we record the death of Lt.-Col. A. C. Bishop, chairman of Kemball, Bishop and Co., Ltd., manufacturers of cream of tartar and of tartaric and citric acids.

The death of Dr. Carl Harries, at the early age of 57, marks the loss of one of the pioneer workers in the field of rubber chemistry. Led from early work on the constitution and analysis of rubber to consider the possibilities of synthesising it, Harries discovered that isoprene could be made to polymerise by heating it in the presence of acetic acid for a lengthy period, a caoutchouc-like product being obtained. A further development of the process consisted in replacing the acetic acid by metallic sodium, a method which, however, was anticipated by Dr. Matthews. Perhaps the most important contribution to science due to Harries was his exhaustive work on the formation and properties of the ozonides, a term introduced by Schönbein to designate certain protoxides that give off ozone when decomposed, but now applied to compounds containing the radicle O_3. The formation of ozonides serves to determine the presence and, frequently, the position of a double bond in organic compounds, *e.g.*, as in oleic acid. Born in 1866, Harries was educated at Jena, Munich and Berlin, and became successively assistant to Hofmann and Emil Fisher. From 1904 to 1916 he held the professorship of chemistry in the University of Kiel and for a long time was scientific adviser to the firm of Siemens.

OBITUARY

Dr. J. E. STEAD, F.R.S.

Metallurgical science has suffered a severe loss in the death of Dr. J. E. Stead at the age of seventy-two. For more than fifty years he had been directly engaged in metallurgical work, and during that time he had been associated with some of the most important developments in the metal industries. Trained as an analytical chemist, he had held posts in both copper and iron works before becoming in 1876 a partner with the late Mr. John Pattinson, whose pupil he had been. He gained a great reputation as an analytical authority, and in the course of his consulting practice he came into contact with a great variety of industrial processes, on which his opinion was sought. He was closely connected with the early stages of the basic Bessemer process, and it was he who specially directed attention to the necessity of the after-blow for the removal of phosphorus. The relations between phosphorus and iron were a favourite subject, to which he returned on several occasions, his work being the foundation of our present-day knowledge.

The attention of Dr. Stead was directed to microscopical metallography at the International Engineering Congress held at Chicago in 1893, and from that time onwards he was one of the most active workers in that field. He developed new experimental methods, and made most skilful use of the method of heat-tinting first employed by Martens. A little book on metallography, based on two papers by Osmond, long served as a text-book. Dr. Stead's skill in the preparation and etching of specimens was great, and he had the faculty of recognising and explaining interesting structures in alloys of the most varied kind. In other fields of experimental investigation he frequently obtained important results from small crucible meltings, and he thus contributed largely to our knowledge of slag reactions.

Kind and warm-hearted to an exceptional degree, the personal character of Dr. Stead endeared him to all who knew him. His vast stores of metallurgical knowledge were at the service of all, and a letter from a young metallographer, propounding some difficulty, would promptly bring a long reply, often accompanied by specimens or photo-micrographs. He was an unfailing source of help, to experts and students alike, in scientific perplexities. His intervention in discussions before technical societies was always welcome, and he preserved his genial good humour in controversies, often acting as peacemaker between rival schools. He received several honorary degrees, and was elected a Fellow of the Royal Society in 1903. In 1920 he was chosen as President of the Iron and Steel Institute, and fulfilled the duties admirably for a time, but his health was already failing, and on some occasions he had to delegate his functions to others. He will be greatly missed, but he has left a permanent mark on metallurgical science, and personally influenced two generations of metallurgists. C. H. Desch

NEWS AND NOTES

UNITED STATES

The American Chemical Prize

It is announced (*Ind. and Engineering Chemistry*) that a gift for the promotion of chemistry in America has been received by the American Chemical Society, in the form of an annual prize of $25,000 founded by the Allied Chemical and Dye Corporation. This prize will be awarded annually to that chemist (man or woman, a citizen or resident of the United States of America at the time), who, in a certain year, or through a period of years, has made a contribution of high merit or in some marked way has promoted the betterment of society through the science of chemistry. The award will be made at a meeting of the American Chemical Society, when the recipient will be expected to receive the prize in person, and will be invited to deliver an address before the Society. The name of the prize will be "The American Chemical Prize" (founded by the Allied Chemical and Dye Corporation).

Coke and By-Products in 1921

The coke industry was severely depressed in 1921. The output of by-product coke was only 25,287,622 tons (31,000,000 t. in 1920), and that of beehive coke was less than in any year since 1885, the output being 5,538,042 t. (20,500,000 t. in 1920). The depression in the beehive-coke industry represents one of the most remarkable slumps in the history of any industry, the most slack period being in July, when only 7000 t. of coke were produced daily, being only 7 per cent. of the average daily rate of production during the years 1915-1918. But the outlook improved by December, when the average daily rate of production was 19,000 t. The average price per ton for both beehive and by-product coke was about $3 less than in 1920, which was a year of abnormally great activity. By-products sold in 1921 produced only $60,000,000 gross (about $94,000,000 in 1920), and included 310,188,713 m. cb. ft. of gas, 253,051,649 galls. of tar, 657,001,003 lb. of ammonium sulphate or its equivalent, and 76,917,269 galls. of light oil. At the end of 1921 there were 11,141 by-product coke ovens in existence and 85 under construction, but the number of beehive ovens remaining at the end of the year was the smallest since 1901, many having been abandoned during the year. The total export of coke in 1921 was 306,755 t., valued at £2,760,939 (919,802 t. valued at £9,993,665 in 1920), and imports amounted to 30,990 t. at £336,394 (41,143 at £403,175 in 1920).

Building Materials in 1921

The following are the figures of the outputs of various building materials in the United States in 1921 :—Cement, 96,046,549 barrels (valued at $181,675,440); clay, 1,716,746 short tons ($6,025,300); gypsum, 3,050,984 t. ($23,700,290); lime, 2,532,153 t. ($24,895,370); silica, 184,613 t. ($1,783,036); stone, 63,538,740 t. (valued at $106,962,266). All show a decrease in comparison with the output of the previous year.

Cement.—Both the total output and the total shipments of Portland cement in the United States in 1921 decreased by 1 per cent., and the gross value of the shipments decreased by 7 per cent. The average selling price at mills decreased 13 cents a barrel, or about 6 per cent. The stock reported on hand at the close of 1921 amounted to 12,187,364 barrels. Domestic consumption was estimated at 94,448,455 barrels, and the average factory price per barrel in bulk of Portland cement in 1921 was $1·89. The number of plants manufacturing cement was 115 compared with 117 in 1920, and the total number of rotary kilns reported in plants that operated in 1921 was 740, as against 753 in 1920.

Clay.—The general depression in business had a marked effect on the clay-mining industry in 1921, the output decreasing 45 per cent. and the value 48 per cent., as compared with 1920. Fire clay, which showed the largest output in both quantity and value, decreased 49 per cent. in quantity and 52 per cent. in value as compared with 1920.

Gypsum.—The quantity of gypsum produced in the United States in 1921 exceeded 3,000,000 tons, but was 2 per cent. less than in 1920. The amount of gypsum sold crude to Portland cement factories decreased from 541,901 t. in 1920 to 526,042 t. in 1921. Keenes cement decreased 12 per cent. in quantity and 6 per cent. in value; the average price per ton rising from $14·90 to $16·11. Wall board decreased 52 per cent. in quantity and 24 per cent. in value from 1920, the average price per ton rising from $26·28 to $41·75; blocks and tile decreased 44 per cent. in quantity and 29 per cent. in value from 1920, and the average price increased from $13·12 to $16·65.

Lime.—Total sales of lime in 1921 decreased owing to trade depression, to less than those of any other year since 1904, the output falling in 34 out of the 42 producing States and Territories. The cost of production was generally reported to have been less than in 1920. High freight rates were, perhaps, the greatest obstacle and it was suggested that new plants should be built to supply local trade.

Silica.—The sales of quartz from pegmatite dikes, veins and quartzite in 1921 fell by 83 per cent. in quantity in comparison with 1920. Prices of crude and ground quartz in 1921 averaged $4·63, and $16·89, respectively.

Stone.—The quantity of stone sold in the United States in 1921 was the smallest in six years, showing a decrease of 19 per cent. in quantity and of 20 per cent. in value. The decrease in output was largely due to the depression in the metal industries. Granite produced in 1921 amounted to 4,752,180 t. ($20,592,217); basalt and related rocks (trap rock), 8,524,480 t. ($11,450,899); marble, 315,400 t. ($8,580,416); serpentine, $290,968; limestone, 75,171,000 t.; sandstone, 2,640,460 t. ($6,425,339); bluestone, 53,510 t. ($659,796); miscellaneous stone, 1,685,220 t. ($2,163,801); and crushed stone 43,202,840 t. ($51,717,478).

GENERAL

World Prices of Coal and Iron, 1923

The following statistics compare the prices of coal, coke and iron in the chief consuming countries in June, July and August, 1923, with those ruling in 1913-14. To enable comparison the prices in the various currencies are converted into paper and gold marks.

New Laboratory at the Birmingham Technical School

On October 31 Sir Robert Hadfield formally opened the new laboratory and lecture room in the chemistry department of the Birmingham Technical School.

The need for extension of the chemical department, of which Dr. J. Newton Friend is the head, has long been realised, and even now, though fairly well provided for, more space is required. The recognition of the usefulness of the work of the chemical department is shown in the fact that a number of industrial firms of Birmingham and the district have made contributions towards equipping two rooms, formerly used as store rooms. One is principally equipped for research on corrosion, and the other is a lecture room with a library and museum. In addition, the pharmaceutical laboratory has been completely refitted. The funds have come in donations ranging from a few pounds to a generous contribution of £150 in three yearly instalments of £50 each year by Messrs. Phillip Harris and

On August 31, 1923, the pound sterling was worth 35 million paper marks.

Co. Another important donation of £142 16s. was given by the Midland Varnish, Paint and Colour Manufacturers' Association. Other donations included £50 from Messrs. Dunlop, £50 from Messrs. Mitchell and Butler, and £25 from Messrs. Chance and Hunt. The total of these contributions exceeds £425. The chemical department has received additional help in the form of research prizes offered by Sir R. Hadfield, F.R.S., the Dunlop Rubber Co., the Mond Nickel Co., and the Pharmaceutical Associations of Birmingham and Staffordshire. The school also benefits by two grants made personally to the head of the department, Dr. Friend, who receives a grant of £150 from the Royal Society and one of £100 from the Carnegie Research Fund for work on corrosion. These grants take the form of a micrographic apparatus loaned or given to Dr. Friend, and housed in a special dark room

Gypsum, 1913-1919

The Imperial Mineral Resources Bureau has now published the section of "The Mineral Industry of the British Empire and Foreign Countries" devoted to gypsum (pp. iv+31, price 9d.), and giving a digest of relevant statistical and technical information relating to the war period. Below are given the figures showing the world's production of gypsum in 1913 and 1921 in long tons:—

	1913	1921
United Kingdom ..	285,338 ..	264,840

Manganese deposit in Java

Indications of manganese ore have been discovered in the Residency, Djokjakarta (Java) over an area of nearly two miles. It is undoubtedly a sedimentary deposit, and the layer has an average thickness of from 3-4½ ft., increasing in places to 5½ ft. In the lower bed of the seam pyrolusite has been found which contains 50 per cent. of manganese, but the upper bed is not so pure. By calcining, an export product can be made with 63 per cent. of manganese. Manganese ores also occur in the lake districts of Celebes. These are highly ferruginous, and on analysis show 19·3 per cent. loss by burning, 3·46 per cent. SiO_2, 47·60 per cent. Fe_2O_3, 24·09 per cent. Mn_3O_4, 1·18 per cent. NiO, and 0·46 per cent. Cr_2O_3.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Nov. 8*)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Hardware	412/7/1/1/173*
British India	Copper wire woven sheets, steel (tender)	**
Canada ..	Paper	12236/E.D./M.C./2
China ..	Dental, photographic and rubber goods, perfumery	521
Far East ..	Paint, varnish, soap ..	522
Finland ..	Tinned steel wire (tender)	8276/F.R./E.C.
France ..	Petroleum products, rubber chemicals ..	510
Greece ..	Tar	11729/F.E./M.C./2
Netherlands	Tinplate	511
New Zealand	Steel pipes (tender) ..	12474/E.D./E.C./2
Portugal ..	Lubricating oil ..	516
Siam ..	Brass wire gauze, paint, varnish, paper, soap (tender) ..	11568/F.E./G.P.
South Africa	Glassware	505
,, ,,	Cast Iron (tender) ..	11162 and 12491/E.D./E.C.
Spain ..	Leather	518
United States	Iron, brass, copper and pewter goods ..	20878/F.W./M.C./2

TARIFF CUSTOMS EXCISE

Australia.—A dumping duty has been applied to caustic soda.

Bulgaria.—Increased import duties are applied to articles of wax, ceresine, paraffin, stearine or soap; perfumery, skins, silk, brass, bronze, nickel, and aluminium.

Germany.—The internal tax has been increased on sugar.

Guatemala.—Modifications have been made in the duties on silk, rubber goods, celluloid, soap, perfumery.

Poland.—The duties on acetic acid, sugar, oil, asphalt and tar have been increased.

Portugal.—Export surtaxes are now levied on fertilisers, oils, hides, and resin.

REVIEWS

ALCOHOLIC FERMENTATION. *By* PROF. A. HARDEN, Ph.D., D.Sc., F.R.S. *Third edition. Pp.* 194. *London: Longmans, Green and Co.*, 1923. *Price 6s. 6d.*

This is one of the well-known series of monographs on biochemistry and the fact that it is the third edition is sufficient evidence of its appreciation. The rapid progress of the subject has necessitated the extension of the work by 38 pages. Soon after the discovery of zymase by E. Buchner in 1897, investigations were commenced at the Lister Institute on a-cellular fermentation, but it was not until six years later that Prof. Harden took up the subject on which he has extended our knowledge so considerably that he has become the leading authority in this country.

As might be expected the monograph deals principally with the chemical side of the subject, that is to say with a-cellular fermentation, but in the historical summary forming the introduction the evolution of our knowledge of fermentation is lucidly described from the days of Stahl, Lavoisier, Liebig, Pasteur, Buchner, etc., to the present day. "The subject still remains," says the author, "one of the most interesting in the whole field of biological chemistry."

Availing himself of the fact that the literature of alcoholic fermentation is less extensive than that of some other branches of biochemistry, Prof. Harden has produced a work which really constitutes a treatise on the subject as well as a complete bibliography. The text is divided into ten chapters and the various views on the chemistry of fermentation are clearly and impartially described. The monograph is remarkably free from typographical errors, the only slip noticed being on page 101, where it is stated that "methylene blue is added with the object of deviating the hydrogen supposed normally to be used in reducing the *alcohol* to *aldehyde*."

Prof. Harden may be congratulated in having brought up to date a monograph on one of the most important and suggestive branches of biochemistry. ARTHUR R. LING

JOURNAL OF SCIENTIFIC INSTRUMENTS. *Produced by the Institute of Physics with the Co-operation of the National Physical Laboratory. Vol. I, No.* 1, *October*, 1923. *Pp.* 32. *London: The Institute of Physics,* 10, *Essex Street, Strand, W.C. Price* 2*s.* 6*d.*

In the first number of the Journal of Scientific Instruments a standard is set which augurs well for the future of this new publication. The following list of contents will serve to indicate its scope:—(1) The Measurement of True Height by Aneroid, by L. N. G. Filon, M.A., D.Sc., F.R.S.; (2) Two New Methods of Measuring the Internal Diameters of Transparent Tubes, by J. S. Anderson, M.A., D.Sc., Ph.D., and Guy Barr, B.A., D.Sc.; (3) On an Improved Temperature Control for the Pulfrich Refractometer, by Prof. T. M. Lowry, D.Sc., F.R.S., and R. G. Parker, B.Sc.; (4) A New Relay and its Application to Sustaining Pendulum Vibrations, by H. A. Thomas, M.Sc.; (5) A General-Purpose Recording Drum, by Prof. C. V. Boys, F.R.S.; (6) The Chain Balance, by Prof. Sir Flinders Petrie, D.C.L., LL.D., F.R.S.; (7) A New Recording Kata-Thermometer, by E. H. J. Schuster, D.Sc.; (8) Miscellanea; (9) Reviews.

There must be but few scientific workers who can escape the necessity of employing physical methods at some phase of their investigations, and to them the new journal will prove invaluable. Well printed on good paper, the journal appeals to both eye and mind, and one cannot but offer it a hearty welcome and prophesy its success.

HANDBUCH DER LACK- UND FIRNISINDUSTRIE. *By* DR. F. SEELIGMANN *and* EMIL ZIEKE. *With the collaboration of* W. SCHLICK *und* DR. F. ZIMMER. *Third edition. Pp.* 827. *Edited by* E. ZIEKE *und* DR. HANS WOLFF. *Berlin*, 1923.

The second edition of the "Handbuch der Lack- und Firnisindustrie" appeared in 1914, and was at the time the best book on the subject in any language. It was a mine of information and rich in references to the world's literature of the varnish industry. The editors of the new edition have been unable to obtain the co-operation of Dr. Seeligmann, who is resident in America. The book has been reduced from 1074 to 827 pages by re-arrangement of the material and deletion of much out-of-date information. The editors are to be congratulated on having produced a valuable treatise on the subject, but the new material is too limited, and it is evident that a comprehensive treatment of the subject in one volume is impossible. Division into several small monographs by different authors would give to readers the detailed information required, unless copious references were inserted in the one volume. The new edition lacks the broad and well-informed character of the earlier editions. There is no review of literature, and the recent work quoted is almost entirely from German sources. In view of the researches in other countries, especially in America, the result tends to show that German progress since 1914 has been slow, which detracts largely from the value of the book. Very many instances could be given and a few may be quoted:—

The account of recent work on abietic acid, Japan lacquer, fish and "stand" oils, and the viscosities of oils and varnishes is too short, and recent statistics on raw materials are not given. The section on insulating varnishes is a reprint of the account given in the second edition. The lack of adequate reference to recent investigations in other countries is difficult to understand, since one of the editors is a recognised authority on paint and varnish problems. A most interesting chapter on the defects of varnishes has been deleted in the new edition, which is much to be regretted. In spite of these criticisms there are chapters of great value. The treatment of China wood oil is full and fairly up-to-date. A useful summary of the properties of rosin esters, driers and enamels is given, and the old classification of varnishes has been properly modified. An excellent chapter on German methods of varnish analysis is communicated by Dr. Wolff, full of information, but suffering from the general defect of the whole work. The old formulæ and recipes are retained and no new ones inserted, but rather general principles, which will disappoint works-manager readers. In the chapter on the manufacture of varnishes many new figures of plant appear, which are not really up-to-date. The old foreign friends of Seeligmann and Zieke's *Handbuch* will be disappointed and will feel that an excellent opportunity has been lost of enhancing the reputation of the former editions.

RHUS DERMATITIS FROM RHUS TOXICODENDRON, RADICANS AND DIVERSILOBA (POISON IVY): ITS PATHOLOGY AND CHEMOTHERAPY. *By* JAMES B. MCNAIR. *Pp. xi*+298. *Chicago*: *The University of Chicago Press*, 1923. *Price* $4.00.

The genus *Rhus* furnishes a considerable number of useful products, including the tanning materials sumach and Chinese galls, the yellow dyestuff "young fustic" and the natural varnish, which forms the raw material of the lacquer-ware industry of China and Japan. The three species of *Rhus* with which Mr. McNair deals are, however, most undesirable members of the flora of North America since they secrete an intensely irritant substance, which produces dermatitis in those who come into contact with the plants. Mr. McNair has been at work on these noxious species since 1917, and this book consists largely of papers contributed by him to botanical, chemical and medical journals in the United States. It gives a very complete account of the whole subject from the botany of the three plants to the character of the dermatitis produced by their secretions. Some suggestions for remedial treatment are made in a chapter rather grandiloquently entitled "A Contribution to the Chemotherapy of Rhus Dermatitis and Tentative Method for Treatment."

Chapter X deals with the Chemistry of the Poisonous Principle about which next to nothing is known, though it has been given several names of which the author contributes "lobinol." He appears to have disposed of several unwarranted speculations about its nature which is all to the good. The method he used for the preparation of "lobinol" is hardly likely to have yielded a pure product, and in view of the interest which the frequent cases of *Rhus* poisoning evokes in the United States, it is to be hoped that, as the author himself suggests, someone will continue this work and isolate and determine the nature of the toxic substance.

It is curious that irritant substances of this kind have not attracted more attention from chemists. Some progress has been made in determining the components of Japanese lacquer, which also contains a toxic substance probably similar in nature to that of the poison ivy, and the dermatitis caused by East Indian satinwood has been shown to be due to an alkaloid, chloroxylonine, but the irritant constituents known to occur in other timbers of industrial importance such as West Indian satinwood, and certain of the boxwoods have not yet been characterised, though they give rise to cases of dermatitis in workmen from time to time. Mr. McNair's book should serve to direct attention to this field of work.

T. A. HENRY

PRINCIPLES OF CHEMICAL ENGINEERING. *By* W. H. WALKER, W. K. LEWIS and W. H. MCADAMS. *First edition. Pp. ix*+637. *London : McGraw-Hill Publishing Co., Ltd*, 1923. *Price* 25*s*.

The authors claim that this book is the "outgrowth of extensive engineering practice" in which they have profited by many ideas offered in the way of suggestions, criticisms or advice. The greater part of the text is said to have been in use for some time as students' notes at the Massachusetts Institute of Technology, where the authors are professors of chemical engineering.

It would appear that the United States are far ahead of this country in the study of chemical engineering. The book under review is in itself evidence of this fact.

The subject matter is treated in a thoroughly scientific manner, which will no doubt prove very pleasing to the student of physical chemistry or to the chemist possessed of a mathematical bent. The practical man or works manager, on the other hand, will probably not be so well satisfied because of the lack of description of works processes and the paucity of useful information regarding methods of working. In other words, the writers confine themselves strictly to their title—principles of chemical engineering, and in this way keep the size of the treatise within reasonable limits for a single volume. This kind of book has been very much wanted of recent years and will repay close study, close study being necessary fully to understand the text, which is by no means diffuse.

The book may be divided roughly into five parts :—

1. The principles of industrial stoichiometry are reviewed. The pound mol. is strongly recommended as a basis of calculation; this and the pound atom are used throughout the text. A number of pages are devoted to the working out of typical examples of problems occurring in chemical works' practice. These problems have to do chiefly with the measurement of gases. One is inclined to think that too much space is taken up with these calculations, which to a well-trained chemist seem rather elementary. More space, on the other hand, might have been given to a study of the principles of practical measurement and testing.

2. The phenomena accompanying the flow of fluids and the flow of heat are treated in an able way mathematically. The problems that are here stated and solved ought to prove of great service to the student of this rather perplexing branch of the subject.

3. Fuels and combustion are discussed very lucidly and effectively, if rather briefly, in Chapter VI. The following chapter is devoted to furnaces and kilns, Chapter VIII to gas producers. The Morgan and the Chapman gas producers are the only ones illustrated.

4. The principles of crushing and grinding, and mechanical methods of separating materials are dealt with in a well thought out, systematic and scientific way, the treatment of the subject being mathematical wherever advantageous. The important subject of filtration is briefly but clearly expounded in Chapter XI. A longer reference to the Cottrell method of electrostatic precipitation (only a dozen lines are given) would have been welcome. Centrifuges, too, are left almost entirely in the cold.

5. Processes relating to vaporisation are discussed at considerable length and are usefully treated from the standpoint of vapour-pressure equilibria. Evaporation, humidifying, dehumidifying, condensing, drying and, finally, distillation come under this heading. These subjects occupy 235 pages of the text.

As one might expect, the examples of plant chosen for illustration are nearly all American. But, none the less, chemical engineers in this country will be amply repaid by a careful perusal of the treatise.

The whole style of the book (binding, paper, printing and illustrations) is excellent.

W. B. Davidson

LEGAL INTELLIGENCE

Contracts for the Supply of Soda Ash
Scrimaglio v. Thornett and Fehr

On October 24, Mr. Justice Greer heard the action of Signor Scrimaglio, of Genoa, against Messrs. Thornett and Fehr, London, in respect of contracts for tallow and soda ash.

The defence admitted the plaintiff's claim for £392, an over-payment in respect of certain packages of vegetable tallow, subject to a counterclaim which arose out of two contracts by which the plaintiff agreed to purchase from defendants 200 tons of soda ash. For the defence it was alleged that the plaintiff had committed a breach by refusing to take up the shipping documents tendered. In accordance with the contract the plaintiff's liability in respect of his repudiation of the contract was referred to arbitration. The defendant company appointed Mr. C. Mangold as arbitrator, and as no arbitrator had been appointed by the plaintiff, Mr. Mangold held the arbitration and awarded the defendants £4800 damages, which the defendant company now claimed. For the plaintiff liability for alleged repudiation of the contracts was denied, and it was claimed that the only arbitration contemplated was arbitration in London in the usual way and under the Arbitration Act, *i.e.*, arbitration by a single arbitrator appointed by the Court. The plaintiff did not concur in the appointment of Mr. Mangold, and said that arbitration in the usual way in London meant arbitration according to the rules of the British Chemical Trade Association, which meant that the arbitrator was appointed by the Association, which was not the case. For the defence it was claimed that the habitual method of arbitration in the chemical trade was by two arbitrators and an umpire.

Mr. E. Fehr gave evidence that the rules of the British Chemical Trade Association did not apply to this contract, and Mr. Pitman contended that arbitration in the usual way meant according to the ordinary law of the land unless there was any stipulation to the contrary. Mr. Justice Greer thought that the usual way of conducting commercial arbitrations was with two arbitrators and an umpire, but Mr. Pitman said it was always subject to the rules and conditions of various trade associations. Mr. E. J. Parry, B.Sc., said that arbitration in London in the usual way meant arbitration under the Arbitration Act by one arbitrator. Probably the majority of people who employed these words anticipated the employment of two arbitrators and an umpire.

His Lordship, in giving judgment, said that the evidence showed that most forms of contract stipulated for two arbitrators and an umpire, and it was the rarest possible thing in the chemical market to find a contract which provided for a single arbitrator. The words meant arbitration in the usual manner in the chemical trade in London, and on the evidence that meant arbitration before two arbitrators and an umpire. It was remarkable that, although the British Chemical Trade Association had adopted a definite form of contract with a number of conditions, the chemical trade, with some small exceptions, preferred their own forms with the words "arbitration in the usual way." Therefore he decided in favour of the defendants that the award was valid and binding so long as it was not set aside and he was told it was too late to apply to set it aside. He therefore entered judgment for the defendants for the amount of the counterclaim, £4800 less £392 due to the plaintiff, with costs. A stay of execution was granted on terms.

REPORTS

Report on the Industrial and Economic Situation in Czechoslovakia, dated March, 1923. *By* S. P. Elliott, *Acting Commercial Secretary, Prague. Department of Overseas Trade. Pp.* 48. *H.M. Stationery Office*, 1923. *Price* 1*s*. 6*d*.

The chief difficulties with which Czechoslovakia has had to contend in the past year were due to the country's comparatively strong financial condition. The crown has appreciated in value till now it is fairly steady at about 160 to the £, but prices in general have not fallen proportionately. As the country can meet home demands by 30 to 35 per cent. of its industrial production its existence depends on its ability to export, but the rise in value of the crown and the weakening of the currencies of neighbouring countries made export difficult. Exports in 1922 were only about 3 per cent. less than in 1921, whereas imports fell by about 25 per cent., but the figures do not show the critical state of the country, as many of the exports were finished articles sold from stock at a loss, and owing to decreased production, imports of raw materials were smaller.

The glass industry, one of the most important in the country, did very well during the first half of the year, but the rapid rise in value of the Czech crown in August was catastrophic. Nevertheless in some lines the exports of glass reached and even surpassed the level of those of the old Austro-Hungarian Empire. Prices at present, however, are high owing to the cost of raw materials and transport. The coal industry was depressed: home consumption dropped to about one half of the pre-war figure, and exports dwindled steadily during the year. The two factors which kept the industry going were the prohibition of imports, and the necessity of Germany to import coal. The total production amounted in 1922 to 9,906,261 t. of hard coal and 18,942,020 t. of lignite, each about 15 per cent. less than in 1921. The metal industry is in a bad way; prices have fallen considerably.

Since the abolition of State control in October last, a syndicate has been in operation to eliminate competition between sugar producers. The total production of raw sugar was 720,969 metric tons and 318,179 t. was exported.

Since the formation of the republic there has been a falling off in trade with Austria and adjacent countries, whilst that with more Western European countries has increased, though this must be regarded as due principally to the low purchasing power of local currencies. Imports in 1921 were valued at 22,433 million Kc. and exports at 27,312 mill. Kc. Though in 1922 the weight of exports exceeded considerably that of imports, the actual values may show much less difference. The fact that many goods which could be supplied by British producers are already made in Czechoslovakia itself under a system of protection, hinders the British merchant from developing trade, but it is hoped that a commercial treaty into which Great Britain and Czechoslovakia are entering will remove many of the difficulties.

Report on the Economic and Financial Situation of Egypt, dated April, 1923. *By* E. H. Umlock, *British Commercial Agent, Cairo. Department of Overseas Trade. Pp.* 56. *H.M. Stationery Office*, 1923. *Price* 1*s*. 6*d*.

The year 1922, in spite of indications to the contrary, such as the favourable trade balance, large exports of cotton and a good budget surplus, was unsatisfactory economically. Although in 1922 the total quantity of cotton exported, 6,479,372 t., was above the average for recent years, its value was considerably less owing to the marked falls in cotton prices.

Industries in Egypt are divisible into three categories, mining, general and native. Among the former may be mentioned petroleum, obtained from the Suez area and refined, as is also some imported oil, at Suez. Anglo-Egyptian Oilfields, Ltd., produced 171,923 t. of crude oil in 1922. Phosphates from the Red Sea coast and Upper Egypt are sent to Europe and Japan, as the high cost of sulphuric acid prohibits the local production of superphosphate. Production of phosphates in 1922 amounted to 60,220 t. against 122,024 t. in 1921. Manganiferous iron ore is mined in Sinai and sent chiefly to Belgium, Holland, and the United Kingdom; the output in 1922 was 104,143 t. and 111,523 t. were exported. Crude sodium carbonate and sulphate are recovered from salt lakes in the Delta and the soda lakes at Wadi Natroon. Limestone and clay are quarried for cement production. There are several industries of a general nature connected with cotton, such as cotton-seed crushing and soap making. Sugar refining is important, and the country is capable of producing 11,000 t. of alcohol annually. The native industries are principally domestic, dyeing of fabrics being an important branch.

Imports in 1922, £E43,333,938, were about 22 per cent. less than in 1921 (*cf. J.*, 1922, 486 R), principally owing to the decrease in imports of coal and cereals. The principal imports included hides, skins, and leather, £E2,829,157; wood and coal, £E3,842,267; stone, earthenware and glassware £E1,265,934; dyestuffs, tanstuffs and colours, £E441,423; chemical and medicinal products, and perfumery, £E2,964,733; metals and metalware £E5,357,161. Exports amounted toi £E48,716,418, about 25 per cent. more than in 1921, consisting mainly of raw cotton and cereals.

Imports from the British Empire fell in 1922 by £E5 millions, and those from the United States by £E6½ mill., thus accounting for most of the fall in imports. Although part of the reduction of the British imports is due to trade depression, and to competition from countries with low currency values, it is not entirely due to these factors, and instances are given to emphasise the view that British manufacturers should do more to foster the demand for the goods they produce rather than leave this to their agents.

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN URUGUAY, JANUARY, 1923. *By* E. A. CLEUGH. *H.M. Vice-Consul, Montevideo. Pp.* 30. *Department of Overseas Trade. H.M. Stationery Office*, 1923. *Price* 1*s*.

The two problems facing Uruguay at present are the state of the national finance and the universal industrial depression. Uruguay is eminently pastoral and depends on European markets to dispose of her meat supplies—a difficult matter under present conditions. Nevertheless, the country is economically sound and undoubtedly will react favourably when European conditions improve. The live stock industry has been in a bad state for some time, and State assistance has had to be given to many farmers. Sealing and whaling are important industries. The excellent results obtained recently in the sealing industry have led to a State inquiry into the present methods of working with the view to eventual nationalisation. The proposal referred to in the last report (*cf. J.*, 1922, 182 R) to nationalise the manufacture and sale of alcohol has not yet materialised, nor has a more recent similar proposal in connection with drugs.

The year showed a slight tendency towards improvement in trade compared with 1921, mainly in the later half, but the balance of trade is against Uruguay. The value of imports in 1922 is given as $81,778,640, and of exports at $77,458,046 (the value of the Uruguyan dollar varied between 40d. and 45d. during the year). Uruguayan importers have always shown themselves anxious to trade with the United Kingdom, though they became discouraged by the fall in the value of the dollar, and some difficulty in getting their requirements met. Their interest has, however, increased recently, but strong competition has to be met from Germany, the United States, France and Belgium.

REPORT ON THE ECONOMIC AND INDUSTRIAL CONDITIONS IN THE SERB-CROAT-SLOVENE KINGDOM (JUGOSLAVIA), DATED APRIL, 1923. *By* CAPT. E. M. HARVEY, *H.M. Commercial Secretary, Belgrade. Department of Overseas Trade. Pp.* 40. *H.M. Stationery Office.* 1923. *Price* 1*s*. 6*d*.

The year 1922 proved unsatisfactory to the trader and bright prospects in view at the beginning of the period (*cf. J.*, 1922, 513 R) were not fulfilled. This was largely due to the restrictions placed on exchange transactions in order to maintain the value of the dinar, but which also hindered genuine trade. Since the control was removed trading conditions have improved, though the dinar has decreased in value.

In spite of earlier reports to the contrary the grain harvest in 1922 proved average, and the grape crop was abundant, though the wine will be of inferior quality. Much propaganda work is being done to induce farmers to grow sugar beet. In 1922 30,000 to 35,000 tons of sugar were produced in the country, representing about one half of the home consumption.

Little has been done to develop the mineral resources of Jugoslavia, largely owing to lack of capital and of transport facilities. Boring for oil continues in the Save-Drave district, but apparently no definite results have yet been obtained.

Industry is still in its infancy. Lack of capital is a great difficulty, and the shortage of skilled labour and inadequate railway communications also prevent development. Various measures taken in 1922 to reduce prices proved disastrous to industry.

Exports in 1922 amounted to about 3,000,000,000 dinars. Prunes took first place among the exports, timber coming next. Italy and Austria were the chief buyers in Jugoslav markets, the former taking 29 per cent. and the latter 25 per cent. of the total exports. The United Kingdom took 2·4 per cent. Since the war Switzerland has taken a bigger share than previously.

Many restrictions were placed on importation in 1922 in order to assist the restoration of a favourable balance of trade and the value of national currency, among them being one prohibiting the importation of luxury articles. In December, however, these restrictions were removed.

Trade with Great Britain was not so great as anticipated. In one or two commodities, such as copper and tin, a fair amount of business has been done. It is pointed out that the best method of introducing new goods with any success is to provide a local agent with adequate stocks, rather than insist on payment through London credit accounts.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No material changes have taken place in the heavy chemical market, but a more hopeful tone has developed, with an improved demand from the textile trade.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 9d.—4s. 3d. per carboy d/d.
Acid Nitric 80° Tw.	£21 10s. per ton makers' works.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal.

Acetate of Lime—	
Brown	£12—£13 per ton d/d. Demand steady.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 10s. per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. per gall. 60% O.P.
Solvent	6s.—6s. 3d. per gall. 40% O.P.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 1d.—1s. 2d. per lb. Fair inquiry.
Crude 60's	3s. 4d. per gall. Market quieter.
Acid Cresylic—97/99	2s.—2s. 5d. per gall. Firm, with good demand.
Pale 95%	1s. 11d.—2s. 4d. per gall.
Dark	1s. 6d.—2s. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—10d. per gall. Plenty of enquiries.
Unstrained	8½d. per gall.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.

Benzale, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall. d/d. buyer's works.
Pure	1s. 9d—1s. 11d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Good business being done.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d. per gall. Market sluggish.
Solvent 90/190	1s. 2d.—1s. 3d. per gall. Very little business.
Naphthalene Crude—	
Drained Creosote Salts	£7—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9 10s.—£11 per ton.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	130s.—140s. per ton, according to district and time of delivery. Several inquiries. Market firm.
Pyridine—90/140	22s.—22s. 6d. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Quieter.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Better demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The shortage of spot supplies of a number of products continues and prices are in consequence considerably higher for a few of the pharmaceutical chemicals which are in regular demand.

Acid, Acetic 80% B.P.	£47 10s. per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 7d. per lb. In strong demand. Most makers fully sold ahead.
Acid, Benzoic	2s. 9d. per lb. for ordinary quality. B.P. quality worth 4s. 6d. lb. Stocks negligible.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 4½d. per lb., less 5%, for ton lots. Firmer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic. Cryst	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d.—2s. 7d. per lb. Firm market.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Home trade poor. Raw material slightly easier.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 2s. 9d. per lb. Small stocks.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. per lb. for English make.
Ammon. Carbonate B.P.	£32 15s per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Demand very poor
Barbitone	17s. per lb. Neglected.
Benzonaphthol	5s. per lb. Quiet.
Bismuth Salts	A steady market. Prices according to quantity :
Carbonate	12s. 9d.—14s. 9d. per lb.
Citrate	11s. 4d.—13s. 4d. ,,
Salicylate	10s. 2d.—12s. 2d. ,,
Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	7½d. per lb. Remain very firm.
Ammonium	8½d. ,, ,,
Sodium	8d. ,, ,,

Calcium Lactate	2s. 9d. per lb. for best English make.
Chloral Hydrate	4s. 3d. per lb. Position very firm.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	7s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 13s. 6d. per lb. Still advancing.
Hexamine	4s. 6d. per lb. Very firm market.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	1s. 11d.—2s. 3d. per lb., according to quality.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£77 10s. per ton, less 2½%.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 72s. 6d. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	2s. 10d. per lb. for carboys. Very scarce. Higher values expected.
Methyl Sulphonal	Has rapidly advanced to 21s. per lb.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 5d. per lb.
Phenacetin	7s. 6d. per lb. In better supply.
Phenazone	8s. 3d. per lb. Remains very firm.
Phenolphthalein	7s. 9d. per lb. Very firm. Shortage imminent.
Potass. Bitartrate—99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	15s. 8d.—15s. 11d. per lb. Good steady market.
Potass. Permanganate	10d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. per lb.
Salol	4s. per lb.
Sod. Benzoate	3s. per lb. Scarce.
Sod. Citrate, B.P.C., 1923	1s. 9d. per lb. for cwt. lots.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Nitroprusside	16s. per lb. Less for quantity
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 10d. per lb., and Crystal at 2s. 11d. per lb. Firm and very active.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	Very much higher at 25s. per lb.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	3s. 6d. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s. 9d. to 13s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	18s. 6d. ,, ,,
Linalyl Acetate	18s. 6d. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Ketone	47s. 6d. ,, ,,
Musk Xylol	13s. 6d ,, ,,
Nerolin	4s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,
Rhodinol	60s. ,, ,,
Safrol	2s. ,, ,,
Terpineol	3s. ,, ,,
Vanillin	25s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 11d. ,, ,,
Bergamot Oil	13s. 3d. ,, ,, spot.
Bourbon Geranium Oil	37s. ,, ,,
Camphor Oil	80s. ,, ,,
Cananga Oil, Java	9s. 6d ,, ,,
Cinnamon Oil, Leaf	5d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 9d. ,, ,,
Ceylon	Very little on offer, too many parcels arriving containing spirit. These have been seized by the Customs.
Clove Oil	10s. per lb.
Eucalyptus Oil 70/75%	2s. 9d. per lb.

Lavender Oil—		
French 38/40% Esters	26s. per lb.	
Lemon Oil	2s. 10d. per lb.	
Lemongrass Oil	2¾d. per oz.	
Orange Oil, Sweet	11s. 9d. per lb.	
Otto of Rose Oil—		
Bulgarian	34s. per oz.	
Anatolian	26s. per oz.	
Palma Rosa Oil	24s. 6d. per lb.	
Peppermint Oil—		
English	70s. per lb.	Market very unsteady.
Wayne County	15s. 6d. per lb.	Market very unsteady.
Japanese	12s. 6d. per lb.	Market very unsteady.
Petitgrain Oil	8s. 9d. per lb.	Dearer.

TRADE NOTES

London Joint City and Midland Bank, Limited

At an extraordinary General Meeting of the shareholders of the London Joint City and Midland Bank Limited, held at the Cannon Street Hotel, London. E.C. 4, on Friday. November 9, 1923, a resolution was passed changing the name of the Company to Midland Bank Limited. A confirmatory meeting will be held on November 26 next.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications made in October for licenses under the Dyestuffs (Import Regulation) Act, 1920, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee :—

The total number of applications received during the month was 520, of which 428 were from merchants and dealers. To these should be added the 40 cases outstanding on October 1, making a total for the month of 560. These were dealt with as follows :—

Granted, 423 (of which 381 were dealt with within 7 days of receipt).

Referred to British makers of similar products, 75 (of which 63 were dealt with within 7 days of receipt).

Referred to Reparation supplies available, 53 (all dealt with within 2 days of receipt).

Cancelled, 1.

Outstanding on October 31, 1923, 8.

Of the total of 560 applications received, 498, or 89 per cent., were dealt with within 7 days of receipt.

Complaints under the Safeguarding of Industries Act

The Board of Trade has received formal notices of complaint that Rongalite, Sodium Formaldehyde Sulphoxylate and Zinc Formaldehyde Sulphoxylate have been improperly included in the lists of articles chargeable with duty under Part 1 of the Act. These complaints will be submitted in due course to the Referee appointed for the purposes of the Act and any person interested should communicate immediately with the Assistant Secretary, Board of Trade, (Industries and Manufactures Department), Great George Street, S.W. 1.

Trade Information

A New Photomicrographic Camera.—Although photomicrographic methods are in common use in technical laboratories, the apparatus used is not always of the most convenient kind. It is of interest therefore to direct attention to the handy Lucas photomicrographic camera, made by Euner and Amend, Third Ave., 18th to 19th Street, New York. This instrument has the great advantage that either plates or films can be used with it ; further, it is compact, easily operated, little affected by vibration, and capable of exact longitudinal adjustment. The price of the complete camera in a wooden case, together with two films, but without a microscope, is $60.

"Sira" Abrasive.—Messrs. R. & J. Beck, Ltd., of 68, Cornhill, London, send us particulars of the new "Sira" abrasive prepared according to the formula of the British Scientific Instrument Research Association. This abrasive can, it is claimed, advantageously replace emery, being more rapid and economical in use. "Sira" abrasive is tough and does not break down during use, and has the further advantage that it does not cease to act until much debris has accumulated.

An Improved Method of Sawing Metals.—We have received a pamphlet describing an improved method of sawing metals, which is said to halve the time and cost of sawing. The improvement consists in the use of a saw blade of high-speed tungsten steel, having a patent set which enables it to be sharpened many times, a novel saw-grinding machine being provided to form the correct shape of teeth. To enable full benefit to be obtained from the high-speed steel saw, the sawing machine has been designed to run at a high speed. Full particulars can be obtained from Messrs. E. G. Herbert, Ltd., of Atlas Works, Chapel Street, Levenshulme, Manchester.

Bleaching is an old industry, but there is still room for improvements in technique, and attention may be directed to pamphlets issued by the Castner-Kellner Alkali Co., Ltd., 257, Royal Liver Building, Liverpool, dealing respectively with bleaching by means of liquid chlorine in conjunction with bleaching powder, and bleaching by means of hydrogen peroxide. It is advocated that chlorine, supplied as liquid in cylinders, should be bubbled through the tank in which bleaching powder is being mixed, the free lime being converted into calcium hypochlorite, thereby raising the strength of the bleach liquor by 35 to 40 per cent., and reducing the quantity of waste sludge by three-quarters. Stronger liquors can thus be made up and fewer mixings are required, so that not only is less labour required, but the availability of the bleaching powder is improved, time lost in washing sludge to conserve bleach solution is reduced and the maximum output of the mixing plant can easily be doubled.

In the pamphlet on sodium peroxide, the uses, advantages, and properties of this universal bleaching agent are described and precautions are set out that should be observed in storing and using it. Useful practical hints are given to aid the user in preparing goods for bleaching—an essential point—in preparing the bleach liquor and in the after-treatment required. The pamphlet terminates with tables of equivalents, including the common hydrometer and thermometer scales, and it is stated that the Castner-Kellner Co. will consider any problem connected with sodium peroxide in which laboratory experience or small-scale laboratory trials can be of service.

Scouring is a process which, in domestic experience at any rate, is not unknown to end disastrously, so that any method based on accurate knowledge will be sure of a welcome. The Weston Chemical Co., Ltd., Royal Liver Buildings, Liverpool, have sent us a booklet which describes the uses of " Westropol " solvent scourers, non-inflammable fat-solvents incorporated in soaps in such a way as to become either soluble in or emulsifiable with water. These scourers are stated to have no action on metals and to contain no injurious or objectionable ingredients. Special products such as Westropol, Westrol and Westoran are available for particular materials, and it is claimed that much more effective results can be obtained with the use of these special products than with ordinary means, as not only are very obstinate mineral oil or fatty stains removed, but there is no felting, even the most delicate material is uninjured, work is accelerated and infected materials are sterilised.

Oil-extraction and degreasing.—In a further pamphlet sent by the Weston Chemical Co. an account is given of the varied uses of the chlorine derivatives of ethane and ethylene as non-inflammable, non-combustible, and non-inflammable solvents. These solvents include tetrachlorethane (Westron, a solvent for fats, oils, resin and sulphur), and trichlorethylene (Westrosol, for oils, fats, resins and rubber). Both these solvents can be used in most ordinary types of extractors, and are recovered with facility by steam distillation. Westrosol has practically no action on iron, but when Westron is used, iron parts should be protected with a coat of lead. Further information on the many uses of these interesting solvents can be obtained from the makers at the address given above.

New Water-resisting Glue

The new highly water-resistant blood albumin glue (c.*f. Chem. and Ind.*, 1923, p. 840), which is made by the addition of paraformaldehyde and ammonia to blood albumin, can be used with presses of the same sort used in gluing with animal, vegetable or casein glues, and can be applied without the use of a hot press. It has sufficient strength for use in plywood, as may be seen in the fact that plywood test specimens which were placed in the fungus pit of the Forest Products Laboratory under conditions of excessive humidity during one year, required a shearing force of 300 lb. to break them apart. Specimens placed in water for one month proved equally strong. The new glue formula is dedicated to the free use of the public.

Vol. 42 NEW SERIES LONDON, NOVEMBER 23, 1923 No. 47

EDITORIAL

WE may be pardoned if we say that the story of Agib, Prince of Tartary, has haunted us since the recent meeting of the Chemical Engineering Group. He would be bold indeed who dared to question the ability of any chemical engineer to strum a march upon the loud theodolite or blow the gay pantechnicon all night—suitable refractories would be recommended at least—but on this occasion we did not even need the piano's martial blast to wake the echoes of the past, for Prof. Hinchley was discoursing on potash. Not the potash of juvenile experiments with match-boxes or the remedy for incipient colds, but the material of prime importance to agriculture which has hitherto been supplied almost solely from the Stassfurt deposits. It was a fascinating story that Prof. Hinchley had to tell, and seldom can a long and difficult piece of investigation have been summarised so beautifully by a few equations. The importance of the new source of potash described can be realised when it is stated that the volcanic region in Central Italy contains sufficient leucite to supply the world's requirements in potash for several hundred years. Commercial extraction has been found not only possible but is being accomplished, and the raw material has many unique properties. In general the iron content of minerals is often so combined that electro-magnetic separation is impossible, but by good fortune—which was resented jocularly by one speaker—the iron in leucite can be separated quite readily by electromagnetic treatment. In powder form the mineral is practically equivalent in fertilising value to potassium sulphate of the same potash content, and the silica it contains can apparently be made use of by the plant. Leucite, being zeolitic in character, is of use in softening water, and it can be employed in many ways for the production of chemicals. Potash alum of high purity can be obtained by dissolving granular leucite in sulphuric acid, no objectionable gelatinous silica being formed, and iron can be removed by passing the solution over fresh mineral. The silica that remains dissolves at once in caustic soda and yields a very pure sodium silicate. Practically pure potassium chloride and pure hydrated aluminium chloride, or, alternatively, hydrated aluminium oxide and silica, are produced by treatment with hydrochloric acid, and caustic soda can be made by treating powdered leucite in an autoclave with caustic lime. Many possible applications, such as in the ammonia process for making alkali, at once suggest themselves for such a protean material, and it seems obvious, as Prof. Hinchley pointed out, that our chemical industry cannot afford to ignore the potentialities of leucite.

* * *

It is interesting and even pleasant to watch from a serene spot, and at a safe distance, storms and other troubles, but it is even more exciting to see a break in the clouds and a glimpse of sun and hope. The devastated and impoverished condition of Europe provides but few of such encouraging signs and it is the more necessary to call attention to them. A year ago Austria's financial state was parlous, her currency was depreciating rapidly towards the infinitesimal, starvation and bankruptcy stared her in the face. To-day, thanks to the League of Nations and the capable experts who were appointed to improve matters, conditions are much better. Private deposits in the banks have increased from two million gold crowns a year ago to thirty-two millions, the monthly deficit in the national finances is a third of what it was; during the last six months the number of the unemployed has become half; the currency is now stable. Our great chemical industry will revive and with it the demand for trained chemists when our other industries are again more prosperous, and these doubtless depend to some extent on the prosperity of the world. Chemists must surely welcome the development we have mentioned and will hope to see this remedy applied elsewhere. Those who advocate duties, capital or other levies, free trade or other debatable topics, cannot fail to be impressed by this solid and recent achievement.

Mr. Rex Furness' article in this number on colour in nature opens up a whole vista of idle visions. Though science ever takes us back step by step from the obvious to the unknown, and though we are getting gradually to the stage when we can identify many of the natural colouring matters, describe their constitution, and explain the chemical processes by which they are built up, nevertheless the main fact that the red poppy propagates red poppies and the yellow ones produce yellow offspring is as mysterious and incredible as ever. What an astonishing complexity must exist in the tiny seed, able to arrange that in the grown-up plant there shall be a stalk and flower of definite size, shape and colour, that the leaves shall have specified areas, divisions and markings, that these shall have hairs of a particular length, breadth and thickness, and so on! Does the seed consist entirely of chemical molecules arranged in some special way or does inheritance involve something in addition? Can there be some tendency, some tradition or some influence, independent of atoms or molecules? This will be very surprising, but any other explanation seems equally difficult.

* * *

We are indebted to our contemporary, *The Chemist and Druggist*, for a most curious instance of bureaucratic interference with the private rights of the populace. One has almost become accustomed to legislative control of the use of alcohol, whether industrial or potable, passports and registration forms are necessities of life in some countries (though in this country too many forms have to be filled in annually for the comfort of most of us), and "grandmotherly legislation" has become a stock phrase of political argument. But we have never before heard of a whole nation being medicated forcibly. It is well known that potassium iodide is an excellent remedy for the disease, goitre, so common in many of the mountainous districts of Europe. Some kindly bureaucrat, having heard of this, concluded that the metabolism of the inhabitants of Austria was in decided need of improvement. The means were at hand, the decree went forth. Salt production in Austria is a Government monopoly, so, in future, culinary salt in that country will contain 0·005 grams of potassium iodide to each 1000 grams of sodium chloride. On inquiring further into this Attic *trouvaille*, it will be found, however, that, as each Austrian citizen consumes approximately 7 or 8 kilograms of salt each year, his or her metabolism will be stimulated by the ingestion of no less than 0·04 grams of potassium iodide annually, supplied without extra charge. One trembles to think of the consequences were our own bureaucrats to realise the possibilities of this ingenious method of safeguarding the nation's health, though a united effort of the chemical industry could produce results surpassing the powers of imagination.

COLOUR IN NATURE

By REX FURNESS

Introduction

During his recent visit to this country, Prof. Bancroft delivered a number of lectures on the subject of the colour of birds' feathers. As no full report of these lectures has appeared in the technical press, it was suggested that a general review, embodying Bancroft's work, would prove of interest. In the following article, Bancroft's papers in the American journals have been largely drawn upon, whilst in addition, Willstätter's classic work on the anthocyans, the colouring matters of many of our most beautiful flowers, has been reviewed. The colour of flowers is directly due to the presence of pigments, capable of isolation, whilst the colour of many feathers is produced in the entire absence of pigments, by the scattering of light or interference phenomena. Some attention is given to the question of the part played by oxydases and peroxydases in the formation of pigments in plants.

Colour in Nature

Colour is a characteristic of all forms of nature, wherein it has both utilitarian and decorative functions. Thus, the green colouring matter of plants, chlorophyll, acts as a photo-catalyst in the reaction between carbon dioxide and water, and is essential in this primary reaction of the complex process of plant growth. The charming hues of many flowers attract certain pollen-bearing insects, and colour therefore plays its part in the propagation of the species.

In the animal kingdom, colour is made use of in ensuring self-protection. The art of camouflage had been developed to a high degree amongst animals thousands of years before man demonstrated his superiority by employing it to assist him in the wholesale destruction of his kind. Protective colouring amongst animals is recognised by zoologists, and is displayed on almost every hand. The stripes and general colour effect of the tiger's skin protect him in the jungle by limiting colour contrasts and rendering him less visible in his natural surroundings. The sandy skin of the lion, the spots of the leopard and the stripes of the zebra serve similar purposes in particular localities. The animals of the polar regions are white, some, for instance the northern hare, assuming their white coats only in winter. Similarly, mottled and spotted fish are almost invisible in the sand. The colour and general physical form of many insects render them almost indistinguishable from the bark or leaves of trees, or from some other feature of their surroundings. The looper caterpillar can scarcely be distinguished from a dead twig, and many butterflies and moths simulate dead leaves. The same principle applies in imitative colouring, as when an animal with no powerful means of defence resembles one which is known to be dangerous.

Of quite a different order is the part which colour plays in sexual attraction amongst the humming birds and other birds possessing gay and decorative plumage.

The appreciation of the beauty of colour by mankind was probably prehistoric in origin, for there are many references to it in the earliest historical writings. The artistic sense evident in the selection and application of pigments and naturally coloured objects increased as civilisation advanced. In illustration there may be noted the contrast between the application of a crude woad extract to the body by the ancient Briton and the employment of the beautiful Tyrian purple for the dyeing of fine textiles by the peoples of the Roman and earlier civilisations.

The love of colour to-day is universal. Although nature's colourings cannot be surpassed, man finds a great pleasure in the beauty of many of his own productions—stained glass windows, afire in the rays of the sun, delicately coloured ceramic wares, cunningly worked, artificial silks, dyed in soft hues with the aid of the ever-increasing range of coal-tar dyestuffs. He has discovered how to colour all kinds of textiles, furs and leathers, and to beautify his dwellings by means of decorative papers, paints, lacquers and the like.

The love of colour is so deeply ingrained in human nature that a blinded man, once having seen and appreciated artistic colour arrangements, continues to enjoy them in retrospect, and to create in imagination new and wonderful effects. The dull bronze depths into which his sightless eyes seem ever to be gazing represent his only approach to actual colour vision—if the train of dazzling incandescent sparks which occasionally crosses the bronze void be excepted —but his imaginative faculties give him all the delights of colour sensation. His philosophy tells him to refrain from mourning a loss which cannot be repaired, and persuades him to believe, perhaps foolishly, that he is the gainer, when, as the warm beams of the westering sun fall upon his face, he transforms even the most watery of sunsets into a kaleidoscope of blended colours such as is seen in actuality only by a Turner.

Origin of Colour Effects in Nature

The ultimate reason why any object appears coloured to the eye is bound up, of course, with the phenomena of light absorption, reflection and refraction, but we are accustomed to regard colour as a result of the presence of a pigment. Thus, it is quite true that the colours of many of our most beautiful flowers are directly occasioned by the presence of the anthocyan pigments, which can be extracted and identified as definite chemical entities. The colouring of many birds' feathers, the blue colour of the sky, the sunrise and sunset tints and the colour of blue eyes are all directly the result of light phenomena. The actual final effects may be modified by the presence of a dark pigment, which often serves as background, or by the presence of a yellow pigment which, superimposed over a structural blue, results in a structural green colour. For the purposes of broad contrast, however, we may regard the colour of flowers as due to the presence of pigments, and that of blue feathers as due entirely to light effects, produced in the absence of pigments. The latter, the so-called structural colours, are divided into objective structural colours and subjective structural colours, the former being caused by the scattering of blue light by a turbid medium and being independent of the angle of incidence of the light. Subjective structural colours, on the other hand, are due to light interference phenomena, as in the case of the coloured "Newton's rings," and are responsible for the brilliant flashing colours showing a metallic lustre and seen, for instance, in the tail feathers of the peacock.*

Blue, Green, Non-Iridescent Colours of Feathers

The blue and green colours of birds' feathers are due entirely to the scattering of blue light by the disperse system constituting the feathers, with the aid of a yellow pigment superimposed upon the feather structure, in the case of green colour effects. Thus, no blue pigment can be extracted from the feathers of the blue bird, the blue jay, the kingfisher or the indigo bunting. The blue light, incident upon the feathers, is scattered by the disperse system, consisting of minute air cells in the horny structure of the feathers, the former representing, of course, the dispersed substance and the latter the disperse medium. The air cells or pores exist in the outer layers of the barbs of the feathers. The blue colour observed is the ordinary "Tyndall blue," and is common in turbid media, such as the sky and the human eye. The blue of the sky is, according to Bancroft, due to light scattering in the disperse system, which, contrary to that of feathers, consists of a gaseous dispersion *medium* and a solid disperse *phase*.

It is not suggested that every blue colour found in the feathers of birds is produced in the absence of blue pigments, and it is admitted that a "synthetic" structural blue feather has not yet been produced. Contrast, for instance, the imitation of a blue sky effect in an artificial atmosphere containing fine particles (*V-infra*). The theory of the cause of the blue colour of the feathers of the birds noted above fits into Bancroft's general conception of the scattering of blue light by disperse systems. These systems are of three classes, namely, a solid in a gas (as in the case of the sky), a gas in a solid (as in the case of blue feathers), and a liquid or solid in a liquid (as in the case of blue eyes).

---

* It is impracticable to enter into a discussion of the various causes of colour in any detail in this article. A standard textbook of physics should be consulted, or the concise explanations of interference colours, Newton's rings and light scattering, which are available in the standard works of reference may be found to probe deeply enough into the question, so far as it concerns the chemist. Bancroft's four papers, Parts 1 to 4 of "The Colour of Colloids" (*J. Phys. Chem.*, 1918, p. 601, 1919, pp. 1, 154, and 253) discuss the questions of light absorption, reflection and refraction, with special reference to the colour of colloids—and therefore apply to the disperse systems constituting birds' feathers, blue skies and blue eyes—and form a masterly review of our knowledge of colour phenomena.

▲

Before passing to a consideration of the iridescent colours of birds' feathers, a short account of the scattering of light by the first and third noted disperse systems may be given.

THE BLUE OF THE SKY

The blue colour of the sky has been attributed to the phenomenon of light scattering from the time of Leonardo da Vinci, but even to-day the *exact* mechanism is under discussion. It has been suggested (*cf.* Bancroft) that the scattering is effected by finely-divided solid particles or dust, suspended in the air, whilst finely-divided water particles may provide an alternative explanation. Artificial blue "skies" have been created in disperse systems of solids in gases. Nichols states, however, that whilst there are reasons for regarding the sky as a turbid medium—a disperse system—experimental observations on the spectrum of sunlight cannot be entirely explained by the assumption of relatively coarse particles in the atmosphere. Rayleigh has shown that dust free air and other gases can scatter light, and in every case the scattered light is blue.

It thus appears that it is unnecessary to postulate an atmosphere containing dust, in order to account for the blue of the sky.

The sunrise and sunset colours are due to selective absorption of light. On account of the deeper layers of air through which the sun's rays have to pass (slantwise) at sunrise and sunset, the extent to which the blue light is scattered reaches a maximum. The residual red and orange light illuminating atmospheric haze and clouds provide the basis for the glorious tints so commonly observed (*cf.* Gibbs, "Disperse Systems in Gases," 4th Report on Colloid Chemistry, 1922, p. 179).

BLUE EYES

The structural blue colour of the eye is again due to light scattering by means of finely-divided particles suspended in the liquid medium of the iris. The structural blue is modified, in the cases of green, brown and black eyes, by the coloured layer before the iris, namely, the uvea, which also acts in preventing the red blood from showing and cutting down reflection from the back of the eye (*cf.* Bancroft, "Colour of Colloids," *J. Phys. Chem.*, 1919, p. 154).

IRIDESCENT COLOURS OF BIRDS' FEATHERS

The brilliant flashing metallic iridescent colours of the tail feathers of a peacock or the throat feathers of a humming bird, are subjective structural colours, and are caused by the thin laminæ in the barbules of the feathers. No bright pigment can be extracted from these feathers, nor is the colour effect destroyed by bleaching materials. The effects vary with the angle of incidence of the light to a greater extent than can be accounted for on the theory of selective reflection. The iridescent colours are true interference colours, akin to the coloured "Newton rings," as they are visible by reflected light and not by transmitted light. Indeed, as Bancroft says, the beautiful tail feathers of the peacock, viewed by transmitted light, show no more signs of colour than do the feathers of a crow.

An examination of the structure of iridescent feathers of many birds shows that the barbules—wherein the colours originate—consist of a core of fibrous or granular matter, two microns in thickness, covered with three thin laminæ, apparently in contact, each 0·4 microns thick. A final thin plate or laminated structure completes the barbule, which acts as a multiple thin film. A dark brown pigment provides a background for the interference colours, and aids the production of the flashing metallic lustre, but the colour effects remain until almost the whole of this pigment has been removed, and can then be observed under the microscope.

The curvature of the barbules is the factor determining the final beauty and delicate blending of hues in the iridescent feather. This is due to the different angles at which different parts of the barbule are viewed and, as noted above, the interference colours change with the changing angle of incidence of the light. Plain thin films cannot create the soft blended hues obtaining in the feathers and built up in the curved laminated structure.

The differences of colour and gradations of effect upon a single feather are due, in addition, to slight variations in the thickness of the colour-producing laminæ. A surprisingly small difference in thickness will cause a marked alteration in the interference colours, and it is marvellous, as Bancroft says, that the same general types of coloured feathers are produced generation after generation with such exactitude, when a relatively minute change in the thickness of the microscopic films would entirely alter the general appearance.

The iridescent metallic colours of many birds' feathers are thus structural in origin, being caused by the play of light interference phenomena upon a dark background, and softened and blended by reason of the curvature of the barbule surface, the curved laminæ of which do not give the garish colours of plain thin films.

The Colour of Flowers and Fruits

The colour of flowers and fruits is, in general, due directly to the presence of one or more pigments in the structure, and is not purely structural. The white of the lily is, however, a structural colour, resulting from the disperse system of minute air pores in the petal. The number of colouring matters in nature is enormous, and it is impossible to consider more than one special class. The anthocyan pigments have been selected for review, because they create some of the most beautiful colour effects in flowers, and in addition have been the subject of a profound, painstaking and brilliantly successful series of researches by Willstätter and his associates.

The anthocyans have attracted the attention and curiosity of chemists since the days of Berzelius, and although much interesting work has been reported, the greatest step forward was the isolation of numerous crystalline individuals by the improved methods of Willstätter and the characterisation of the class of anthocyanin pigments.

The anthocyanins are all related to three substances, namely cyanidin, pelargonidin and delphinidin. The red, blue and violet colours of flowers are due to the presence of these substances, their methyl derivatives or their glucosides. The latter are known as the cyanins, pelargonins and delphinins respectively, and are by far the most common form of the anthocyan pigments, it being comparatively rare that the free anthocyanidins occur in flowers. Even in these instances, the amounts are relatively small as compared with the amounts of the glucosides.

The glucosides are formed from the anthocyanidins and either dextrose, rhamnose or galactose. Dextrose is the principal sugar found, whilst galactose only occurs in a single instance. The wide variety of the anthocyanins is dependent upon variations in the nature and number of the sugar residues, and to differences in the position in the complex molecule—in their points of attachment to the anthocyanidin nuclei.

The colour of a particular flower depends not only upon the particular anthocyanin or anthocyanins present, but also upon the concentration, the nature of the cell sap, the presence of other bodies such as tannin or iron salts. In addition, the anthocyans may exist in the plant in the free state, as salts or as oxonium compounds with mineral or organic acids. In the respective conditions, the anthocyans form the basis for violet, blue and red shades.

As an instance of the variation in the amounts of pigment present in flowers, the following figures are of interest. Cyanin, the colouring-matter of the blue cornflower exists in the dried petals to the extent of 0·7 per cent. The same pigment occurs in the dark red garden variety to the extent of 14 per cent. Again, violanin, the glucoside of delphinidin with rhamnose and dextrose, forms the colouring matter of the violet pansy, the dried petals of which contain 33 per cent. of the weight of the anthocyanin.

A list of some anthocyanins is given here, and the extent of their occurrence in nature will become apparent if it be remembered that scores of other glucosides have been prepared in a pure state, following extraction by water or dilute alcohol, fractional precipitation, crystallisation, and so forth. It will also be apparent that the same anthocyanin may occur in flowers and fruits of widely differing colour. As noted above, all the anthocyanins are glucosides of three parent anthocyanidins (or their methyl ethers), namely, pelargonidin, cyanidin and delphinidin—the hydrochlorides of which have, respectively, the formulæ $C_{15}H_{11}O_5Cl$, $C_{15}H_{11}O_6Cl$ and $C_{15}H_{11}O_7Cl$.

Cyanin occurs in the blue and dark red cornflower, the rose, dahlia, and in some pelargonia. It is found in the bilberry and black and wild plum, and an isomer, mecocyanin, is largely responsible for the colour of the scarlet poppy. Both cyanin and mecocyanin are derived from cyanidin, dextrose being the sugar constituent of the natural glucoside.

Asterin and chrysanthemin, found in the aster and chrysanthemum respectively, are isomeric glucosides from cyanidin also, but contain only one dextrose residue in the molecule of the pigment, whereas cyanin contains two.

Keracyanin and prunicyanin again are isomeric with the cyanin of the cornflower and the mecocyanin of the scarlet poppy, respectively, but differ in that they contain two rhamnose residues. These glucosides are present in the cherry and sloe respectively.

Delphinidin glucosides occur in the larkspur, wild mallow and pansy, whilst the corresponding glucoside of delphinidin dimethyl ether, namely, oenin, is found in wine. The glucoside is present in the skin of the grape in conjunction with the free delphinidin, namely, *oenidin*—a circumstance which is by no means common.

Violanin presents us with an instance of two different sugar residues in the molecule, dextrose and rhamnose. The parent anthocyanidin is delphinidin.

The anthocyan pigments have been employed in the past for dyeing purposes, but the colours obtained upon textiles were mostly fugitive. To-day, for reasons which are obvious, they have no commercial significance.

It is impracticable to enter here into a discussion of the constitution of the anthocyanins and their parent anthocyanidins, but it may briefly be stated that they resemble the important flavones, the yellow colouring matters of many plants. They may be regarded as reduction products of the corresponding members of the flavone series. From the present point of view, colour, it is of interest that the anthocyans become darker as the hydroxyl content of the molecule increases, from polargonin through cyanin to delphinin.

Many other types of coloured substances are to be found in our flowers, fruits and plants generally, but to give a list in the absence of some slight discussion would be an intrusion upon valuable space. The anthocyans are a representative class, however, and particularly noteworthy as they are the immediate cause of some of the most beautiful exhibitions of colour in nature.

The Formation of Pigments in Flowers

The apparent simplicity with which plants synthesise the pigments responsible for the infinite variety and gradations of colour effects stands in strong contrast to the laboured efforts of the chemist to manufacture artificial colouring matters. The processes by which pigments are produced, in common with the general life processes of plants, are, however, complex and do not always receive from chemists the attention and study they merit. It is fitting, therefore, to indicate briefly the function which enzymes perform in the formation of flower pigments, since, although there are other important questions pertaining to this study, the rôle of oxidases has been determined with care and precision.

Pick, in 1883, first suggested the hypothesis that oxidases are concerned in the formation of pigments in plants, and several observers have supported this theory. In 1910 Miss Wheldale suggested that the colourless chromogen by the oxidation of which a pigment is produced, occurs in the plant in the form of a glucoside. Enzymes of the emulsin type hydrolyse the glucoside, itself resistant to oxidation, and the free chromogen is then oxidised by atmospheric oxygen, activated by an oxydase.

The definite proof of the intimate connexion between the presence of oxydases and the formation of pigments in the various parts of the plant has been afforded by the work of F. Keeble and E. F. Armstrong (*Journal of Genetics*, 1912, II., 277). The isolation of *glucosides* as the principal constituents of the anthocyan pigments may demand a modification of the hypothesis of Miss Wheldale (or, alternatively, it is conceivable that the pigment produced according to this view of the process, may subsequently combine with a sugar through the synthetic influences of enzymes), but in any case, the explanation of the function of oxydases is secure upon the basis of the work of Keeble and Armstrong.

These investigators first established a reliable test for the presence of oxydases (and peroxydases). Alcoholic solutions of benzidine and α-naphthol were found to give specific colour reactions with oxydases, the petal or other part of the plant being first decolourised by the reagent and then stained a rich dark brown when benzidine was used, α-naphthol producing a lilac blue or lavender. The addition of hydrogen peroxide may be required, and in some instances with benzidine, a temporary blue or blue-green colour may form prior to the development of the characteristic brown formed in the cell structure. Benzidine, moreover, registers the presence of oxydases in the epidermis of the petal, whilst both benzidine and α-naphthol react with oxydases present in the cells constituting the bundle sheaths. It is emphasised, too, that negative results must be accepted with caution, for, as will appear later, certain flowers contain inhibiting substances, which prevent the formation of the characteristic test colours.

With the aid of this valuable test, it has been clearly demonstrated that, in general, the distribution of pigments in flowers coincides exactly with that of oxydases. The oxydases, it is true, are more widely distributed than are the chromogens, but the distribution is in conformity with the oxydase-chromogen hypothesis, as will be illustrated by several typical examples, culled from the many available in the paper noted.

The flowers of *Primula sinensis* and of *Dianthus barbatus* (Sweet William) show most epidermal oxydase in the most deeply coloured varieties, less in the less deeply coloured, and none at all in the white varieties. The white flowers of certain *Primula sinensis*, *Pisum sativum* and *Lathyrus odoratus* have all been shown to contain oxydases, and the white colour is attributed to the absence of chromogen. In the Mont Blanc Star, the distribution of oxydase again parallels that of pigment. One flower had irregular magenta flaked petals with one exception, this particular petal being of a uniform magenta colour. The latter petal gave a well marked oxydase reaction, the magenta patches on the others demonstrated a fair reaction, whilst the white portions did not respond to the test.

Similarly Sweet Williams were grown in full coloured, white and almost white varieties, the latter showing rosy dots or lines. The fully-coloured flowers responded definitely to the tests for the presence of oxydases, whilst the white flowers also gave a definite, but limited reaction—the white colour being probably due, as explained above, to the absence of chromogen. The white flowers with rosy dots showed oxydases only in the parts of the petals corresponding to the pigmented dots.

Space forbids a full discussion of the interesting subject of inhibitors, and it must suffice to say that reagents were discovered, such as hydrocyanic acid solution, and carbon dioxide solution, which destroyed the influence of these substances, and allowed the oxydases present to respond to the specific tests noted. The investigations upon white primulas, and specially cultivated varieties possessing white zones upon a blue ground, and on other white flowers, which are also known by breeding records to be in the class of dominant whites conclusively support the Mendelian hypothesis that the dominant white flowers contain no pigment, by reason of the presence of inhibitors of pigment formation. Inhibition is exercised upon the oxydases and not upon the processes which result in chromogen formation. Again, the inhibitors, as the name implies, do not destroy the oxydases, but merely interfere with their otherwise normal activity.

The recessive white varieties are those, noted above, which owe their lack of pigment to the absence of chromogen and not of oxydase.

Although the questions of localisation of oxydases, effects of light and darkness upon the development of oxydases and other vitally important matters cannot be discussed here, enough has been written to indicate the accuracy of the views of Armstrong and Keeble on the important *rôle* of oxydases (and peroxydases) in the formation of flower pigments. Much remains to be done before the full mechanism of the life processes of the plant responsible for colour development is revealed, but an important step forward has been made.

It only remains to be added that substantial confirmation of the views of Armstrong and Keeble has been forthcoming in the work of Atkins, as reported in the *Scientific Proceedings* of the Royal Dublin Society. This investigator has shown the presence of oxydases and inhibitors in the petals of the iris, the colours of which are due to the presence of a yellow plastic pigment and an anthocyan or anthocyans. The general distribution of enzyme and pigment in the iris resembles that in *Primula sinensis*.

THE ESTIMATION OF HYDROSULPHITE

Messrs. Brotherton and Co., Ltd., the makers of "Hydros" (sodium hydrosulphite), have sent us the following method of quantitative estimation which will be of interest to our readers.

The great advantage of the method described below is that the results are not affected by oxygen in the water used in the analysis. It must not be used for analysing Hydros containing decomposition products or soda ash.

Theory of the Process

A mixture of hydrogen iodide and hydrogen iodate in solution decomposes at once, giving free iodine :—

$$HIO_3+5HI=3I_2+3H_2O.$$

A mixture of potassium iodide and iodate can, therefore, be used to measure the hydrion of the bisulphite formed when "Hydros" oxidises potassium iodate :—

$$3Na_2S_2O_4+KIO_3+3H_2O=KI+6NaHSO_3.$$

$$6NaHSO_3+KIO_3+5KI=3I_2+3H_2O+3Na_2SO_3+3K_2SO_3.$$

The sulphite formed in the reactions above is oxidised by the free iodine :—

$$3Na_2SO_3+3K_2SO_3+6H_2O+6I_2=3Na_2SO_4+3K_2SO_4+12HI.$$

The hydrogen iodide, however, reacts with more of the iodide-iodate mixture and liberates a further six molecules of free iodine, so that the oxidation of the sulphites may be ignored :—

$$12HI+2KIO_3=2KI+6I_2+6H_2O.$$

The effect of "Hydros" on a mixture of potassium iodate and iodide is, therefore :—

$$3Na_2S_2O_4+4KIO_3+2KI=3I_2+3Na_2SO_4+3K_2SO_4.$$

The "Hydros" liberates its equivalent of iodine, and this iodine is measured by titration with standard thiosulphate.

Analytical Details

A litre flask is about half filled with water, and 6 gms. of potassium iodate, together with 10 gms. of potassium iodide, are added and dissolved. These quantities are approximate, but more rather than less should be used. 300 c.c. of *N*/10 thiosulphate is added from a pipette, and the flask filled to within about 50 c.c. of the mark. About 2 gms. of Hydros are accurately weighed in a weighing bottle, and poured into the flask through a perfectly dry funnel with a short wide neck. The flask is first shaken so as to impart a whirling motion to the liquid, then the flask and funnel are inclined to meet the weighing bottle, so that when the latter is completely inverted the funnel seals its mouth. This prevents the loss of any fine particles of Hydros in the form of a cloud. The flask is then filled up to the mark, stoppered and shaken till the Hydros is dissolved. The empty weighing bottle is reweighed, and the weight of the Hydros is determined by difference.

The excess of thiosulphate is measured by titration (100 c.c. at a time), with standard *N*/10 iodine.

Caution.—It is essential that in the weighing the Hydros be transferred from the sample bottle to the weighing bottle with a spatula, and not poured from one to the other. In the latter case a partial separation of the salt, generally used as a diluent, occurs, and the results are always too low, often by several units per cent.

Calculation

Weight of Hydros taken = 2·0136 gms.

Mean titration = 7·24 c.c.

N/10 iodine used to titrate complete litre = 10 × 7·24 = 72·4 c.c.

∴ *N*/10 thiosulphate left after dissolving Hydros = 72·4 c.c.

∴ *N*/10 thiosulphate absorbed in Hydros reaction = (300—72·4) = 227·6 c.c.

Molecular weight of Hydros = 174.

∴ Percentage of Hydros =

$$\frac{174}{2} \times \frac{227{\cdot}6 \times 100}{10{,}000 \times 2{\cdot}0136} = 98{\cdot}34\%$$

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on November 9, 1923, the President, Dr. E. F. Armstrong, F.R.S., in the Chair.

It was reported that the Council of the Chemical Society had approved the formation of the proposed Bureau of Chemical Abstracts and had nominated as its representatives on the Joint Committee Dr. Irvine Masson, Prof. G. T. Morgan, Prof. J. F. Thorpe, and Prof. W. P. Wynne. It had also approved the principles involved in the proposals for giving facilities to the members of each Society to acquire the publications of the other Society and for offering further inducements to chemists to join both Societies, and had remitted the discussion of details to a Committee of the Council.

It was decided to supply members of the Institution of Chemical Engineers who are not members of the Society of Chemical Industry with copies of *Chemistry and Industry* on certain terms, it being agreed that the Journal of the Society should become the official organ of the Institution.

It was decided to join in a scheme promoted by the Institute of Journalists for a Trade and Technical Journals Section at the British Empire Exhibition, 1924.

In furtherance of a scheme of co-operation between the Society of Chemical Industry and the Chemical Society, it was decided to supply Fellows of the latter Society with the Abstracts of the Society of Chemical Industry at the price of £1 10s. per annum, provided that a reciprocal arrangement be agreed to by the Chemical Society. It was further decided to supply Fellows of the Chemical Society with *Chemistry and Industry* at £1 per annum, with the additional provision that Fellows taking both the Abstracts and *Chemistry and Industry* shall pay the reduced annual sum of £2.

The Council agreed to the principle of the proposal that a reduction in the entrance fees should be made to anyone who shall join the two Societies.

Reports of various Committees of the Council were submitted and 15 new members (Home 12, Overseas 3) were elected.

It was intimated that at next meeting nominations would be received for the appointment of the Messel lecturer for 1924.

Prof. J. W. Hinchley was appointed one of the Society's representatives on the General Board of the National Physical Laboratory in room of Prof. F. G. Donnan who retires by seniority.

The date of the next Council meeting was fixed for Friday, December 14, 1923.

LIST OF MEMBERS ELECTED

November 9, 1923

Arkley, James, c/o Ritchie, 47, Polwarth Gardens, Edinburgh. Works Chemist.

Cory, Harold E. J., Kenwood, 10, Longlands Park Road, Sidcup, Kent. Technical Chemist.

Defries, Ralph, Sorbo Works, Woking. Technical Chemist.

Dewhurst, Milton, c/o White, Tomkins and Courage, Ltd., North Albert Works, Reigate, Surrey. Works Chemist.

Ferguson, Prof. John B., Chemical Building, University of Toronto, Toronto, Ont., Canada. Research Chemist.

Miller, Edgar C. L., The Library, Medical College of Virginia, Richmond, Virginia, U.S.A. Professor of Biochemistry.

Monsaroff, Boris, c/o Edwads and Edwards, Ltd., Leather Manufacturers, Woodbridge, Ont., Canada. Chemist.

Preston, James, 6, Dedridge Cottages, Mid-Calder, Scotland. Chemist.

Rowlands, John R., 25, Loughborough Road, West Bridgford, Nottingham. Chemist.

Silberrad, Charles A., Park House, Combe Martin, N. Devon. Indian Civil Service (retired).

Sparks, James, 6, Park Row, Greenwich, London, S.E. 10. Works Chemist.

Stevenson, Michael, c/o G. F. Merson, Ltd., St. John's Hill Works, Edinburgh. Technical Chemist.

Taylor, Colin K., 21, Cromwell Road, South Kensington, London, S.W. 7. Student.

Warner, Bertrand T., c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C. 3. Pharmaceutical Chemist.

Woolcott, Herbert, Messrs. H. and G. Simonds, Ltd., The Brewery, Reading. Chemist.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Vol. VIII is now in preparation and will be issued early in 1924. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members. Vol. I is out of print, but copies of Vols. II, III, IV, V, VI, and VII may be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d., and 7s. 6d., and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d. and 12s. 6d. respectively. If Vols. II, III, IV, V, VI, and VII are ordered at the same time as Vol. VIII, the set may be obtained by members for £2 2s. 6d., and by non-members for £3 15s. The appropriate remittance must accompany every order. The books are sent to purchasers post free.

CHEMICAL ENGINEERING GROUP

The first meeting for the session was held at the Chemical Industry Club, on November 16. Mr. J. Arthur Reavell occupied the chair, and Professor J. W. Hinchley gave a very interesting paper entitled "A New Source of Potash and its Industrial Exploitation."

Professor Hinchley pointed out that hitherto Germany had been the main source of potash supply, but since the war methods had been developed for obtaining potash from the mineral leucite, a rare mineral except along the line of Italian volcanoes, where it is characteristic of the lavas. The pure mineral contains 21·5 per cent. potash, 23·5 per cent. alumina and 55 per cent. of silica. Very large quantities of this mineral are found near the craters of extinct volcanoes which lie on a line extending from Orvieto to Naples, a distance of 186 miles. At present this mineral is being worked at the edge of the crater of the extinct Rocca Monfina volcano, where it is found in a very pure form. This deposit lies about 30 miles north of Naples, and about 12 miles from the seaport of Scauri. The land gradually declines from the edge of the crater to the coast and would therefore permit of easy transport of the material from the workings to the ship by a telpherage system.

It is estimated that the igneous rocks of this particular volcano, which cover an area of 80 square miles, contain 1,008,000,000 metric tons of potash and that in this deposit alone there is sufficient material to give at the present rate of consumption at least 500 years' world supply of potash, and that this could be obtained at no greater cost than that required for the working of the Stassfurt deposits. Over the whole range of these Italian volcanoes it is calculated that the leucitic lavas contain at least 8,786,000,000 metric tons of potash, making them the greatest accumulation of rich potash silica rocks known. Professor Hinchley visited these workings and found that the mineral occurs very near the earth's surface, and an examination of samples which he took at distances of half a mile apart reveals practically no difference in chemical content.

The development of this industry in Italy has been due to Baron Blanc, who, in spite of considerable opposition and difficulties, has been able to bring the processes to a state of commercial utility.

After mining the mineral is crushed into particles having an average size of one-sixteenth of an inch. During this stage a considerable amount of fine dust is produced, and this has been found useful as a fertiliser. The gangue contains a small amount of iron whose presence permits of its separation electromagnetically.

The separated mineral may be treated by many processes. In one process sulphuric acid is made to flow through a bed of leucite, the strength of the acid being gradually increased until the whole of the potash and alumina have been taken up. This treatment takes from two to three hours and is accompanied by a considerable rise in temperature. The saturated solution thus obtained is then allowed to cool from 75° C. and the potash alum crystallises out. If before crystallisation the saturated solution is passed through a fresh bed of leucite, any traces of iron present will be removed. The silica which is left in the treatment chamber is removed by an ejector and can be converted into sodium or potassium silicate by the simple treatment with caustic soda or caustic potash solution of suitable strength.

Another process consists in treating the bed of leucite with mother liquor and hydrochloric acid gas, when a solution of potassium and aluminium chloride is produced, which on cooling from 90° C., the temperature produced by the reaction, throws down the potash in the form of potassium chloride. The liquor is next treated with hydrochloric acid gas in the cold, when hydrated aluminium chloride is precipitated. The mother liquor after this precipitation is again used in the treatment of fresh leucite. The hydrated aluminium chloride passes into an inclined rotary kiln made of aluminium, where it is heated to 300° C. At this temperature hydrochloric acid gas is evolved, and this is carried back for further use on the fresh leucite in the extraction plant. Hydrated aluminium oxide is the solid product obtained from the kiln.

A third method, devised by Baron Blanc, assisted by M. Felix Jourdan, consists in treating the leucite with slaked lime in an autoclave for three hours at a pressure of about 200 lb. per square inch. The liquid produced is used in the similar treatment of a second batch of leucite and ultimately a 12 per cent. solution of caustic potash is obtained. The residue from the autoclaves has been found to make an excellent cement.

In conclusion, Professor Hinchley said he had introduced to the notice of the group a material which the chemical industry of this country cannot afford to neglect, and he hoped that before long he would be able to give the second part of the paper.

During the discussion, in which Messrs. Ormandy, Voelcker, Scholtz, Macnab, and Tripp took part, various aspects of the uses of the mineral and the products derived therefrom were discussed. Professor Hinchley replied to various points raised by the speakers and expressed his regret that time did not permit him to give a thorough description of the plants used, together with the balance sheets relating to their working. Mr. Reavell, in proposing a vote of thanks to Prof. Hinchley, suggested that such a paper should be given at a subsequent meeting of the group to be held at an early date.

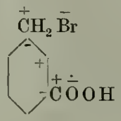
EDINBURGH AND EAST OF SCOTLAND SECTION

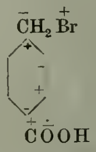
The second ordinary meeting took place on November 14 in the Hall of the Pharmaceutical Society, Edinburgh, Dr. H. E. Watt in the chair. This meeting was held under the scheme for co-operation with the Chemical Society. There was a good attendance of members and fellows of both societies.

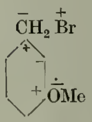
Mr. Teijiro Yabuta contributed a paper on "The Constitution of Kojic Acid, a pyrone derivative formed by *Asperigillus Oryzae* from carbohydrates." By the action of thionyl chloride on kojic acid, and subsequent reduction, the alcoholic hydroxyl is replaced by hydrogen, and a hydroxymethylpyrone results, *allo*maltol, isomeric both with maltol (Brand, *Ber.*, 1894, **27**, 806; Kiliani and Bazlen, *ibid.* p. 3115; Feuerstein *ibid.* 1901, **34**, 1804) and with *iso*-maltol (Backe, *Compt. Rend.*, 1910, **150**, 540, **151**, 78). *Allo*maltol can be transformed to 3 : 4 dihydroxy-6-picoline, which is a reduction product of comenamic acid (Bellmann, *J. prakt. Chem.*, 1884, **29**, 14). This shows that kojic acid is the alcohol corresponding to comenic acid, and is therefore 3-hydroxy-6-hydroxymethylpyrone, in accordance with the view previously expressed by the author on other grounds (*J. Chem. Soc. Tokyo*, 1916, **37**, 1185; A., 1922, i, 939). The relationship between kojic and comenic acids thus indirectly established, could not be demonstrated by direct interconversion in spite of numerous oxidation and reduction experiments. The instability of the pyrone nucleus, for instance, prevented the successful application of Rosenmund's method to the acid chloride of comenic acid.

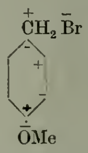
"The Reduction of the Mono-halogenated Phenols" was described in a paper by J. B. Shoesmith, M.Sc., and R. H. Slater, B.Sc., who applied the method employed to show that the halogen in *m*-methoxybenzyl bromide has acquired an induced positive polarity to the systematic investigation of the halogenated phenols. It was found, as was expected, that the order of reducibility would be *p*-Hal and *o*-Hal > *m*-Hal. The iodo compounds were reduced at 25° C. in glacial acetic acid solution by hydriodic acid; the bromo compounds were reduced at a higher temperature—namely, 78° C. The order in which the compounds reduce was $p\,\mathrm{I} > o\mathrm{I} > p\,\mathrm{Br} > o\mathrm{Br} > p\,\mathrm{Cl}$. The chloro compounds did not show much tendency to reduce. 4-Iodoresorcinol reduced rapidly under all conditions studied. Modified methods for preparing *m*-halogenated anilines were given.

In a paper on "Polarity Effects in the Isomeric ω-Bromo Toluic Acids," J. B. Shoesmith, M.Sc., and A. C. Hetherington, B.Sc., showed that reactivity in a molecule is mainly the result of (*a*) general polar influences, (*b*) spatial and steric influences, and (*c*) induced polar influences. In order to compare induced polarity effects in the aromatic series, effects due to (*a*) and (*b*) were minimised by the investigation of *m*- and *p*-isomerides. As a result of an application of the principle of induced alternate polarities to the case of the isomeric ω-bromo toluic acids it was anticipated that the ease of hydrolysis would be in the order $m > p$ and of reduction $p > m$, the reverse of such effects in the methoxybenzyl bromides.









The anticipated order was that discovered by experiment. The abnormal behaviour of the ortho isomeride is due to effects which were to be grouped under (*b*). The hydrolyses were carried out in aqueous alcoholic solution at 76° and the reduction in aqueous hydriodic acid—acetic acid solution at 110°.

SHAWINIGAN FALLS SECTION

A meeting was held at the Cascade Inn on October 15. Dr. F. W. Skirrow presided in the absence of Mr. R. A. Witherspoon, the chairman. A motion was passed continuing the officers elected in 1922-23 for another year.

The Shawinigan Section intends to hold monthly meetings during the winter, which will be of an informal nature and consist for the most part of the reading of papers by local men.

A very interesting paper by Mr. S. A. Wisdom was read, entitled "Carbon Black." Mr. Wisdom has been employed for some time by the Canada Carbide Company on research work in connexion with the manufacture of carbon black from acetylene, and is now operating a fair sized plant for its production in commercial quantity. On account of the patent situation, it was impossible to give much information on carbon black from acetylene, but the writer described in an interesting manner its manufacture in the ordinary way by incomplete combustion of natural gas. The manufacture of this valuable product permits the utilisation of natural-gas deposits in remote places which would be otherwise useless on account of the prohibitive cost of piping to industrial centres. The low cost of the plant allows it to be dismantled in case the well runs out, and moved to a new locality.

Carbon black has the property of extreme fineness, and possibly shows the greatest state of subdivision of any known solid. Its principal use is as a filler for rubber in automobile tyres, and to some extent in other kinds of rubber goods. It differs from other fillers in that it not only acts as a diluent but also imparts valuable properties to the rubber, making it wear longer, preventing hardening and cracking, and reducing its tendency to slip on a wet surface. On this account its use in pneumatic tyres had become almost universal.

TORONTO SECTION

The first meeting of the session was held on October 23, the attendance at the dinner being thirty-nine, and at the business meeting and address over a hundred. The local paint and varnish industry was well represented.

Mr. H. Green, of the New Jersey Zinc Co., spoke on " The Structure of Paint," illustrating his address by photomicrographs showing the nature of the particles and the manner in which they are suspended in paint. The many fine photomicrographs, which were taken with the aid of ultra-violet light, were much admired.

LIVERPOOL SECTION

The inaugural meeting of the session was held in the rooms of the Overseas League on November 16. The President of the Society, Dr. E. F. Armstrong, F.R.S., occupied the chair at the commencement of the proceedings, and referred to the deaths of Dr. E. K. Muspratt and Mr. H. S. Barker, votes of sympathy being passed in each case. Dr. J. T. Conroy was elected a trustee of the Hurter Memorial Fund in place of the late Mr. A. Carey. The chairman, Mr. Edwin Thompson, then delivered his address on " Our Water Supplies," which will appear in the forthcoming issue of *Chemistry and Industry*.

OTTAWA SECTION

There was an attendance of forty-two at the meeting held in the University Club on November 3, Dr. A. E. Macintyre in the chair. After the programme for the session had been outlined, Colonel Janson and Mr. R. T. Elworthy were appointed auditors, and the chairman then gave his address on " Education in Relation to Science."

There are two classes of learned men, he said : those who gather knowledge and seclude it, and those who disseminate it for the benefit of their fellows. The scientist belonged to the latter class. He did not appeal to the ordinary writer as a rule and his contributions were not literary art, but scientific prose containing accurate statements. Many scientists had been very able writers, and the inability of many persons to understand scientific authors was due to faulty education. Science demanded truth of its followers, and " about " or " near " did not satisfy the scientist. Reference was made to the statement of Premier Ferguson that our schools taught the youngsters to remember rather than think. Such a system would never develop a body of scientists with original and progressive ideas, and research of a high order could not be expected. In referring to recent criticism of American Universities, which appeared to be justified, it was pointed out that, although America produced over 85 per cent. of the world's output of non-benzenoid hydrocarbons, practically all the chemical research on these compounds had been performed by European chemists. The speaker emphatically stated that the text-books were playing too great a part in the education of the scientist to-day, and advised students to consult the original contributions. The value of reading was emphasized, but it was pointed out that literacy was not education, but merely an instrument by which it could be obtained. The mechanical and logical phases of memory were explained and the great value of imagination, one of the chief assets of the scientist, was pointed out. Whereas Capital and Labour generally considered that they alone created wealth, it was stated that their role was much inferior in its creation to that of mind. In closing his address, Dr. Macintyre urged chemists to apply to the study of science the injunction, " Read, mark, learn and inwardly digest."

Dr. Shutt thought that we were perhaps too ready to blame our educational system for the failure to develop more outstanding chemists, whereas the fundamental underlying real success was love and enthusiasm for the science of chemistry. Mr. Connor thought our educational system tended to develop too many men whom he referred to as " rough lumber." Mr. Peak suggested that a man might know so much as to be of no value to a firm. Any process of education, he thought, must develop reason which would give the individual pleasure in its use. Many people were not qualified by nature to acquire a scientific education. Mr. Hambly said that learning to digest our reading was most important, and that men of pre-eminence in science did not confine their reading to their particular subject. Dr. Atack referred to the attachment of some men to recipes and found that such men frequently were given appointments on the basis of this qualification. Journal reading, he thought, should be followed with caution in order not to clog the brain, but leave it free to think. He suggested " read as much as possible, forget most of it, but remember where to get it." He stressed the value of imagination, and thought that probably the accumulation of so much scientific knowledge in Britain was due to the fact that many chemists may exist in colleges there at research work on a mere pittance. Dr. Macintyre replied briefly to the points raised in discussion.

FORTHCOMING EVENTS

Nov. 26. The Royal Scottish Society of Arts, 117, George Street, Edinburgh, at 8 p.m. "The Development of the Supply of Electricity in Edinburgh and a Description of the New Generating Station," by F. A. Newington, M.Inst.C.E.

Nov. 27. Royal College of Science Chemical Society. Joint Meeting with the Royal School of Mines Metallurgical Society, The Royal College of Science, South Kensington, S.W. 7, at 5 p.m. "Metallurgical Processes in use at the Mint," by Sir T. Kirke Rose, D.Sc., A.R.S.M.

Nov. 27. The Optical Society, Imperial College of Science and Technology, South Kensington, S.W. 7, at 8 p.m. The 1923 Thomas Young Oration, by Dr. M. von Rohr (Jena).

Nov. 27. Society of Chemical Industry, *Birmingham and Midland Section.* Dinner to be held at The White Horse Hotel, Congreve Street, Birmingham, at 6 p.m., followed by Meeting in the University Buildings, Edmund Street, at 7.15 p.m. (1) "Acceleration of Vulcanisation by Xanthates, and the Influence of Metallic Oxides as Activators," by D. F. Twiss and F. Thomas. (2) "An Important Variable in Raw Rubber," by D. F. Twiss and F. B. Jones.

Nov. 28. Royal Microscopical Society, *The Industrial Applications Section*, 20, Hanover Square, W. 1, at 7.30 p.m. "The Characteristics of a Microscope for General and Special Purposes," by J. E. Barnard, F.Inst.P.; "The Application of the Microscope to Industrial Diseases," by Dr. S. H. Browning, L.R.C.P. "The Microscope in the Examination of Condensed Milk," by C. A. Newton.

Nov. 29. Institution of Mechanical Engineers, the Medical Theatre, Birmingham University. "Metal Rolling and the Influence of Cooling on Plastic Flow," by J. E. Fletcher.

Nov. 29. Institution of Mechanical Engineers, Engineers' Club, Albert Square, Manchester. Further Discussion on "Clyde Marine Oil-Engines," by Prof. A. L. Mellanby.

Nov. 30. Institution of Mechanical Engineers, Storey's Gate, London, S.W. 1, at 6 p.m. "Clyde Marine Oil-Engines," by A. L. Mellanby, D.Sc.

Nov. 30. The Manchester Literary and Philosophical Society, *Chemical Section*, at 7 p.m.

Nov. 30. The University of London, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science," by Prof. G. Dawes Hicks. (Lecture 5.)

Dec. 3. Birmingham University Chemical Society. Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. Lecture by A. Appleyard, M.Sc.

CHEMICAL SOCIETY

An ordinary meeting was held on Thursday, November 15, 1923, at 8 p.m., the President, Professor W. P. Wynne, F.R.S., being in the chair.

The President announced the complete constitution of the new Bureau of Chemical Abstracts to be as follows: Chairman, Professor J. C. Philip, F.R.S.; representatives of the Chemical Society, Dr. I. Masson, Professor G. T. Morgan, F.R.S., Professor J. F. Thorpe, F.R.S., and Professor W. P. Wynne, F.R.S.; representatives of the Society of Chemical Industry, Dr. E. F. Armstrong, F.R.S., Mr. Julian L. Baker, Mr. E. V. Evans, and Sir William J. Pope, F.R.S. The Bureau had already met, and was making arrangements for the issue of Abstracts for 1924 in two sections, (*a*) Pure Chemistry, and (*b*) Applied Chemistry, although for that year these sections would be practically of the same forms as those at present issued by the two societies. An agreement had also been reached whereby Members of the Society of Chemical Industry may procure the former section for 1924 for the sum of £1 10s., and Fellows of the Chemical Society (on application to the Society of Chemical Industry) can obtain *Chemistry and Industry* for 1924 for the sum of £1 and the latter section of Abstracts for £1 10s., or, alternatively, both these publications for 1924 for £2.

Fellows were also informed of a resolution of the Council to the effect that no publications for 1924 other than the *Journal* (containing thenceforth only the original papers communicated to the Society) would be sent to those Fellows who had not made application to the contrary by December 31, 1923. It was urged that replies to the circulars on this subject should be forwarded immediately, for only in the case of Fellows resident abroad could any extension of this period be considered.

In a further announcement, concerning the Harrison Memorial Prize, the President said that in accordance with the trust deed governing the Harrison Memorial Fund, a selection committee, consisting of the presidents of the Chemical Society, the Society of Chemical Industry, the Institute of Chemistry, and the Pharmaceutical Society, would shortly meet to consider the first award. The prize, which is of the value of about £150, is to be awarded to the chemist who, being of either sex, a natural-born British subject, and not at the time over thirty years of age, should be judged by the Selection Committee to have conducted during the previous five years the most meritorious and promising original investigations in any branch of pure or applied chemistry; the results of those investigations to have been published in a scientific periodical or periodicals. Provided that there is a candidate of sufficient distinction, an award would be made for the first time in December, 1923, and the President of the Chemical Society, on behalf of the Selection Committee, was prepared to receive applications, nominations, or information in connection therewith not later than Monday, December 10, 1923.

In the first paper, Dr. C. K. Ingold entered into the mathematical basis of the authors' views on the mutarotation of sugars, the position being summarised by the authors as follows :—

Ring-chain tautomerism. Dynamical evidence relating to the mutarotation of the sugars.
J. W. Baker, C. K. Ingold, and J. F. Thorpe.

FINAL proof of the incorrectness of the theory that water intervenes in the mutarotation of sugars—a theory suggested, for example, by Lowry, and accepted by most sugar chemists at the present time—can be obtained by studying the dynamics of the process. A paper on the mechanism of mutarotation, dealing not only with dynamical, but also with structural and other aspects of the problem, was read to the Society earlier in the year, and it was shown that the mutarotation-time curves have (*a*) a form ; (*b*) a spacing, on the mutarotation-time-concentration diagram, which are entirely at variance with the dynamical consequences of the intermediate-hydrate theory, but are in complete agreement with the hypothesis of ring-chain tautomerism, to which structural evidence also points. When this paper was read the criticism was raised that the derivation of the dynamical consequences of the hydrate theory was based on a fallacy. The authors do not accept this finding. The derivation given was admittedly an approximate one and was incorporated in the paper on account of its simplicity. However, private correspondence having failed to produce agreement on this point, they have now decided to present to the Society the complete mathematical analysis on which their conclusions were based.

Professor T. M. Lowry, F.R.S., said that he had not the slightest difficulty in accepting the suggestion that mutarotation in the sugar series might be due to a reversible acetal condensation. He had himself in 1899 (*T.*, 75, 213) been the first to suggest that this mutarotation might be due to isomeric change, instead of to hydration (Emil Fischer's theory) or to the breaking up of a complex " crystal molecule " as suggested by still earlier workers. Further, he had in 1903 (*T.*, 83, 1316) and, again, in 1904 (*T.*, **85**, 1569) made the concrete suggestion that the intermediate form in the interconversion of the stereoisomeric glucosidic forms of the sugars was probably " the aldehydic form of the sugar or its hydrate." The former of these two suggestions had been adopted by the authors, and to this the speaker raised no objection whatever.

He was, however, completely at variance with them in their assertion that water does not intervene in the mutarotation of the sugars, since mutarotation in aqueous solutions is approximately 200 times more rapid than in the cases studied by them. The authors' calculations had, on the contrary, led them to conclude that the velocity change should be independent of the concentration of water in the solvent, not only when the water was present in mere traces, but also over a wider range. This result was obviously incorrect for solutions containing much water ; and, at the other extreme, if Bakerian dryness could be obtained in a solution it would probably likewise be incorrect, since facile isomeric changes, such as those of nitrocamphor and ethyl acetoacetate, had been arrested by careful purification, and there was no reason to suppose that the sugars would behave differently. There was also evidence from measurements of solubility (*T.*, **85**, 1581) which suggested very strongly that the intermediate compound was increased in quantity by the addition of water, and was therefore probably hydrated. Whilst, therefore, the reversible acetal condensation provided a possible mechanism for isomeric change in the sugar series, there was no experimental basis whatever for the assertion that it was the only mechanism that was possible even when large quantities of water were present

Dr. T. Slater Price confessed that he had been the innocent cause of the " heavy gunfire " of mathematics to which they had been subjected; despite correspondence with Dr. Ingold he had been unable to agree that the conclusions which had been originally drawn rested on an unassailable mathematical foundation. It was, however, manifestly impossible to criticise " on sight " an analysis (although this led to the same conclusions) which had taken some weeks to evolve, and in regard to it he had an open mind.

Dr. H. Weiss, Professors W. N. Haworth, H. E. Armstrong, F.R.S., and J. F. Thorpe, F.R.S., contributed to the discussion.

Dr. Ingold, in reply, said that nothing in the experiments affected the practical certainty, that no reaction would take place in complete absence of water. All that had been shown was that if water plays a part, it does not act *by adding on and splitting off again.* The mode of action of catalysis by water was unknown, but he considered that no special catalysis of this kind superimposed on the dynamical consequences of the hydrate theory could reinstate the latter, because this would here involve the incorrect assumption of negative catalytic influence. Professor Lowry had suggested possible complications arising from a competition between the carbonyl group of the second solvent (ethyl acetate in one set of experiments) and that of the sugar, for the added water. Apart from the fact that the same effects were observed in solvents which do not possess a carbonyl group, such a condition would cause the velocity constant to decrease with decreasing water content more rapidly than would correspond with direct proportionality, instead of less rapidly as suggested by Professor Lowry.

The evidence from solubility measurements that there is an intermediate substance between α- and β-sugar was of interest, but such measurements did not distinguish between a hydrate and an isomeric aldo-form.

The speaker disclaimed any suggestion that the authors had originated a theory of mutarotation, the credit for the ring chain tautomerism theory being ascribed entirely to Jacobsen and Stelzner; and he gathered, from what had been said, that Professor Lowry still adheres to his 1903 paper, despite his 1899 paper.

The following are abstracts of investigations which were described by Dr. G. Shearer:—

An X-ray investigation of certain organic esters, and other long chain compounds. G. Shearer.

This work extends that of Müller on the normal fatty acids (*T.*, 1923, **123**, 2043). By means of an accurate X-ray reflexion method, measurements have been made upon solid crystalline films of methyl, ethyl, octyl, and cetyl palmitates, of methyl and ethyl stearates, of *p*-hexadecylphenol, *p*-octadecylphenol, and of octadecylbenzene. As in Müller's experiments, very good reflexions are obtained from what are probably the crystal cleavage-planes, the distances or "spacings" between which can thus be determined. These are given in the paper. The cleavage spacings of the palmitic esters increase regularly with the number of carbon atoms in the alkyl group; and the increment per carbon atom of the chemical formula is the same for these esters as for the two stearates studied, namely, 1·22 Å.U. for each CH_2 of the *alkyl* radicle. When the palmitic and stearic esters of a given alkyl radicle are compared, the increment in spacing per CH_2 of the *acid* radicle is found to be 1·0. This figure agrees with Müller's value of 2·0 in the case of the free fatty acids, if his assumption is adopted that there are two molecules end-to-end between the cleavage planes of the free acids, and if only one be allowed in the cell of the esters. The accepted and independently measured "diameter" of the carbon atom is 1·5 Å.U. In order that chains, built of atoms of this diameter, shall have the perpendicular distance of 1·22 Å.U. between contiguous carbon atoms, which is shown to prevail in the alkyl chains, it is necessary, either that the chains shall be tilted at an angle to the cleavage planes, or else, if their lengths are perpendicular to the planes, that the carbon atoms should be linked spirally or zig-zag. On the latter idea, the angle between neighbouring carbon atoms would be given by $\sin \theta/2 = 1{\cdot}22/1{\cdot}50$, or $\theta = 109{\cdot}3^\circ$; which agrees with the tetrahedral angle. In the alkyl phenols and alkyl benzene, it seems that there is a pair of molecules, end-on, in the cell; in this case the increment due to ·O· is of the expected order, as is that due to $\cdot CH_2\cdot$; but the exact value of the latter is not yet decided upon. It is possible to calculate with fair accuracy the observed cleavage spacings from the molecular formulæ, placing one or else two molecules between successive cleavage planes as already indicated, by using the independently-known "atomic radii," and by allowing that an acid radicle increases by 1·0 Å.U., an alkyl radicle by 1·22 Å.U., per CH_2 group; where necessary, W. H. Bragg's value for the dimensions of the benzene ring is also used.

Further X-ray measurements of long chain compounds, and a note on their interpretation. Alex. Müller and G. Shearer.

Data are first given for the cleavage spacings of undecylic, pentadecylic, and margaric acids; for oleic, elaidic, and *iso*-oleic acids; and for erucic and brassidic acids. As in the foregoing paper and in that of Müller (*loc. cit.*), two other observed sets of spacings are also recorded, which apparently correspond with the cross-sections of the molecules, since they are practically constant for all the substances concerned. The cleavage spacings of the "odd" fatty acids are nearly equal to those which would be interpolated from the spacings of the "even" members, but slightly exceed them.

A systematic exposition is given of the conclusions which can legitimately be drawn from these experiments. On the assumption that the tetrahedral angle is conserved, it is shown that, theoretically, only a very limited number of different types of periodic chain can be constructed. Two of these chains show average increases per CH_2 group, which agree excellently with the observed increases in the alkyl and acid radicles respectively, when the "diameter" of the carbon atom is given its generally accepted value. Other explanations are considered but are not found satisfactory. The interpretation is shown to be in agreement with the slightly anomalous lengths of the "odd" free acid molecules. In the case of stereoisomers of a given unsaturated acid, the observed differences, when expressed in terms of the two types of chain, lead to the inference of cis-trans isomerism, and point to a definite attribution of structure as between the two isomers. The differences between corresponding saturated and unsaturated "straight-chain" acids are discussed.

Sir W. H. Bragg, F.R.S., offered his congratulations to the authors, and called attention to the parallel results which were being obtained relative to the length of the molecule and the structure of the chain by investigations of films of various organic compounds on water. The assumption that the general line of the molecule is perpendicular to the surface was justified by the results. If the carbon tetrahedral angle was real, the number of types of chain admissible was limited to three, one of which would lead to optical activity; the others were those which now received experimental justification.

Professor Armstrong's question whether any considerable interval was observed before the stable condition was reached was answered in the negative.

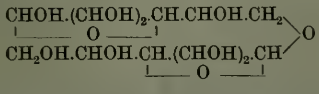
Mr. N. K. Adam observed that Dr. Shearer's results showed the existence of two packings of different densities, and consequently no safe deductions as to the length of a molecule, involving an assumption that the film-density equals the liquid density, could be made from measurements of cross-section alone. In some recent experiments no substantial difference could be detected between the cross-sectional areas of alcoholic and acidic chains in surface films; lengthening the chains by one or more CH_2 groups increased the lateral attraction between the chains by the same amount in each type of chain. There seemed to be no reason, however, why the two types of chain suggested should not have nearly identical properties in these two respects. From a consideration of regularities in the melting points, the speaker had already predicted, for the crystals of fatty acids and their esters, a structure which was practically the same as that evolved from X-ray measurements.

Dr. A. Müller said that much further work was requisite in order to study the effect of various groups. The consideration of compounds of the simpler types was meanwhile being undertaken.

Professor W. N. Haworth then gave an account of some further investigations in the domain of sugar-chemistry :—

The constitution of the disaccharides. Part IX. Gentiobiose. Its identity with amygdalin biose. W. N. Haworth and B. Wylam.

On hydrolysis of completely methylated gentiobiose, two partly methylated glucoses were isolated, which were identified as 2.3.5.6-tetramethylglucose and 2.3.5 trimethylglucose of the normal type. It follows, therefore, that gentiobiose possesses the same constitution as both maltose and amygdalin biose. Moreover, since the latter sugar contains a β-linking uniting the two glucose residues exactly as does gentiobiose it is now demonstrated that gentiobiose is the disaccharide which occurs in amygdalin, and is to be represented by the following structure :—

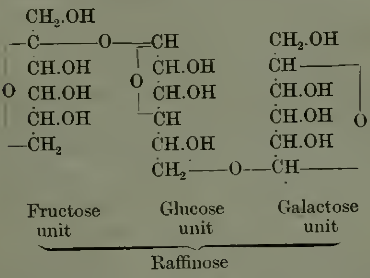


$$\begin{array}{l} \underbrace{\text{CHOH.(CHOH)}_2\text{.CH}}_{\text{O}}\text{.CHOH.CH}_2 \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad > \text{O} \\ \text{CH}_2\text{OH.CHOH.}\underbrace{\text{CH.(CHOH)}_2\text{.CH}}_{\text{O}} \end{array}$$

Synthetic work which is in progress, directed to the synthesis of amygdalin, has also confirmed this result. The constitutional formula for the trisaccharide gentianose follows from this investigation.

The constitution of raffinose. W. N. Haworth, E. L. Hirst, and D. A. Ruell.

Raffinose, prepared from cotton seed meal, gave rise on methylation to hendecamethyl raffinose distilling at 238° C. /0·02 mm., and showing $[\alpha]_D = +128°$. Hydrolysis of this product with one per cent. hydrochloric acid at 90° C., led to the isolation of three partly methylated hexoses, which were recognised respectively as tetramethyl γ-fructose identical with that isolated from methylated sucrose, as 2.3.5-trimethyl glucose (butylene oxidic), which gave a crystalline methylglucoside melting at 94° C., and as a tetramethyl galactose, which gave a crystalline anilide identical with that prepared from methylated lactose. From a constitutional study of these cleavage products the following structural formula for raffinose is deduced :—



It would therefore appear that the constitution of melibiose is to be represented by a formula in which the glucose unit, through the hydroxyl group attached to its terminal carbon atom 6, is linked with the reducing group of galactose.

INSTITUTION OF CHEMICAL ENGINEERS

A meeting was held at the Engineers' Club, Piccadilly, W. 1, on November 14, Sir Arthur Duckham, K.B.E., the President, in the Chair. The President, in commenting on the value of formal meetings, said that the Council had not yet been able to complete arrangements for future meetings, whether formal or informal; there would, of course, be a formal annual meeting next year.

Mr. M. B. Donald then gave a short account of the paper by himself and Mr. C. W. Tyson, entitled "A Study of the Absorption Tower." In the preparation of sulphite liquor for use in the pulp industry, milk of lime is converted into bisulphites in a plate absorption tower, the additional sulphur dioxide being added in a tile tower. The object of the research was to ascertain the factors of the design of these towers and to determine the factors underlying the absorption of gases by liquids on a plant scale. The results of the investigation have already been published in the *Transactions* of the Institution of Chemical Engineers. An interesting discussion followed, the speakers including Prof. J. W. Hinchley, Sir A. Duckham, Prof. Williams and Messrs. T. C. Broomfield, Finlayson, Swinden and West.

The second paper, "A Study of the Conditions of Constant Rate of Flow in Filter Presses," by M. B. Donald and R. D. Hunneman, which was read in abstract by Mr. Donald, has also been published in the *Transactions* of the Institution. Mr. A. E. Alliott then raised a number of questions to which Mr. Donald replied.

THE CHEMICAL INDUSTRY CLUB

The Fifth Annual Meeting of the Chemical Industry Club was held in the Club Rooms, at 2, Whitehall Court, on Monday, November 12, Mr. A. Gordon Craig presiding. After the Report of the Executive Committee and the Accounts had been passed, Dr. W. R. Ormandy moved the election of Mr. J. Miller Jones and Dr. E. H. Tripp to the posts of honorary treasurer and honorary secretary, respectively. These appointments were approved unanimously, and hearty votes of thanks were accorded to the retiring officers, Mr. C. J. Goodwin and Mr. H. E. Coley. The Rules, as revised during the past year, mainly through the labours of Mr. W. Cullen and Dr. A. Rule, were approved. Under the new regulations the Club is empowered to elect a President and a Vice-president, to hold office for a period not exceeding two years, and Sir William Pope and Prof. W. R. E. Hodgkinson were elected to fill these positions. A vote of thanks to Mr. Craig for his services as Chairman of the Executive Committee during the past two years was passed with acclamation. Subsequently to the meeting the Executive Committee appointed Mr. H. E. Coley to be its chairman for the ensuing year.

The speakers at the Annual Dinner of the Club, to be held in the Connaught Rooms, W.C., on Monday, November 26, will include Sir Lionel Phillips, Sir Arthur Duckham, Mr. F. W. Harbord, and probably Sir John Cadman. A large gathering is already assured, and those who still require tickets (15s. each, inclusive of cocktails and tips) should apply without delay to the Secretary at 2, Whitehall Court.

At a recent meeting the Société Pathé Cinema announced that its factory for the manufacture of cinematograph films was now in working order in England.

ROYAL MICROSCOPICAL SOCIETY.

A meeting of the Industrial Applications Section was held on October 24, the president, Prof. F. J. Cheshire, in the chair.

Dr. Marie Stopes read a paper on "The Microscope as applied to Recent Coal Research," in which she gave a brief historical review of the application of the microscope to research on the intimate structure of coal, pointing out that the early workers like Dawson and Huxley tended to treat "coal" as if it were a uniform substance. But recent work had shown the importance of the physical, chemical and microscopic differences between the finer bands, even in the same lump of coal, where only a few millimetres apart one zone might show a preponderance of spores and another a preponderance of leaf or stem tissue, and another not any structure at all but a uniform glue-like texture. A brief summary of the rationale of this was given, based on the paper read before the Royal Society and published in 1919, when detailed descriptions, and diagnoses of fusain, durain, clarain and vitrain were first given. These four main types composing bituminous coal had since been the subject of a great deal of detailed chemical, physical and microscopical work. Recent very interesting work by Prof. Seyler had shown similar zones in anthracite by a method of examination by reflected light. Whilst we were still far from a really detailed knowledge of the actual nature of the ultimate compounds composing ordinary coal, this microscopic work in conjunction with detailed chemical research was actively being pursued and leading to very suggestive results.

The paper was followed by the first of a series of lecture demonstrations on the manipulation of the microscope. The first lecture dealt with the work-table of a microscopist who requires an ever-ready equipment; illuminants suitable for various classes of work were discussed.

PHYSICAL SOCIETY

The following papers were read at a recent meeting of the Physical Society:—

Dr. H. Chatley, D.Sc., described further work on cohesion, from which he concluded that the Born-Landé expression agrees with a linear expansion before rupture in solids of about 12 per cent. in any direction which conforms moderately well to the results of uni-directional tension experiments with non-plastic materials. The space-rate of change of compressibility deduced from the same expression was found to agree very fairly well with the experimental results obtained with fluids under high pressures.

Dr. E. A. Owen, M.A., and G. D. Preston, B.A., presented a paper on the "X-ray Analysis of Solid Solutions." The results obtained show that in solid solutions of copper-aluminium,

aluminium-magnesium and copper-nickel the solute atom replaces an atom in the lattice of the solvent. This substitution of atoms is accompanied in the cases examined by a distortion of the lattice, but the type of the lattice remains unaltered throughout a series of solid solutions until the limit of solid solubility is reached. In none of the cases examined was it found that the interstitial arrangement of atoms occurred, with the possible exception of copper-aluminium alloys rich in aluminium. In these alloys the atomic percentage of copper was so small that the accuracy of measurement was not sufficient to decide definitely between the two possible atomic arrangements. In the lattice suggested for the inter-metallic compound $CuAl_2$, the centres of the aluminium atoms are separated by 2·40A, which is smaller than the diameter of the atom (2·86A) deduced from the structure of pure aluminium. Similarly, the distance between the copper atoms, which is also 2.40A, is smaller than the atomic diameter of copper (2.54A) obtained from the pure element. A possible explanation of these results is that the atoms share electrons and are brought closer together than would otherwise be the case.

In a paper on "The Fine Structure of Some Sodium Salts of the Fatty Acids in Soap Curds," by S. H. Piper, B.Sc., and E. N. Grindley, B.Sc., experiments (not yet complete) were described which were originally undertaken to determine by X-ray methods whether the fibres observable in certain soap curds were crystalline in nature. X-ray photographs of certain sodium salts of the fatty acids (soap curds) were found to show lines due to reflections from planes with very wide spacings of the order 40 A.U. These planar spacings increase uniformly with the number of CH_2 groups in the molecule, indicating an effective length of 1·25 A.U. for the CH_2 group. These and other lines can be accounted for by assuming that the curds are in the smectic state described by Friedel.

A method of measuring the surface tension of a small quantity of liquid was described by Dr. A. Ferguson, M.A. If a small quantity of liquid—1 cb. millimetre or less—be placed in a vertical capillary tube, its surface tension may be ascertained by applying pressure to the upper end of the tube, and measuring the pressure necessary to force the liquid into such a position that the meniscus at the lower end of the tube is plane. Interfacial tensions may also be determined in this way.

S. P. Sharples, whose death at Cambridge, Mass., is reported, was professor of chemistry at Boston Dental College from 1875 to 1893 and did much work as a consultant. He was a member of the Society of Chemical Industry.

CORRESPONDENCE

ACTIVATED CARBON v. SILICA GEL

Sir,—In the issue of your *Journal* of September 7, 1923, under the caption, "The Use of Solid Absorbents," Mr. Rex Furness makes certain surprising statements as to the comparative merits of silica gel and activated carbon as gas absorbents for benzol and similar solvent recovery operations. These statements are explicable only upon the assumption that the disparity which existed during the war between the quality of British or Continental and American military adsorbent carbons—a disparity inherent in the processes of manufacture—still continues to characterise the commercial carbons made here and abroad. In other words, European and American activated carbons cannot be considered technical equivalents.

This explanation if true, however, scarcely justifies the reasoning by which Mr. Furness arrives at the astonishing conclusion that activated carbon is so inferior to silica gel as an industrial vapour adsorbent that its serious consideration is quite unnecessary.

He states that "The development of gas-absorption carbons or charcoals . . . . particularly during the later years of the world war has been paralleled only by the development of highly absorptive inorganic 'gels' such as silica gel . . . . and other compounds such as ferric hydroxide gel. The high efficiency naturally demanded when active carbon had to be used as a protection against toxic gases in the field has been equalled and even surpassed by that of silica gel and other inorganic absorbents."

The casual reader would naturally infer from these paragraphs that carbon and silica gel were twin brothers distinguishable only by the slight superiority of the latter. After this he would probably be surprised to hear that both silica gel and ferric hydroxide gel were and are absolutely worthless for military uses, whilst carbon is of irreplaceable value. In the face of such facts Mr. Furness's statement that "The phenomena of absorption are identical in all cases from a practical point of view," is evidently mistaken. From a practical point of view the difference in behaviour of the two absorbents is very great and directly affects such industrial applications as benzol recovery.

The basis of their difference in behaviour is that the powers of selective adsorption of carbon and silica gel are diametrically opposite in character. Silica gel is hydrophilic or selective for water vapour, whereas carbon is non-selective for water but possesses a very high "specific capacity" or selectivity for hydrocarbons and hydrocarbon derivatives, which latter include practically all of the ordinary solvents and vapours of industrial importance. If shaken into a mixture of water and benzol, active carbon will absorb the benzol and reject the water. Silica gel does the reverse. The efficiency of the latter therefore decreases enormously in the presence of water vapour, and a pre-requisite of its employment is a careful drying of the gases. On the other hand, the capacity of the activated carbon for absorbing benzol is practically independent of the presence of water vapour in the gases, or even of the saturation of the carbon itself with water.

The rate of absorption by wet carbon falls off somewhat, but this is easily compensated by proper design of the adsorbers. Thus, after steam distilling the solvent from a carbon absorber, drying of the carbon is quite unnecessary. These matters are discussed in detail in two recent papers from our Laboratories, one presented before the American Institute of Chemical Engineers in June of this year, entitled "The Properties of Activated Carbon which Determine its Industrial Applications," which will appear in full in the December issue of the *Journal of Industrial and Engineering Chemistry*, and the other by Dr. Ray in *Chemical and Metallurgical Engineering* of August 27, entitled "Industrial Adsorption of Gas and Vapour with Activated Carbon."

Mr. Furness specifically refers to the greater density and "space-time" absorptive capacity of silica gel in comparison with activated carbon. These comparisons are true only of low-density wood charcoal or of imperfect activation such as is obtained by the processes of simple calcination, with or without mineral additions. They do not apply to highly activated carbons having the correct porosity or "critical" apparent density corresponding to the maximum surface and consequently to the maximum adsorbent capacity per *unit volume* of carbon granules. The methods of preparing active carbons developed by the writer for the Chemical Warfare Service represent the practical utilisation of this principle of critical densities by applying a two-stage oxidation process to chars so prepared or selected as to have an initial density considerably above the critical density, which is then approximated, first, by a primary "selective" or "activating" oxidation which eliminates the adsorbed hydrocarbons and gives the unsaturated surface lattice or matrix characteristic of active carbon; and, second, by a stage of "limited" oxidation the sole purpose of which is to bring the carbon granules to the correct porosity or density for maximum surface exposure per unit volume. Ordinary wood chars are already below the critical density (about 0·41 for 8—10 mesh granules) before activation, and hence are inherently incapable of yielding the highest gas adsorbent carbons having regard to the "space-time" factor. It is also obvious that to obtain the best mechanical properties the density should be the highest possible consistent with effective surface exposure.

Gas adsorbent carbons for industrial use are manufactured in the United States exclusively by processes embodying these principles, as fully discussed in the papers referred to above.

Commercial activated carbons such as are made in this manner for gasoline recovery installations and the like are not approached in intrinsic adsorptive capacity either per unit weight or per unit volume of adsorbent by any inorganic gels so far placed upon the market.

Enough has been said, therefore, to show that activated carbon cannot be safely left out of the discussion when considering benzol and other solvent recovery problems—a suggestion which even Mr. Furness found impracticable, since he was subsequently reduced to the necessity of taking data from experiments and installations employing carbon in order to show how good silica gel would have been if it had been used.—I am, Sir, etc.,

N. K. Chaney,

Union Carbide and Carbon Research Laboratories, Inc.
New York,
Nov. 8, 1923

P.S.—You may find another paper of Dr. Ray's entitled the "Manufacture of Activated Carbon" (*Chem. and Met. Eng.*, June 4, 1923) of some interest in this connexion.

ELLIS'S PRACTICAL BACTERIOLOGY FOR CHEMICAL STUDENTS

Sir,—If your columns are still open to the continuance of this correspondence, I shall be glad of the opportunity of replying to Dr. Renshaw's reply. In the first place, I did not wish to attribute to him any personal ill-feeling: that under the circumstances was quite out of the question. But when the condemnation of a book is supported by ridiculous details which, when challenged, are found to be built on sand, one may reasonably suspect rather a malicious habit of mind. Were this the only ground for replying, I should not have deemed it worth while. What does make it worth while is the need of rectifying the distorted and ill-balanced point of view which underlies Dr. Renshaw's remarks. My experience in teaching bacteriology to chemical students has been consistently uniform. Whilst they are expert at manipulative details, they are at first hopelessly at sea whenever the biological side is presented to their notice. This of necessity must be the case from the very nature of their training and does not impute the existence of a defect in this training. But bacteria are plants and unless their study is conducted on biological lines, and the fundamentals laid down as they would be in a biology class, bacteriology will become to the chemist the purely empirical study which it is to the average medical student. In essentials it comes to this, that I am blamed for not sufficiently decorating the walls, and have busied myself with laying down the foundations. Why should I teach chemists matters like H-ion concentration which they are far more competent to tackle than I am? It is not for me to write a book of chemistry with a bacteriological bias. My business is to indicate how best to approach a biological subject with the best chances of success. Once the fundamentals are grasped, the chemist can himself undertake the building up and make the subject adequate to the purpose of his researches. Dr. Renshaw himself knows, and practically admits, that the bacteriological training of the medical student is very inadequate. His whole attitude seems to imply that he would desire the chemist to travel along the same empirical path. The educationalist is not yet born in him. He condemns the use of *Bac. megatherium* because this will not make a bacteriologist out of the chemist. This by the way is different from his former attitude that "this organism was not of much use in the laboratory." The change, however, shows that whilst he disagrees, he understands my point of view—and I am thankful for small mercies. I state, with the knowledge born of experience, that in taking the chemist along the line that he would be taken as a matter of course in a biology class, I can make him as near a bacteriologist as is possible in a 4s. 6d. book by heading the way I have taken. I should have been grateful had the matter at the start been taken up on this issue.

Not only has he misunderstood my object in general, he has brought forward statements of detail which are equally absurd. He cannot distinguish between the use of gelatin in a specialised medical laboratory, and its educative use as an instrument for showing students how one microbe differs from another. I wonder if Dr. Renshaw is aware, as a bacteriologist, of the fact that about 2000 different species of bacteria have been described over and above the fifty pathogenic organisms that come within the scope of the medical bacteriologist's work. The works chemist will be concerned with one or other of the 2000 and not, or very seldom, with the fifty pathogenic organisms. It is obvious that Dr. Renshaw is referring to the fifty pathogenics only when he states that gelatin media are useless for the cultivation of bacteria. Surely Dr. Renshaw is permitting himself a little extravagance when he refers to the "life and death responsibilities dependent upon accurate diagnosis in human bacteriology." The works chemist does not propose to specialise in human bacteriology. Is it not possible for your reviewer to turn his back on the medical laboratory? And if the *preliminary* training in bacteriology is a life and death matter, I tremble to think of the responsibility of those who drew up syllabuses in bacteriology for the medical student and even—greatly daring—for the D.P.H. My own work has demanded a very close attention to technique to have got the results which I did obtain, and I would be the last to advocate loose technique; but one does not condemn a 4s. 6d. book on general chemistry merely because it does not contain information which would be useful to a research chemist at Nobel's. Neither does one condemn the insertion of an easy exercise in chemistry because there are others which are more difficult.
—I am, Sir, etc., David Ellis

Royal Technical College,
Glasgow

THE DISCOVERER OF ZYMASE

Sir,—In the review of Prof. Harden's book on "Alcoholic Fermentation," Prof. A. R. Ling states: "Soon after the discovery of zymase by E. Buchner in 1897. . . ." Now is it not a fact that zymase was discovered by Béchamp, as he stated in a memoir on fermentation by organised ferments which he read before the Academy of Science on April 4, 1864?

Your reviewer continues to give a list of great names, including Pasteur, Buchner, etc., but no reference is made to Béchamp. Is this purely an oversight?—I am, Sir, etc.,

Eccles Chas. W. Duckworth
November 17, 1923

THE CHEMIST AND THE PUBLIC

Sir,—Referring to recent correspondence on this topic, would not the most practicable method of educating the public be for chemists to cooperate in federating all the isolated scientific and intellectual societies up and down the country and linking them to the Universities or to the British Association?

Already the British Association has five such federations linked to it—viz.:—The South-Eastern Union of Scientific Societies, the South-Western Naturalists Union, the Yorkshire Naturalists Union, the Joint Committee of Scientific Societies, Liverpool, and the Association of Science and Art Societies, Gloucester. If this movement were encouraged and became general, not only would public opinion be profoundly affected, but a political lever created capable of moving any Government, as such an organisation would influence a great number of votes, and might even adopt candidates for parliamentary honours. The time appears ripe for such a movement. Are chemists prepared to act?—I am, Sir, etc.,

Gloucester, Cornilius A. Hawkes
Nov. 19, 1923

August Merz, of Heller and Merz, has been elected chairman of the dyestuffs section of the Synthetic Chemical Manufacturers' Association, in the place of the late Fred Signer.

REVIEWS

Blanchîment, Teinture, Impression, Apprets. *By* P. Lederlin. *Edited by* Prof. C. Matignon. *Pp.* 543. *Paris: J. B. Bailliere,* 1923. *Price, paper,* 45 *frs.; bound,* 55 *frs.*

The facility of the French language for condensed statement is very well illustrated by this work, which sets out to give a practical account of the bleaching, dyeing and printing of cotton, in all forms, within the space of some 500 pages, many of which are taken up by diagrams and illustrations of machinery. Even with this facility of language at his command, and with a special gift for systematic arrangement of his material, the author has been able to treat many portions of his subject only in a very cursory manner. The practical man will find very little guidance in the portions devoted to machinery, and many of the descriptions of processes are merely such outlines as might be given to a visitor to a works in explanation of the machinery and activities he would see. On the other hand, the chemist in dye, bleach or print-works will find much to admire in the concise presentation of the facts and the lucid way in which the logical connexion between the chemical and physical properties of the materials used and the effects of their use in the works is made clear. The portions of the book which deal with the precautions to be taken to avoid damages and methods of tracing damages to their source (at any rate, when a chemical source is in question) are written and arranged with admirable orderliness and precision, and though, unfortunately, the phenomena which are observed in works do not always illustrate the same logical simplicity, yet the author's methodical review does afford a means and plan by which the main factors concerned can be rapidly reviewed. The section on dyeing, after a brief summary of the chemistry of dyestuffs, groups them according to their properties of fastness and suitability to particular goods. The account of the application of these dyes is arranged according to colour. The convenience of this arrangement as a guide to selecting a dyestuff for a particular purpose is obvious.

The book can be warmly recommended to all who have control of operations in these industries, or are preparing themselves for such a position, on account of the methodical arrangement into which it will bring their knowledge. It is refreshing, after reading the works of English and German authors on these subjects, to come into contact with a mind which has a different quality, eschews all that is tentative or speculative and avoids all padding, and though the book is far from comprehensive and often meagre in its descriptive parts, it is unusually concise, lucid and logical for a work of this kind. Benjamin Leech

Tables Annuelles de Constantes, etc., Art de l'Ingénieur et Métallurgie. *By* L. Descroix. *Pp.* 154. *Gauthier-Villars et Cie., Paris.* 1922. *Price* 40 *francs.*

There has been a considerable development during the last few years of the systematic study of metals and alloys, particularly from the point of view of their physical and mechanical properties. Innumerable measurements, the results of which are hidden away and difficult of access, remain unknown to a majority of technicians. The International Committee of the Annual Tables of Constants of Chemistry, Physics and Technology has been charged, as is well known, to collect all such information, both scientific and technical, and has thus been placed in a position to provide in the book mentioned above a great quantity of information which it is impossible to procure elsewhere.

The editor of this book, containing abstracts for the years 1913 to 1916 inclusive, was well prepared to undertake this work because of his work in connexion with the Revue de Métallurgie. In addition to metallurgy, this volume contains facts of every sort concerning the art of engineering. It contains information concerning the different building materials, textiles, fabrics, industrial products, machines, fuels, refractories, and so on. On the metallurgical side, besides mechanical constants, it contains valuable information relating to the constitutions of alloys, their physical and electrical properties, corrosion, and so forth. The "Tables Annuelles de Constantes" should become an invaluable aid for collecting and making known the new experimental data concerning engineering and metallurgy, and it is therefore certain that this volume, of which the price is very moderate in the present circumstances, will receive the most cordial welcome from the thousands of technicians for whom it has been prepared, and we must hope that the committee which directs this important publication will rapidly publish the abstracts during the last few years, so as to constitute Volume 5 of the "Tables Annuelles de Constantes," years 1917 to 1922.

The King has approved of the award by the President and Council of the Royal Society of a Royal Medal to Prof. C. J. Martin, F.R.S., for his researches on "Animal Metabolism." The President and Council have also awarded the Copley Medal to Prof. H. Lamb, F.R.S., for his researches in mathematical physics, the Davy Medal to Prof. H. B. Baker, F.R.S., for his researches on "The Complete Drying of Gases and Liquids," and the Hughes Medal to Prof. R. A. Mellikan for his determination of the electronic charge and of other physical constants.

PARLIAMENTARY NEWS

Anglo-Persian Oil Company (Government Holding)

Mr. Chamberlain, replying to Lieut.-Col. Hodge, said that a proposal for the acquisition of the Government holding in the Anglo-Persian Oil Company had been under consideration for some time. No decision had yet been reached, but no step would be contemplated by the Government which would have the effect of jeopardising the supply of oil fuel for the Navy and mercantile marine.—*Nov.* 15.

Dried Milk

In answer to Mr. Hurd, Sir W. Joynson-Hicks said that the new Regulations as to dried milk made provision for a minimum fat content and for suitable labelling, including the use of the words " Unfit for Babies " in the case of skimmed milk. It was necessary to allow a period of several months before bringing the Regulations into force, so as to enable manufacturers to comply with the requirements as to the composition of the product, to print new labels, and to put the milk into circulation in retail shops. The question of making Regulations affecting other milk products was receiving consideration.—*Nov.* 15.

Food Preservatives

Sir W. Joynson-Hicks, answering Mr. Barnes, said that he had received a number of resolutions from local authorities, expressing the opinion that the use of chemical colouring matter and preservatives in food constituted a menace to the community, and that the matter was being investigated by a Departmental Committee. *Nov.* 15.

DRIED MILK REGULATIONS

The Ministry of Health has issued an order (No. 1323 of 1923, price 2d.) entitled the Public Health (Dried Milk) Regulations, 1923, to come into force on May 1, 1924. The Regulations apply to dried milk to which no other substance has been added and to the dried milk contained in any powder or solid of which not less than 70 per cent. consists of dried milk, but not to sales of dried milk contained in a receptacle whose gross weight exceeds 10 lb., or to dried milk sold by weight but taken out of a receptacle that is properly labelled. It is forbidden to sell or expose for sale any dried milk unless the container is properly labelled or the milk contains, if dried full-cream milk, not less than 26 per cent. milk fat; if dried three-quarter-cream milk, not less than 20 per cent.; if dried half-cream milk, not less than 14 per cent.; and if dried quarter-cream milk, not less than 8 per cent. Methods of labelling dried milk, so as to protect the consumer, are set out in the schedule to the Regulations. A circular accompanying the Regulations compares them with those previously issued for condensed milk.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Nov.* 8 *and* 15)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Artificial silk yarns	554
Australia	Silk, artificial silk	525, 526
Brazil	Tinplate, chemicals	556
British India	Copper sulphate, steel	*
Chile	Newsprint paper	557
Czecho-slovakia	Metals and alloys	533
Egypt	Linotype metal (tender)	11807/F.E./E.C.
Germany	Steel, leather and kips	535, 537
Netherlands	Leather	538
,,	Medical supplies (tender)	20953/F.W./C.C./2
New Zealand	Cast iron pipes	528
Norway	Cast iron pipes	542
Poland	Steel goods, chemicals	543
Spain	Hollow ware, iron and steel	545
,,	Drugs, chemicals	546
Switzerland	Pharmaceutical products.	547
United States	Firebricks, leather goods	550
,, ,,	Glassware, leather goods	552
,, ,,	Fancy leathers	20990/F.W./M.C./(2)
Yugoslavia	Hides, skins	543

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1.

TARIFF CUSTOMS EXCISE

New Zealand.—The current issue contains copy of the new Amendment Act, showing special rates of duty on certain goods.

Rumania.—Prohibition has been placed on the export of oils, paper, zinc, brass, metal, gold and silver, skins, ores, copper, platinum, copper sulphate, pig iron, pharmaceutical products, petroleum, and caustic soda.

South Africa.—The current issue gives a list of patent and proprietary medicines which are exempted from the stamping requirements.

Spain.—The importation of foreign pharmaceutical specialities is permitted.

Uruguay.—Import duties and additional *patente* charges have been levied on hardware, and pharmaceutical specialities.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No material changes have taken place in the heavy chemical market, but a more hopeful tone has developed, with an improved demand from the textile trade.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 9d.—4s. 3d. per carboy d/d. North of England. £6—£7 per ton in London.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal.

Acetate of Lime—	
Brown	£12—£13 per ton d/d. Demand steady.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 10s. per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. per gall. 60% O.P.
Solvent	6s.—6s. 3d. per gall. 40% O.P.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s.—1s. 1d. per lb. Weaker with limited demand.
Crude 60's	3s.—3s. 3d. per gall. Limited business for spot delivery. No market for forward delivery.
Acid Cresylic—97/99	2s.—2s. 2d. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d.—10d. per gall. Quiet.
Unstrained	9d.—9½d. per gall. Quiet.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.

Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Good business being done.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d. per gall. Fair demand for export.
Solvent 90/190	1s. 2d.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 10s. per ton.
Flaked	£19 10s. per ton.
Pitch, medium soft	125s.—135s. per ton, according to district and time of delivery. Little business.
Pyridine—90/140	21s.—23s. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 9d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 9d. per lb. 100% basis d/d
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	1s. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. per lb. d/d.
m-Toluylene Diamine	5s. 2d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The shortage of spot supplies of a number of products continues and prices are in consequence considerably higher for a few of the pharmaceutical chemicals which are in regular demand.

Acid, Acetic 80 % B. P.	£48 per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 9d. per lb. In strong demand. Most makers fully sold ahead.
Acid, Benzoic	B.P. quality unobtainable.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 4½d. per lb., less 5%, for ton lots. Firmer. Demand improving.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d. per lb. Very firm market.
Acid, Tannic	3s. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Rather more inquiry, but low prices being accepted for foreign acid.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 2s. 9d. per lb. Small stocks.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. per lb. for English make.
Atropine Sulphate	12s. 6d. per oz. for English make. Demand very poor.
Barbitone	17s. 6d. per lb.
Benzonaphthol	5s. per lb. Quiet.
Bismuth Salts	A steady market. Prices according to quantity :
Carbonate	12s. 9d.—14s. 9d. per lb.
Citrate	11s. 4d.—13s. 4d. ,,
Salicylate	10s. 2d.—12s. 2d. ,,
Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	7½d. per lb. Remain very firm. Continental prices advancing.
Ammonium	8½d. ,, ,,
Sodium	8d. ,, ,,
Calcium Lactate	2s. 9d. per lb. for best English make.
Chloral Hydrate	4s. 3d. per lb. Position very firm.
Chloroform	2s. per lb. for cwt. lots. More active.

Creosote Carbonate	7s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 13s. 6d. per lb. Still advancing.
Hexamine	4s. 6d. per lb. Very firm market.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	1s. 11d.—2s. 3d. per lb., according to quality.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£72 10s. per ton, less 2½%. Reduced by £5 per ton.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	2s. 10d. per lb. for carboys. Brisk market. Higher values expected.
Methyl Sulphonal	Has further advanced to 23s. per lb. Small supplies.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 6d. per lb.
Phenacetin	7s. 6d. per lb. Steady market.
Phenazone	8s. 9d. per lb. Again dearer.
Phenolphthalein	7s. 9d. per lb. Very firm.
Potass. Bitartrate— 99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Price advanced 1s. per lb. Demand continues.
Potass. Permanganate	10d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Salol	4s. per lb.
Sod. Benzoate	Practically unobtainable.
Sod. Citrate, B.P.C., 1923	1s. 9d. per lb. for cwt. lots.
Sod. Hyposulphite—	
Photographic	£15—£17 per ton, according to quantity, d/d. consignee's station.
Sod. Nitroprusside	16s. per lb. Less for quantity
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 10d. per lb., and Crystal at 2s. 11d. per lb. Firm and very active.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	3s. 6d. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s. 9d. to 13s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	20s. ,, ,,
Linalyl Acetate	20s. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Ketone	47s. 6d. ,, ,,
Musk Xylol	13s. 6d ,, ,,

TRADE NOTES

Trade Information

X-ray Spectrography is a province of science no longer belonging solely to the physicist, as it is utilised by chemists to study the molecular structure of crystals and powders, thus obtaining data from which the molecular weight can be calculated and hence the composition inferred. Materials used as anti-cathodes can also be analysed by means of the spectrum emitted, a method analogous to spectrum analysis with visible and ultraviolet radiations. In addition the method provides a valuable tool for the metallographer, the crystallographer and the radiologist. A pamphlet received from Adam Hilger, Ltd., 75a, Camden Road, London, N.W. 1, describes Dr. Müller's X-ray spectrograph, which is extremely compact, of simple design and sufficiently inexpensive for use by advanced students. The instrument can be used for work on crystals or powder by the three standard methods of Bragg, Debye, and Hull, and is supplied at the price of £44, the case costing £3 extra. An interesting feature of the pamphlet is the useful introduction written for those to whom the subject is comparatively new.

Plant.—We have received from Messrs. Manlove, Alliott and Co., Ltd., a series of illustrated folders describing various products of this Nottingham firm. Sheet No. 5571 illustrates various types of drying machines manufactured for the chemical and allied trades, such as vacuum, rotary, film, centrifugal and other driers. The selection of the most suitable type of dryer depends on the available source of heat, the nature of the material to be dried, its initial moisture content and the amount of moisture to be removed, questions on which the maker's experience is at the service of clients, who are supplied with a list of questions to answer. Further information can be obtained from the makers at Bloomsgrove Works, Nottingham. Sheets No. 5572 and 5573 relate respectively to machinery for the manufacture of compound feeding cubes for cattle and to washing machines, hydro-extractors, etc., used in the laundry industry.

Electric Furnaces are rapidly becoming commonplaces in industry, especially in the electrochemical and electrometallurgical industries. There is room for much improvement, however, especially in the direction of increasing the efficiency of electrodes, a subject which is treated in an interesting little book, "The Carbon Electrode," published by the National Carbon Co., Inc., of 30 East 42nd Street, New York. After a concise but well-documented review of the history of the electric furnace and the electrode, the manufacture, characteristics, handling and uses of carbon electrodes are described. Notes on methods of joining electrodes and securing minimum consumption are given, and a list of "don'ts" is followed by short chapters on specifications for electrodes, joint compound, the importance of furnace records, carbon resisters, carburite (a material used for bringing the carbon content of steel up to a desired point), carbon blocks, etc. The book closes with diagrams of wiring for electric furnaces, and a series of formulæ and tables. There is a useful index.

Water Softening is every day acquiring still greater importance as the result of the increasing use of higher pressures in boilers and the consequent necessity, if full efficiency is to be attained, of utilising feed water of the right quality. Attention may be drawn to three booklets issued by Sofnol, Ltd., Westcombe Hill, Greenwich, S.E. 10, and devoted to the chemistry of water softening, water testing and calcium hydrate. In the first booklet the chief facts relating to the softening of water are set out and the requisites of the necessary chemicals are given. As a rule, the mechanical part of softening is well cared for, but the chemical treatment is neglected, so Sofnol, Ltd., undertake to supply the necessary materials to soften any kind of water mixed in the right proportions and complying with a definite specification. The second booklet deals with apparatus and chemicals for testing waters, and in this connexion, again, the companies' laboratories and staff are placed at the disposal of clients who desire advice on the treatment of their water supplies. In the third booklet the advantages of using calcium hydrate or calcium-sodium hydrate (soda lime) for the softening of waters are given. The three booklets convey much interesting information, and should be read by those who are concerned with the problems under review.

Cost of Producing Sodium Nitrite in Norway

In an investigation made by the United States Tariff Commission, the cost of production of nitrite by the Norsk-Hydro Co., of Norway, was estimated at 2·183 c. per lb., at current exchange, or 3·275 c. per lb. at par exchange. The cost of transportation of sodium nitrite from Norway to the United States is slightly above ½ c. per lb., and if the estimated cost of production be accurate, the Norwegian producers are placing it in New York at a cost of less than 3 c. per lb. at current exchange values, including production costs, packing, freight and insurance. In March, April and May, the imports amounted to 1,073,000 lb., the average invoice value being 4·84 c. per lb., c.i.f., New York. Deducting transport charges, the average price received at the factory in Norway was 4·34 c. per lb. The spread between the landed cost and the selling price of at least 7½ c. per lb. must include 3 c. per lb. duty. The profit, according to these estimates, would be more than 100 per cent. The above-mentioned company has an annual capacity for sodium nitrite of about 24,000,000 lb. It uses the arc process, and also manufactures sodium nitrate, the daily capacity being 441 short tons of calcium nitrate, 44 t. of sodium nitrate, and 33 t. of sodium nitrate. In the United States calcium and sodium nitrate are not produced in connexion with sodium nitrite.—(*Chem. and Met. Eng., Sept.* 24, 1923).

Chilean Output of Copper

In 1922 the production of copper in Chile was 109,420 tons of copper in bars ; 116,645 t. of ore ; and 110 t. of manganate of copper. At the end of November 97,640 t. of bars, 104,025 t. of ore and 101 t. of manganate had been sold. Chile has thus regained her rank as second producer of copper in the world.—(*Ch. Comm. J., Sept.* 28, 1923.)

Sulphur Production in Australia

The Commonwealth Government has decided to pay a bounty of £2 5s. a ton on all sulphur produced in Australia from local pyrites and other sulphide ores or concentrates. When sulphuric acid is produced from Australian pyrites and other sulphide ores or concentrates, the bounty will be paid on as much sulphur as would be necessary to produce it. The Commonwealth Parliament have passed a bill providing for the appropriation of £100,000 each year for the payment of the bounty, and another bill allowing the free importation of sulphur as long as the bounty is payable. Several large companies have agreed to instal plants for the purpose, which will be sufficient to provide for all Australian requirements.—(*Comm. Int. J., Canada, Oct.* 20, 1923.)

Wages in Russia, 1922.

The following figures show the average wages in Russian industry before the war and in 1922, in pre-war roubles :—

		1922				
Industry	1913.	Jan.	Apr.	July	Oct.	Dec.
Metal	33·4	8·60	10·22	15·83	19·40	22·73
Textile	21·5	8·36	6·17	9·50	10·66	15·73
Chemical	23·0	8·03	9·37	13·88	16·31	19·84
Average	25·3	8·82	7·99	12·97	16·59	19·57

The following table gives the actual monthly wages in 1922 in millions of Soviet roubles of the old issue :—

Industry	Jan.	Apr.	July	Oct.	Dec.	Increase Dec. Jan.
Metal	3·38	34·62	89·26	177·72	409·29	121
Textile	3·29	20·90	53·55	97·69	283·06	86
Chemical	3·16	31·76	78·28	149·43	357·39	113
Average	3·47	27·09	73·14	141·99	354·22	102

Industrial Research.

At the recent annual meeting of the "Fachausschuss des Vereins deutscher Eisenhüttenleute," Prof. P. Göhren, speaking on industrial research, referred to the value of the close relations existing between the industry and universities and research institutes, and mentioned the method of statistical investigation devised by Dr. K. Daeves, by means of which a large number of isolated observations can by simple methods be brought at little cost into useful correlation. The speaker gave examples from his own plant experience of materials, processes and labour.

New Sugar-Mill for Queensland

It is announced that the Queensland Government is about to erect a State sugar-mill at the cost of £389,480 at Tulley River, North Queensland. The mill, which will take two years to erect, will have a crushing capacity of 150,000 tons of cane per season, and will be the largest in the Commonwealth.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, NOVEMBER 30, 1923 No. 48

EDITORIAL

THE world of chemistry is represented in the present Election by a number of candidates, one of whom, Col. J. W. Weston, has already been returned as the Member for Westmorland. Mr. C. S. Garland and Mr. E. Brotherton Ratcliffe are opposing each other in South Islington. Mr. Miller-Jones is fighting the Limehouse Division. Dr. G. C. Clayton, one of the small chemical band in the last Parliament, is again standing for Widnes. Sir Alfred Mond and his colleague, Sir John Brunner, are standing for West Swansea and Southport respectively, while Mr. Henry Mond, Sir Alfred Mond's son, is a candidate for the Isle of Ely. Sir William Alexander and Mr. H. J. Tennant, who comes of a chemical family, though he would hardly call himself a chemist, are opposing each other in Central Glasgow. There are several others who have a connexion with the chemical industry, of whom we may mention Mr. R. S. Brown, of the Brimsdown Lead Company, a candidate for Edmonton, and Mr. R. J. Neville, the Chairman of the Brentford Gas Company, now standing for South Leeds, a seat he has already contested five times. No doubt there are others whose chemical interests have escaped our notice. It is of considerable importance to chemistry and the chemical industry that these should be adequately represented in Parliament, and we hope that this representation will grow until so fundamental and essential a constituent becomes of numerical importance. Chemistry plays a far more dominating part in industry than it did twenty years ago, and our statesmen will easily make a number of blunders in chemical matters, unless there are on the spot a few watchful men who can lend a hand.

* * *

A friendly critic has commented on a recent editorial note which contained some idle speculations on the inheritance of colour in plants and the possibility of some vital principles independent of ordinary chemical molecules. Very likely such notions are too crude to justify the use of our space and our reader's time, both of which are very precious, but there is a certain fascination—perhaps unduly developed in immature minds—in attempting to solve problems, the essential data of which are missing. Those who in the old days devoted much time to squaring the circle were not deterred by any doubts conveyed to them by mere academic men. "Prove to me that the thing is impossible," said one such man, "and I will at once attempt it." And it will probably be found that metaphysical theories on the origin and meaning of life, its persistence and the whole question of spiritual and psychical phenomena, will be promulgated without any regard to the evidence in support of them and the impossibility in our present conditions of obtaining any. Macaulay said: "Such speculations, on the contrary, are in a peculiar manner the delight of intelligent children and of half civilised men. The number of boys is not small who, at fourteen, have thought enough on these questions to be fully entitled to the praise which Voltaire gives to Zadig. 'Il en savait ce qu'on en a su dans tous les ages; c'est-à-dire fort peu de chose.'"

* * *

The announcement made some time ago that experiments were being made on the use of mercury vapour to furnish motive power for turbines was received with incredulity. Novelty is the dearest to us of all things, said Ovid, but his saying would seem to apply more to popular catchwords or amusements than to scientific research, which needs the support of no little and weighty fact before its results are accepted. In this case, the facts, or some of them, should soon be placed before us, as an experimental mercury-vapour turbine has actually been built and a second one put in operation in the United States, so it is understood. Yet on purely theoretical grounds steam, as was recently shown by Mr. W. J. Kearton, speaking before the Institution of Mechanical Engineers, is by no means ideal as a source of power for turbines, for an ideal vapour should possess a high boiling-point, a high pressure at the temperature of circulating water, and a high ratio between its latent heat and specific heat. Such properties are possessed by no single fluid, and this lead Du Tremblay, in 1850, to use two fluids, and resulted in the present attempt to employ mercury vapour as the fluid of high boiling-point, the condensation of the vapour, after passing through the turbine, being utilised to generate steam, which then is superheated and passed through a turbine. Although the overall efficiency of a turbine constructed on this principle would be less than that of the Diesel engine, it is still superior to that of the steam turbine; and, as the mercury system can be constructed in high powers, its use for the generation of electric power on a large scale becomes a suggestive possibility. Already, so it appears, the obvious danger of leakages of the extremely poisonous vapour has been overcome by the use of special jointing, and there ought thus to be no fear for the safety of workers should the mercury-vapour turbine be utilised as a commercial prime mover. Mercury is, of course, extremely expensive, but as there will hardly be any loss, and as it is stated that the quantity required is not excessive, the difficulty of prime cost should not present too formidable an obstacle. Truly, should the system prove capable of industrial exploitation, mercury will once more have shown itself to deserve its reputation.

* * *

It is, indeed, refreshing to find some attempt to leave the rut of the usual and to forget the obvious. The obsession of the known and proved has far too often obscured the value of the unknown, unproved, though possible. Science has provided industry with very many tools to try, but how few of them have received trial, and when worth has been demonstrated, how slowly have they been received in practice! Solvents, analytical methods, apparatus and many other materials or processes have their tale of neglect to tell. The history of chemistry is full of instances. But no student of chemistry need despair while there is so much work to be done, so many gaps to be filled, so many chasms to be bridged. Anyone who has hunted through the literature for information on any subject can at once recall the too frequent omissions, the strange neglect of details, the unsatisfactory nature of the data. It has been said, a dwarf standing on the shoulders of a giant may see farther than a giant himself. There were many giants of old in chemistry, but who would not be such a dwarf?

OUR WATER SUPPLIES *

By EDWIN THOMPSON

There are not many people in a town who give much thought to their water supply. They know that they can turn on a tap and get water that they can drink or bathe in or use for any other purpose, and there the matter ends for them. Suppose they could see microbes in it or if it was of bad colour or had a bad taste or smell, then they would feel they had just cause for indignation. Every city desires a supply of pure and wholesome water, that is to say, water which is delivered to the consumer in such a condition that it cannot cause typhoid, cholera, diarrhœa or other waterborne disease. It must also be free from chemical poisons and have no injurious action on metals. It should be bright, clear and sparkling, free from suspended matter, acceptable to the palate, reasonably soft, and the salts in solution should not be present in excessive amount.

Sources of Water Supply

There are many sources of water supply, such as rain-water, which is collected as it falls and runs into tanks. Gibraltar, for example relies on rain-water for its supply, there being water-collecting slopes of corrugated iron covered with concrete, draining into a channel that runs through a tunnel in the rock and out near the city. Surface wells only a few feet deep are used when there is gravel or other porous soil resting on hard rock or clay, and deep wells, where there is a great depth of porous rock. Use is also made of artesian wells, springs, rivers flowing through nearly level country and mountain rivers flowing through valleys which can be dammed so as to form reservoirs, which will give a steady supply of water all the year round.

The amount of water to be obtained from wells is always somewhat problematical, whereas it is possible to estimate correctly a river supply or the yield of a gathering ground. Up to comparatively recent times wells were preferred not only because of the apparent abundant supply, but also because the water so often had a constant temperature and was naturally pure. At one time France considered that the purity of springs was unquestionable, but frequent epidemics of typhoid in Paris caused a change of opinions and methods. Germany, however, had preferred filtered surface water, but some theorists started a campaign against it and the opposite direction to France was followed with disastrous results.

Purification of Water

The three chief ways of purifying water are filtration, storage and sterilisation, which can be used either separately or in conjunction. The slow sand filtration is the one most commonly used and it has really never been surpassed. There have been many inventors of patent filters and they all seem to say that sand filtration is the worst system, but as it is practically the only one in general use and is not patentable, the would-be inventors have not as yet made much headway. There are many styles of rapid mechanical filters, but these do not give first-class bacteriological results. At Chester, however, rapid filters have proved most useful in dealing with flood water and so prolonging the life of the secondary filter beds. They are also in use at Birkenhead and are very largely used in America. With nearly all rapid filters a coagulant, usually aluminium sulphate, is used in order to produce an artificial skin and to render the filtrate as satisfactory, both chemically and bacteriologically, as it would be if the water had been filtered slowly through the ordinary sand filters. The output of a rapid filter is about 150 to 200 gallons per sq. foot per hour. When water is coloured, *e.g.*, the brownish tinge from a moorland peaty soil, there is nothing so good as a rapid filter for removing the colour.

---

* Address read before the Liverpool Section on November 16.

Liverpool obtains most of its water from Lake Vyrnwy, all the water passing through slow sand filter beds at Oswestry. Not only is there no need to sterilise the water, but the supply is abundant, exceedingly soft and remarkably pure.

In countries where the winter temperature is likely to fall much below freezing-point it is desirable that the filter beds should be covered. This adds very greatly to the cost of the filters, but the darkness tends to reduce the growth of algæ and so the scraping of the surface of the filter beds is not required so frequently.

In 1892 the city of Hamburg had a terrible epidemic of cholera, due to the use of unfiltered water from the River Elbe. Work on filter beds, in course of construction, was immediately pressed forward, working day and night, and since the introduction of filtered water the death rate has been lower than ever before in the history of the city.

Storage

The storage of water is nature's own way of purifying it up to a very high standard. A single day's storage in a reservoir has been found to reduce the number of microbes in river water by 40 per cent. Sir A. Houston, the water examiner to the Metropolitan Water Board, gives some striking instances of the effects of storage on certain microbes. For example, he put cholera microbes into river water to the number of 13 million per c.c. After one week's storage they were reduced to 20 per c.c. and in three weeks they were all dead. In a similar experiment with artificially cultured typhoid bacilli he put 8 million per c.c., and after one week the number was 3000 per c.c., after two weeks 30 per c.c., after three weeks 4 per c.c., and at the end of four weeks they had all disappeared. He found that uncultivated bacilli perish much more rapidly than the cultivated bacilli and it is of course only the uncultivated bacilli that could pollute our water supplies.

Sterilisation

The best method of sterilisation is by chlorination. Sir A. Houston, one of the pioneers of this process, showed that the addition of 15 lb. of chloride of lime to 1,000,000 gallons of Thames water destroyed the microbes derived from previous sewage contamination far more effectively than by passing the water through a reservoir containing 88 days' supply. It is usual now, however, when the water has to be sterilised to use chlorine gas. The advantages are that it can be used in a state approaching absolute purity, it can be stored under pressure in steel cylinders, and it is not subject to atmospheric influences. One to two parts in 5 million has been found sufficient to sterilise completely the water in an hour or so. When chlorinating water, taste is one of the main things to be avoided. The chlorinous taste usually occurs through over-chlorinating, and the iodoform taste through not chlorinating sufficiently; the latter can be removed by potassium permanganate in doses of 2 to 8 lb. per million gallons. The most certain way to overcome the taste trouble is to super-chlorinate and then to dechlorinate with sulphurous acid; this is, however, an expensive method. The wonderful and almost astounding results of water chlorination during the war and the consequent immunity from disease of the troops, both in France and in the East, brought this method of sterilisation rapidly to the fore.

Municipal Waterworks

Glasgow was the first great city in Great Britain to obtain its water from a distant upland source. In 1855 the Loch Katrine waterworks was commenced and the surface of the water was raised 4 ft. by means of a dam; the levels of Loch Vennachar and Loch Drunkie were also raised for use as compensation reservoirs. This gave a storage capacity of nearly 6000 million gallons. There is a service reservoir eight miles from Glasgow, and the distance from Loch Katrine to the service reservoir is 25¾ miles.

Manchester raised the level of the water in Thirlmere 50 ft. and it is 96 miles from its source of supply. Manchester also has five reservoirs in Longdendale about 16 miles away, and these are still used to supplement the Thirlmere supply. This water, like Thirlmere, is very soft and therefore suitable for dyeing and bleaching. It is said that in Manchester the change from hard to soft water effected a saving in soap and soda of between £80,000 to £100,000 a year.

Birmingham obtains its water from 73 miles away in the Elan valley, where three dams were built in 1904 to form three reservoirs. There are also plans for three more reservoirs in the Claerwen valley, but as yet they have not been required.

The supply of water for London comes from the Rivers Thames and Lea and from a great number of wells. The whole London basin is chalk; London itself is on clay, but underneath the clay is chalk generally 200 to 300 ft. deep, although near Regent Street it comes to within 60 ft. of the road level and at East Greenwich it comes to the surface. Roughly 1000 artesian wells draw water from this huge underground reservoir, but they are mostly privately owned. So much water is being drawn from these wells and springs that the rain cannot flow through the sand and chalk fast enough to keep up the pressure and cause the water to flow to the surface, so it has to be raised by high pressure pumps from a depth amounting sometimes to more than 200 ft. During the last 60 years the water in some of the London wells has fallen more than 100 ft. It has been falling at an average rate of 2 ft. a year for many years. Of the total water supply of London, the Thames affords about 60 per cent., the Lea 20 per cent., and the springs and wells 20 per cent. There are now 31 storage reservoirs on the Thames and 17 on the Lea.

The Metropolitan Water Board has to cater for a water supply to nearly 7 million persons, and considering that 80 per cent. of the water is drawn from the Rivers Thames and Lea, which are undeniably polluted, the immunity of London from epidemic waterborne diseases is very remarkable: the death rate from typhoid fever in London in 1922 was at the phenomenally low rate of 1 per 100,000.

In round figures the average daily water supply of London is 250 million gallons and 274 engines of 43,417 h.p. are required to collect and distribute it through 6577 miles of pipes. Possibly people would not waste water so much if it were realised that all the water had to be pumped once and a large proportion of it twice and that the cost of fuel for this purpose is tremendous. Taking the Thames river supply alone at 150 million gallons per day it would be sufficient at 35 gallons per head per day to supply the whole of Liverpool, Manchester, Glasgow, Birmingham, Sheffield, and Bradford. This gives some idea of the huge scale of the Metropolitan Water Board's undertaking.

When the Thames is in high flood the chlorination treatment is discontinued temporarily and Staines Reservoir water is used instead, but, as this water has been stored for six to nine months it is in a very high state of purity. With the New River, however, the results are so good during three-quarters of the year that chlorination is only practised during the flood months.

WATER SOFTENING

One advantage of storage is that it has quite an appreciable softening effect upon water. Water softening is, of course, almost entirely carried out by private enterprise for special purposes as the greater part of any city water supply is used for flushing and other purposes where it does not matter whether the water is hard or soft.

CONSUMPTION OF WATER

It is interesting to note the difference in consumption of water per head in this country and in America. Here we use from 30 to 40 gallons per head per day, whereas in America anything from 150 to 200 gallons per head per day is required. Few water undertakings in this country have a large margin over their requirements, and I anticipate that in 10 or 15 years' time the consumption per head in this country will have materially increased, and that many water engineers will be faced with a difficult problem.

IMPURITIES IN WATER

Since November, 1920, the suspended solids in Thames river water have been determined gravimetrically. The weight in lbs. of suspended matter per million gallons was 27 for the week ending September 3, 1922, and 629 for the week ending January 7, 1923, this showing, of course, the great difference at the end of the summer and middle of winter. This difficulty of suspended solids adds very greatly to the problems of filtration.

People do not often realise what a trial gulls may be to the water engineer. As the gulls fly up the Thames Estuary they regard the West Middlesex Works as a haven of rest and there are also plenty of fish there. As each gramme of their droppings may contain a million typical *B. coli* they are not particularly welcome. Even as far inland as Lake Vyrnwy the gulls are frequently a great trial.

The storage of water is not without its difficulties. It may kill certain microbes and bacilli, but on the other hand it may encourage the growth of plant and animal life. Sponges, polyzoa and mollusca in endless variety may get into the storage reservoirs and block up the mains to an alarming extent. At Newton Abbot a polyzoan (*Plumatella*) got into the mains and within a year was found in every part of the district of supply. A similar thing happened in Torquay, and in another case an important metered supply was blocked up on four successive days and an electric lighting station was forced to close down at the time of maximum load, because the meter was blocked. The trouble, however, was overcome by the installation of mechanical filters near the reservoirs.

Trouble arose in the Cardiff waterworks owing to the presence of sponges and in 1911 the growth was so extensive as to cause great anxiety, not only by the reduced flow in the pipes, but also on account of the unpleasant odour. The chief trouble was in a 36 in. main, which was encrusted with a luxuriant growth of sponges, some eight inches long. Local scouring and treatment with strong brine proved successful.

Fresh-water mussels may suddenly appear and in the spring of 1912 the diameter of a 36 in. unfiltered water main at Hampton-on-Thames was reduced to 9 in. It is said that 90 tons of shells were removed.

Minute crustaceans, such as *Cladocera* and *Copepoda* and others may appear in overwhelming quantities. On one occasion in Antwerp the water flea, one of the *Cladocera*, appeared in such swarms that they continually clogged the screens through which the water passed on to the filters. During several weeks six men were employed day and night changing the screens. Ten tons of these organisms were removed. These are only a few instances, but there are scores of other animals that depress the soul of the water engineer.

Algæ are of considerable importance in waterworks, sometimes beneficial, but sometimes the reverse. They purify the water by means of the oxygen they liberate and also are most useful as a purifying film in sand filters. On the other hand they may taint the water by their decomposition and clog the filters by their remains and sometimes cause disagreeable tastes and odours. Diatoms are found in large numbers and the skin or film which forms on the surface of sand filters is to a large extent composed of diatoms, which, on account of their gelatinous coating, stick to the sand grains and gradually fill up the interstices, thereby forming an effective mechanical filter. There are also many floating plankton forms of life that cause great trouble.

The plant life just referred to can only live and thrive in uncovered reservoirs where there is light, but there are bacteria, such as *Crenothrix*, which infest reservoirs and pipes, especially where iron and organic matter is present in solution. It flourishes both in the light and the dark and will suddenly make an unexpected appearance, becoming a great nuisance. The water becomes discoloured by the iron, putrid owing to the decaying protoplasm and the pipes become choked with gelatinous and hardened deposits. The remedy is to aerate the water in order to oxidise the ferrous salts with the insoluble ferric salts, which can be removed by sand filtration. There have been several serious outbreaks of *Crenothrix*. It suddenly appeared at Cheltenham in 1896, and Berlin and Rotterdam have both had to face great difficulties from this cause.

The Liverpool Water Supply

The Lake Vyrnwy undertaking was completed in 1893, the watershed covering 123,150 acres, and the water travels 18 miles to Oswestry, where it passes through sand filters and then travels another 60 miles to Liverpool. There are twelve filter beds at Oswestry with a total area at the top of the sand of 9¾ acres. After about five weeks' use the surface of the filter gets so clogged up that it has to be cleaned by scraping away the surface. After this has been done a number of times the filter has to be re-sanded. The scrapings are taken to a washing machine and the clean sand can be used again. The pipes from Oswestry to Prescot have never given serious trouble, which shows the efficiency of the sand filters.

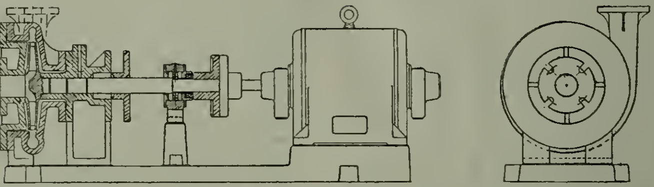
The Liverpool Corporation owns the gathering ground surrounding Lake Vyrnwy and very great care is taken in order that the water shall not be polluted in any way. No houses, of course, are allowed near the Lake unless they drain off the watershed below the dam. It was undesirable to have so much land unproductive if it could be used for some purpose that would not damage the purity of the water, so an afforestation scheme was started and is being extensively carried out with Government help, 1290 acres having been planted. The species of trees which have given the best results are Douglas fir, common spruce, Sitka spruce, European and Japanese larch, whilst other varieties planted include Corsican pine, silver fir, Weymouth pine and beech. The trees are grown from seedlings and several plantations nearly 20 years old have been cut down and replanted. The wood is sold mostly for pit props. There is, however, a large quantity of thinnings and waste that has to be got rid of somehow, so a small plant has recently been installed for the manufacture of wood wool and also hurdles. About 250,000 trees are planted each year now and it will not be long before there are 4000 acres under cultivation. It is a much debated point whether the forests help towards increasing the quantity of water or help its purity; at any rate the land cannot be used for any other purpose and it is a pity that in this country there are not far more and larger tracts of land under forestry cultivation.

Rivington gathering ground covers 10,000 acres, and there are eight reservoirs with a total water area of 600 acres, the total storage capacity being 4105 million gallons. The water is filtered through sand filters at Horwich.

Dr. H. E. Cox has resigned the office of Hon. Secretary of the South Wales Section, which he has held since its inception as part of the old Bristol and South Wales Section some six years ago, on account of his removal to London. The Committee has nominated Mr. H. W. Webb, M.Sc., the present Hon. Treasurer, to be Hon. Secretary, and Mr. Webb has consented to take over the duties from December 1 next.

ACID-PROOF CENTRIFUGAL PUMPS

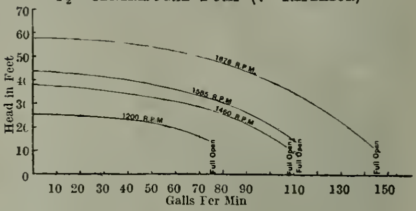
As is well known by bitter experience to technical chemists and chemical engineers, one of the most difficult operations has been the pumping of strongly acid and corrosive liquors. Within recent years, however, remarkable progress has been made with the invention of acid-proof metals, such as, for example, special cast iron with a very high silicon content, and in this connexion one British firm that has done much valuable work is Messrs. Meldrum Bros., Ltd., of Timperley, near Manchester, the well-known makers of destructors and steam jet furnaces, hand or mechanically fired. Messrs. Meldrums commenced the manufacture of acid-proof metals some years before the war, and supplied various simple parts such as pipes and bends. It is not particularly difficult to invent an acid-proof cast iron, but the trouble is that the majority of such metals are almost impossible to work, as they will not pour properly in the foundry, and are intensely hard and brittle, so that castings of any complexity cannot be machined. However, very extensive experience obtained during the war has enabled Messrs. Meldrums to produce a metal that will resist attack by not only sulphuric, nitric, and acetic acid of any strength and temperature, but also even more difficult materials such as chlorine liquors, and which at the same time, by means of special machinery, can be worked satisfactorily in the foundry and the machine shop. As a result there is now available a whole range of centrifugal pumps, particularly difficult work, made entirely of "Meldrum" non-corrosive metal, in which the volute and delivery branch is in one casting, manufactured in standard sizes, the largest being 8 ins. diameter, with a delivery pipe for a height of 120 ft.



2″ M.M. Pump-Motor Driven.
Scale 3″=One Foot.

The set of curves illustrated show the performance of a typical motor-driven pump of this character running at four different speeds, the dimensions of the pump being 2-in. suction pipe, $1\frac{1}{2}$-in. delivery pipe, and 7-in. impellor. As will be seen, the duty of this small pump at 1585 revs. per minute corresponds to about 112 gallons per minute to a height of 44 ft., and in general the performance indicated by these representative curves is quite equal to that of an ordinary centrifugal pump made of cast iron or bronze.

$1\frac{1}{2}$″ Centrifugal Pump (7″ Impellor)



A metal of this character is, of course, useful in all kinds of ways, as for example in the construction of compressed-air mechanical elevators, in which a metal plunger is used operated by the air so that the latter does not come into contact with the acid, and altogether most of the difficult problems connected with the automatic handling of acids can now be regarded as solved.

BRITISH DYESTUFFS CORPORATION, LTD.

It is announced that a scheme of reconstruction of the capital of the Corporation is under consideration by the Board, and an announcement will be made to shareholders as soon as definite proposals can be made. The Corporation has an authorised share capital of £10,000,000 in £1 shares, made up of £4,500,000 preference, £4,500,000 preferred ordinary and £1,000,000 deferred ordinary, of which £4,119,952 preference, £4,090,760 preferred ordinary and £994,190 deferred ordinary shares have been issued. The Government holding consists of 850,001 preference and 850,000 preferred ordinary shares.

FORTHCOMING EVENTS

Dec. 3. Society of Chemical Industry, *London Section*, in the Chemical Society's Rooms, Burlington House, W. 1, at 8 p.m. (1) "The Use and Preservation of Building Stone," by J. A. Howe. (2) "The Chemical Aspect of Building Stone Decay," by Dr. J. J. Fox and T. W. Harrison.

Dec. 5. Society of Public Analysts, The Chemical Society's Rooms, at 8 p.m. (1) "Crystalline Bromides of Linseed Oil," by H. Toms, M.Sc. (2) "The Plea for Standardisation," by M. S. Salamon, B.Sc. (3) Note on the Estimation of Chromium," by H. T. S. Britton, M.Sc. (4) "The Colorimetric Estimation of Lead in Cream of Tartar," by R. L. Andrew. Dinner to be held at 178, Piccadilly, at 6.30 p.m.

Dec. 6. The Chemical Society, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) The additive formation of four membered rings. Part III. A system of nomenclature for heterocyclic four membered rings and the formation and properties of some derivatives of β-methylenediimineoxide. C. K. Ingold. (2) The dependence of polarisation-overvoltage on hydroxyl and hydrogen ion concentration. Part I. Polarisation-overvoltage of an antimony cathode in aqueous alkaline solution. H. J. S. Sand and E. J. Weeks. (3) Stereoisomerism and local anæsthetic action in the β-eucaine group. Resolution of β- and iso-β-eucaine. H. King. (4) β-alizarin. An isomeric form of alizarin. A. Green. (5) The isomerism of the oximes. Part XV. The supposed fourth benzildioxime. O. L. Brady and F. P. Dunn. (6) The alternation in the heats of crystallisation of the normal monobasic fatty acids. W. E. Garner and F. C. Randall.

Dec. 6. Society of Chemical Industry, *Bristol Section*, The University, Woodland Road, Bristol, at 7.30 p.m. "Some Reminiscences of an Alkali Inspector," by R. D. Littlefield.

Dec. 7. Society of Chemical Industry, *South Wales Section*, The Technical College, Cathays Park, Cardiff, at 7.30 p.m. "Coke Ovens," by T. G. Watts, B.Sc.

Dec. 7. University of London, University College, Gower Street, W.C. 1, at 8 p.m. "The Fundamental Concepts of Natural Science," by Prof. G. Dawes Hicks.

Dec. 7. Society of Chemical Industry, *Manchester Section*. Joint Meeting with the Manchester Section of the Institution of Rubber Industry, Midland Hotel, Manchester, at 7.30. "The Analysis of Rubber Vulcanising Accelerators," by T. Callan, M.Sc.; "Methods to be Adopted in Comparing the Activity of Various Accelerators," by G. Martin, B.Sc.

SOCIETY OF CHEMICAL INDUSTRY

HARRISON MEMORIAL PRIZE

In accordance with the trust deed governing the Harrison Memorial Fund, a Selection Committee consisting of the Presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry and the Pharmaceutical Society will meet shortly to consider the first award of the Harrison Prize.

The Prize, which is of the approximate value of £150, is to be awarded to the chemist of either sex being a natural born British subject and not at the time over thirty years of age, who, in the opinion of the Selection Committee, during the previous five years has conducted the most meritorious and promising original investigations in any branch of pure or applied chemistry and published the results of those investigations in a scientific periodical or periodicals.

Provided that in the opinion of the Selection Committee there is a candidate of sufficient distinction to warrant an award of the Prize, the first award is to be made in December, 1923.

The Selection Committee is prepared to receive applications, nominations or information as to candidates eligible for the prize. Any such communication must be received by the President of the Chemical Society, Burlington House, Piccadilly, London, W. 1, not later than Monday, December 10, 1923.

GLASGOW SECTION

The second meeting of the session was held in the Institution of Engineers and Shipbuilders, Elmbank Crescent, on November 23, Mr. W. E. Moodie, in the chair, when a paper on "Artificial Resins" was read by Dr. H. Hepworth.

The subject was introduced by brief reference to the natural resins, and it was pointed out that, despite the advanced state of modern organic chemistry, practically nothing was known of the constitution of these bodies since their amorphous nature made investigation by the usual methods impossible. Dr. Hepworth then touched on the early history of artificial resins, saying that no doubt the first chemist to make such a substance was just the first worker on organic chemistry. The various types of resinous condensation products were briefly described; of special interest were the resins from furfural, now available in large quantities as a product of hydrolysis of corn cobs and from acrolein, a compound closely studied by French workers during the war and employed by them in gas warfare. The application of tetrahydronaphthalene as a solvent for synthetic resins was mentioned.

During the discussion which followed Mr. W. H. Nuttall pointed out that synthetic resins were definitely superior to natural resins in electrical transformer work.

NOTTINGHAM SECTION

Mr. S. F. Burford presided over the meeting held on November 21, and a paper was read by Dr. H. S. Holden and Mr. J. E. T. Gilbert, entitled " Observations of some Micro-organisms growing in Glycerol." In general glycerol has a lethal action on bacteria and this fact is made use of in the sterilisation of calf lymph (for use in vaccination). A 50 per cent. solution of glycerol is commonly used in biological laboratories and examination of a stock solution which had not been used for some time showed a white flocculent precipitate. Microscopical examination of this substance revealed one dominant mould (a species of *Pencillium*) and several kinds of yeast. Investigations of two of the most important of these yeasts showed one which produced smooth circular white colonies in agar, and the other which was pink and had similar characters. The white yeast grew well in all the ordinary laboratory media, but most freely on beerwort agar at 34° C. It did not ferment lactose, but maltose and saccharose were fermented very slowly. Glucose was fermented rapidly with the formation of acid and gas, and glycerol was fermented with the production of traces of alcohol and formic acid. It grew freely in solution from 5 to 20 per cent. concentrations with the formation of acid, and more slowly even in 50 to 75 per cent. solutions. The pink yeast resembled the white one in its tolerance of high concentrations of glycerol, but fermented glucose only of the carbohydrates mentioned. The effect of the yeasts was to produce general cloudiness in the glycerol, and the flocculent deposit was developed as a result of infection by moulds. Probably both the pink yeast and fungus were due to air contamination, though the white yeast might be derived from the glycerol itself. It had not been found possible to identify this white yeast with any known species, although it resembled the *Saccharomyces Hanseni* isolated by Zopf from cotton-seed oil. The growth of both yeasts and mould was inhibited by the addition of two drops of chloroform water (B.P.) to 10 c.c. of the culture solution.

Mr. H. Droop Richmond said that Dr. Holden had mentioned that the lethal action of glycerol in micro-organisms was possibly due to the precipitation of the proteins. Mr. Richmond was not aware that glycerol acted as a protein precipitant, and considered that it produced plasmolysis, especially as the attenuated growth indicated an increase of osmotic pressure within the cell.

In reply, Dr. Holden stated that Mr. Richmond's view of the plasmolytic influence of glycerol was not at variance with his suggestion as to the protein-precipitating action of glycerol. Glycerol in dilute solutions caused the living matter to shrink inwards from the cell wall, the reverse process occurring if the cell was subsequently immersed in water. A state of irreversible plasmolysis resulted from the immersion in higher concentrations of glycerol and was probably accompanied by protein precipitation.

A second paper was read by Mr. Lambourne on " Organic Compounds of Tin," in which he described some properties of methyl-stannonic acid as first prepared by Mayer. The constitution of this substance was represented by the formula $CH_3 \cdot SnOOH$, and he described a new class of acyl derivatives, which were of a decidedly more complex type—probably derived from a condensation of three molecules of the ortho form of the methyl stannonic acid $CH_3Sn(OH)_3$. Two distinct types of such derivatives had been prepared, each containing three tin and three oxygen atoms alternately combined. One type appeared to be a straight chain of such atoms, and the other of cyclic structure $(CH_3SnOOR)_3$. Further work was proceeding which seemed to show that other derivatives existed of even higher polymerised constitution, where six tin and six oxygen atoms were alternately combined as represented by $(CH_3SnO.OR)_6$.

Dr. Prideaux then gave a demonstration of a universal regulator of acidity, with some suggested uses in analysis. After a short explanation of the symbol p_H and of the advantages of this function in quantitative work, it was shown how rapid changes of p_H with added alkali, etc., correspond to good titrations, whilst gradual changes corresponded to good hydrion regulations such as were given by buffer mixtures. The principle of improving the regulation by the introduction of acids having intermediate dissociation constants was illustrated by means of the "B.D.H." Universal buffer mixture and Universal indicator. In examining beer in this way, pure litmus should be added which should give a red, and to another sample bromphenol blue which should give a violet, thus proving that the p_H lay between the normal limits of 3·9 and 4·7. The exact p_H could then be determined with the universal buffer, *e.g.*, methyl red. The accuracy could be improved by placing behind the buffer standard a test tube of beer without indicator, in order to compensate for the natural colour of the beer. Suggestions were also made for testing the p_H of milk, and of vinegar.

Mr. Burford enquired what was the advantage in taking the p_H of ordinary drinking water. Mr. Calam mentioned that the p_H values of vinegar and beer were very similar but the two substances tasted very differently. What was the sensibility of the palate towards liquors of low acidity ? Dr. J. B. Firth said that the buffer mixture invented by Dr. Prideaux was very good, but he would like to see a universal indicator produced which would show greater sensitiveness. At present the universal indicator was limited, as between certain ranges of p_H only slight colour changes resulted.

In reply, Dr. Prideaux said that the determination of the p_H alone in drinking waters would not give much information except in certain special cases, but it was a very useful datum, when taken in conjunction with the other chemical properties of the water. The sensitiveness of the palate to p_H had been found; his impression was that 0·001 N was about the limit, but it varied considerably according to whether the p_H was produced by a strong acid in low concentration or a weak acid in higher concentration. There was great difficulty in devising a universal indicator which should be equally sensitive in all ranges of p_H, since the colour of each changed two-colour indicator tended to mask that of the next. Work was proceeding with the object of improving the indicator.

YORKSHIRE SECTION

The second meeting of the session was held in the Queen's Hotel, Leeds, on November 19, when an address on "The Work of the Chemist in Connexion with the Textile Industries" was delivered by the chairman, Mr. L. L. Lloyd.

In the opening portion Dr. Lloyd dealt with the production of artificial fibres, discussing the Chardonnet, cuprammonium and viscose silks, their oxycellulose content, variation in composition of the thread, dyeing properties and the question of the non-replacement of all the nitrogen in the Chardonnet thread by any reduction method. After touching upon the facing of cotton with artificial silk, Dr. Lloyd described the treatment of cotton. Treatment with soda and the phosphoric esters of cellulose to modify printing was mentioned, and the want of permanent effect was ascribed to the formation of free acid. The Swiss sulphuric acid treatment gave a permanent effect on the other hand, produced a flexible, linen-like fibre which possessed good dyeing properties and good modification was given by formaldehyde.

Far less work has been done with vegetable than with animal fibres. The bisulphite treatment of coarse fibres to produce the more valuable finer ones was successful in the laboratory, but it had not yet been put into practice and the whole question demanded the attention of the chemist. Further, there was ample scope for the chemist in attempting to fix properties such as elasticity in combinations of vegetable and animal fibres. Again, scouring practice efficiency was far ahead of theory owing, in the first place, to the large amount of experimental work with a large number of substances, often somewhat indiscriminately chosen and which resulted ultimately in good efficient methods. For physico-chemical reasons one colloid would be expected to be as good as another, but it was not so, and when a mixture of colloids was used, there was a gain in efficiency. The use of solvents, dichlorethylene and mixtures, and the work of Sugden and McBain were examined. The scouring efficiency was not entirely due to lowering of the surface tension and merely to colloid action, but was due also to chemical action as the fibre was altered into a form more suitable for technical purposes. The action of alkali was cited in support of this conclusion.

The address was highly successful in provoking a good discussion, nearly every member present taking part. The discussion largely concerned wool; methods of increasing the lustre and the causes of uneven dyeing being the chief points.

AMERICAN SECTION

At a recent meeting of the Perkin Medal Committee, Dr. F. M. Becket, of the National Carbide and Carbon Co., Niagara Falls, N.Y., was elected to be the recipient of the medal, which will be awarded at the meeting on January 11. We append a few notes on Dr. Becket's work that have been furnished by the Honorary Secretary of the American Section. Due to his unusually busy life and a modesty which has found satisfaction in successful endeavour rather than public approval, Dr. Becket's work has been published through his many patents rather than in technical papers. Probably his most noteworthy achievement was the discovery and development of the process for reducing ores by silicon. The method has a wide application to many ores of the most valuable metals, and makes possible the economic production of a superior quality of low carbon alloy well adapted to the manufacture of high-grade engineering and tool steels.

Dr. Becket was the first producer of ferro-vanadium on anything approaching a commercial scale, certainly in the United States, and probably in the world; he was one of the first producers, if not the earliest, of molybdenum by direct smelting methods, and by his work on calcium-carbide manufacture, he has done much to make possible the increase from 500 h.p. production units to the present-day furnaces of over 20,000 h.p. During the war he solved important problems in connexion with the production of zirconium, and he has now shown that zirconium is likely to prove one of the most beneficial of the scavenging and alloying elements in steel manufacture.

Although his greatest achievements have been in the electro-metallurgical field he has also accomplished notable work in the electro-chemical and chemical-engineering fields. His connexion with the experimental stages of the Acker Process was certainly partly responsible for its ultimate development to a manufacturing scale. Various methods for the elimination of harmful impurities from ores, particularly in the treatment of tungsten ores, are due to him, and he has also devised valuable methods of analysis for various alloys and the impurities usually found with them. The above is but a brief résumé of Dr. Becket's varied activities and the list of patents issued to him will illustrate better the scope, and particularly the practicability, of his activities. As well as for his technical ability, Dr.Becket, is esteemed for his many charming qualities and for his high ethical standard

MANCHESTER SECTION

The Annual Dinner was held on November 23, and there was a very large number of guests, including the Mayor of Salford (Alderman J. P. McDougall); Prof. H. B. Dixon, C.B.E., F.R.S.; S. J. Pentecost, Esq.; Alderman F. J. West, C.B.E., M.I.Mech.E.; Dr. E. F. Armstrong, F.R.S., President of the Society of Chemical Industry; Dr. H. Levinstein, Chairman of the Manchester Section; Dr. E. Ardern, Vice-Chairman of the Section; Prof. F. L. Pyman, D.Sc., F.R.S.; Mr. J. Huebner, M.Sc.Tech.; Mr. L. Guy Radcliffe, M.Sc.Tech., and others. The proceedings were characterised by a pleasant informal spirit which made them particularly enjoyable.

The Mayor of Salford (Alderman J. P. McDougall) proposed the toast of "The Society of Chemical Industry and the Manchester Section" in a humorous speech, which was responded to by Dr. E. F. Armstrong and Dr. H. Levinstein in a similar manner.

Dr. H. Levinstein then proposed the toast of the "Allied Societies," coupled with the names of Prof. H. B. Dixon, C.B.E., F.R.S., President of the Manchester Literary and Philosophical Society, and Mr. S. J. Pentecost, President of the Society of Dyers and Colourists, and referred to the felicitous relations which had always existed between the three societies. The toast was responded to by both Prof. Dixon and Mr. Pentecost.

Dr. E. Ardern, in proposing the toast of "The Guests," coupled it with the name of Alderman F. J. West, C.B.E., M.I.Mech.E., and said they were all very proud to welcome in their midst, the civic head of the neighbouring royal Borough of Salford. They were also especially pleased to welcome the President of their Society, and also their General Secretary, Dr. Longstaff, who had laboured so earnestly and faithfully in the interests of the Society. They also welcomed Alderman West, who came among them as the representative of the Manchester Corporation and who was one of the busiest industrial men in Manchester as well as Chairman of the Rivers Committee, a body dealing with the disposal and treatment of the waste products of the city. Manchester owed a great debt of gratitude to Alderman West for the highly efficient way in which he had fulfilled his municipal duties. Alderman West, in acknowledging the toast, referred to the ever-increasing closeness of relationship between the present-day chemist and engineer. Both professions realised that it was absolutely necessary for each side to understand the point of view of the other if there was to be adequate coordination of effort and resultant perfection of output.

The third meeting will be held in the Textile Institute, 16, St. Mary's Parsonage, Manchester, on Friday, December 7, at 7 p.m. This meeting has been arranged jointly by the Manchester Sections of the Society of Chemical Industry and the Institution of Rubber Industry. Dr. H. Levinstein will be in the chair, supported by Mr. J. H. Mandleberg, M.A., chairman of the Manchester Section of the Institution of Rubber Industry. The following papers will be read:—

(1) "Methods to be adopted in comparing the activity of various Accelerators," by G. Martin, B.Sc. (Superintendent, Rubber Investigations, Imperial Institute, representing the Institution of Rubber Industry). The simplest and most generally applicable method for the determination of the potency of an accelerator consists in mixing rubber with sulphur, zinc oxide and an accelerator and vulcanising in steam. The effect of the variable factors on the figures obtained for potency is considered in detail.

(2) "The Analysis of Rubber Vulcanising Accelerators," by T. Callan, M.Sc., Ph.D. and N. Strafford, B.Sc. (representing the Manchester Section of the Society of Chemical Industry). The identification and quantitative determination of the chief commercial organic rubber vulcanising accelerators, including phenolic and nitroso compounds, the aryl guanidines thiocarbanilide, the metallic and alkyl ammonium salts of alkyl dithiocarbamic acids and the alkyl thiuram disulphides.

CHEMICAL INDUSTRY CLUB

The fifth annual dinner was held on Monday, November 26, at the Connaught Rooms, Great Queen Street, London. Mr. H. Edwin Coley (chairman of the Executive Committee of the Club) presided, and there were a number of distinguished guests present, including Lord Exmouth, Sir Lionel Phillips, Bart., and Sir Arthur Duckham. The company also included Mr. W. Cullen, Mr. A. G. Craig, Mr. C. J. Goodwin, Mr. F. W. Harbord, Prof. J. W. Hinchley, Sir W. J. Pope (president of the club), Dr. B. Dyer, Mr. C. A. Ellis Richards and Mr. J. Arthur Reavell.

The loyal toasts having been duly honoured, Sir Lionel Phillips, Bart., proposed the toast of "The Profession and Industry of Chemistry." and coupled with the toast the names of Sir Arthur Duckham and Mr. Harbord.

Mr. F. W. Harbord, C.B.E., F.I.C., responding, said there was no profession—not even the engineering profession—which was brought into more intimate relation with all the industries of the country than the chemical industry. Even engineering would have been impossible but for the chemist; without a Bessemer or a Siemens engineering as we know it to-day would have been impossible.

Sir Arthur Duckham, K.C.B., said he was an engineer who had possibly learned how to talk to the chemist, which was an extremely difficult thing to do. He was very glad to have been asked to attend the dinner, because he was very interested in the chemical industry, and was instrumental, more or less, in forming the new Institution of Chemical Engineers, of which he was the first president.

Sir William Pope, K.B.E., M.A., LL.D., F.R.S. (president of the Club), proposed the toast of "The Chemical Industry Club." After expressing his appreciation of the fact that he had been elected president, he said the Club was looked upon as providing a social link between all the great interests of chemistry, the great corporate interests which were represented by the large chemical societies, and all chemists who had the interests of chemistry at heart hoped that, sooner or later, we should be able to convert all those societies into one great homogeneous whole, housed in a palace which, however magnificent, would never be quite appropriate to what chemistry deserved. The membership of the Club included a variety of different types of people—the chemical manufacturer, the business man and the downtrodden professional class, which he had the honour more intimately to represent. The Club had been going on for, roughly, five years, and had become very important; he believed that it was going to become a sort of "key" Club to the whole of the chemical fraternity. But the members of the Club ought to conserve very carefully a recollection of the men who founded it in face of a good deal of opposition, and should be everlastingly grateful to those men. One of the founders was Mr. Coley (the chairman), whom he (Sir William Pope) hoped to see in the chair for a long time to come. He paid a tribute to Mr. Coley and coupled his name with the toast.

The toast was honoured with enthusiasm.

The Chairman, in response, said that a great deal of work had been done on behalf of the Club by others as well as himself, and he paid a personal tribute to Capt. C. J. Goodwin for the great efforts he had made as Treasurer, from which office he had found it necessary to resign, and to Dr. Hodgkinson and Mr. A. C. Craig, the previous chairmen. It had always seemed to him that those connected with the industry, and particularly the profession, were so immersed in knowledge that they had no time to rest, but it was the object of the Club to provide them with a resting place in which they would have an opportunity of relieving their minds from the constant strain to which they were subjected. As to the future, he believed that, on the Club, the chemical industry could build a real organisation which would be an honour to the industry, and a centre for the whole industry and profession. The Club was the one concern connected with the industry and profession which was unbiassed and uninfluenced by any particular person or persons connected with the trade, and it was on that, he believed, that the future Club would be built.

Mr. W. Cullen then proposed "The Guests," to which Prof. J. W. Hinchley replied.

Mr. A. G. Craig proposed the final toast of "The Chairman." Those who had been connected with the Club for seven years knew the amount of work he had done. On behalf of the members of the Club, he presented to Mr. Coley a gold half-hunter watch, as a mark of appreciation for his untiring work as the Club's first Honorary Secretary.

The toast was honoured enthusiastically, and the Chairman briefly replied.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

During the recent Congress held in Paris (*cf. Chem. and Ind.*, pp. 1082 and 1107, 1923) some interesting discussions took place before Group XI (cellulose and plastic materials), under the presidency of Monsieur de Chardonnet, the inventor of the artificial silk which bears his name. Monsieur M. Jaffard described researches on the preparation of cellulose from the wood of *Pinus maritima*, and gave the results obtained on nitrating it. Monsieur H. Gault gave an account of new mono-, di-, and tri-esters of cellulose, and of the higher fatty acids. The mono-esters are usually insoluble in the common solvents, whereas the di-esters are soluble and can be obtained in yields of 80 per cent. The latter are insoluble in alcohol and acetone. Specimens were shown of dilaurate, distearate and dipalmitate of cellulose, as well as films obtained by evaporating solutions made with volatile solvents. These products promise to be useful industrial materials as the films obtained from solutions in benzene or chloroform are translucent, supple, non-inflammable and resistant to water. Mixed celluloses of definite composition were also obtained that showed properties differing according to the acid radicles which they contained. Interesting di-esters were also obtained from starch without previously rendering it soluble. In a paper on the analysis of synthetic camphor, Monsieur Zelger stated that the true camphor was estimated by precipitation in the form of semi-carbazone, the reaction being almost quantitative. The same author also dealt with the dynamometry of plastic materials, and discussed the conclusions that could be drawn from the yield point of a plastic material, and from its breaking point. MM. L. Clément and C. Rivière read communications on the colloidal nature of cellulose and cellulose esters, in which they discussed the colloidal properties of the cellulose molecule in different compounds, paying particular attention to the researches of H. Gault, Maurice Deschiens and P. Guilleminot on certain related points (*Bull. Ser. Techn. de L'Aeronautique Militaire Francaise, No.* 27, 1919), comparing them with those obtained by Mardles (*cf. J.*, March, 1923). MM. Clément and Rivière also read a paper on the present state of the industry of plastic materials and artificial textiles

Before Group X (rubber and resins), the new method of treating latex and the theories of vulcanisation, and of the preservation of rubber, were discussed by MM. Bongrand, Bory and Bernstein. Oil of turpentine and rosin were dealt with by M. D pont, and M. Cunénot advocated dipterocarpus oil as a substitute for turpentine. Other subjects discussed were the new antimony and titanium pigments, the resistance of paint to sea-water, and new varnishes made from synthetic resins.

FARADAY SOCIETY

Summaries of the papers read at the meeting held on November 12 are appended :—(1) Part 1. "The Electrodeposition of Manganese," by Prof. A. J. Allmand, M.C., D.Sc., and A. N. Campbell, B.Sc. The electrodeposition of manganese from aqueous solutions of its sulphate and chloride was studied, and the effects of changes in composition of electrolyte, current density, temperature and type of cell investigated. It was found that pure manganese in coherent form could be prepared in small quantity with a current efficiency of 40–50 per cent. Attempts to prepare larger amounts in coherent form, however, were unsuccessful.

(2) "An Investigation of Smoluchowski's Equation as Applied to the Coagulation of Gold Hydrosol," by L. Anderson, B.Sc., Ph.D. Colorimetric determinations of the rate of coagulation of gold sols by hydrochloric acid, potassium chloride, barium chloride and aluminium chloride were carried out, using the method of Hatschek, and in agreement with previous investigators, a region of rapid coagulation was found in which Smoluchowski's equation holds fairly well. The equation held most satisfactorily with a certain concentration range of barium chloride as coagulant. A slower region of coagulation was found in which the equation is inapplicable. It was concluded that the Smoluchowski equation in its present form was strictly limited to rapid coagulation. Certain of the results obtained could be interpreted as indicating considerable variations in magnitude of the charge on individual primary particles of the sol.

(3) "The Cathodic Behaviour of Alloys. Part 1. Iron-Nickel Alloys," by S. Glasstone, M.Sc., Ph.D. The investigation brought to light a number of new facts concerning the electrode deposition, overvoltage and action of nickel-iron alloys in the presence of depolarisers. Suggestions were offered to account for some of the observed facts, but a fuller discussion of their significance in connexion with the theories of over-voltage, delayed cathodic deposition, and cathodic reduction, was postponed until further information was available.

(4) "The Catalytic Decomposition of Hydrogen Peroxide Solution by Blood Charcoal," by J. B. Firth, D.Sc., and F. S. Watson, M.Sc. It was found that blood charcoal previously heated to 120° C., showed moderate catalytic activity in the decomposition of hydrogen peroxide solution, the activity being considerably increased by previous heating in a vacuum at 600° C. and 900° C. and still further by previous sorption of iodine from solution, the iodine being subsequently removed. The activity of an activated charcoal consisted of two types : α activity which was very rapid, but ceased after a few minutes, and β activity, which may persist for several hours. Both types could be increased by activation methods. In ordinary blood charcoal α activity was absent. The introduction of iron into sugar solution prior to carbonisation considerably increased the activity of the charcoal, and it was suggested that the iron acts as a spacing agent, thereby increasing the activity of the carbon itself. The velocity of decomposition varied with the concentration of the hydrogen peroxide solution. The proportion of hydrogen peroxide decomposed was determined by *both* the activity of the charcoal and the concentration of the hydrogen peroxide solution. With highly active carbons, the heat generated by the rapid decomposition of the hydrogen peroxide, raised the temperature of the reaction, temporarily, thereby maintaining the velocity of reaction at a higher level until this heat was dissipated.

(5) "The Effect of Sucrose on the Rate of Coagulation of a Colloid by an Electrolyte," by Leonard Anderson, Ph.D. The author investigated the coagulation of gold sols by hydrochloric acid, barium chloride and potassium chloride in presence of varying amounts of sucrose, and concluded that sucrose exerts a definite peptising effect upon colloidal gold, and that it exerts a specific augmentation of coagulation in the case of hydrogen and barium ions over and above that of increasing the activity of these two ions. The experiments indicate in general, however, that the coagulation power of an ion depends upon its activity rather than upon its concentration, a conclusion which brings the typical colloid phenomenon of coagulation into line with the kinetics of

chemical change in homogenous (molecular) systems.

(6) " The Properties of Powders. Part VIII. The Influence of the Velocity of Compression on the Apparent Compressibility of Powders," by E. E. Walker, D.Sc. The Influence of the duration of the load on the volume ratio of compressed powder was investigated, and the isobaric curve was correlated with the value of the ratio resistance to impact resistance to static load, and further evidence for the validity of the classification of powders suggested in Part VI of these studies obtained.

(7) " The Volumes Occupied by the Solute Atoms in certain Metallic Solid Solutions and their Consequent Hardening Effects," by A. L. Norbury, M.Sc. Cold-hammering had the effect of closing up minute blow-holes in copper. Very severe cold-hammering set up stresses and strains in the metal, which probably caused local increases and decreases in density. Otherwise cold-hammering did not affect the density. Commercial copper had a distinctly lower density than cathode copper. When an element was distributed in solid solution as single atoms replacing single atoms of the solvent in the space-lattice of the latter, the hardening effect was, in general, proportional to the difference in size of the solute and solvent atoms. The above relationship did not hold in certain exceptional cases (viz., Si in Cu and Na in Pb), which appear to arise when the solute has an exceptionally strong " chemical affinity " for the solvent. In such cases the solute probably exists in solid solution in the form of molecules of an inter-metallic compound having a different space-lattice from that of the solvent, the interference with slip and consequent hardening being relatively much greater in this type of solid solution. When an element formed a solid solution with another element, there was a certain contraction or expansion which seems to be large or small according to whether the " chemical affinity " between the elements is large or small.

(8) " A Method of Measuring the Rate of Coagulation of Colloidal Solutions over Wide Ranges," by H. H. Paine, M.A., B.Sc., and G. T. R. Evans, B.Sc. The rate of coagulation of colloidal copper solutions was studied for a wide range of electrolyte concentrations by making use of the retarding effect of starch, very rapid coagulations thus being brought into the region of observation by ordinary methods. A " transformation factor " could be obtained with which it could be calculated what the rate of coagulation would have been for the pure colloid. The results of these experiments agree closely with the equation deduced by Freundlich for the variation of the rate of coagulation with the concentration of the electrolyte. In particular, they confirm the existence of a maximum rate of coagulation. Concentrations of starch below a certain minimum do not influence the rate of coagulation.

CORRESPONDENCE

THE DISCOVERER OF ZYMASE

Sir,—Mr. Duckworth's suggestion in your issue of November 23 that zymase was discovered by Bechamp in 1864 appears to rest on a misapprehension. In the paper in the *Comptes Rendus* to which he refers (1864, 58, 601, April 4), Bechamp, it is true, uses the name *zymase*, but applies it to the agent by which yeast " transforme . . . le sucre de canne en glucose." This agent had previously been extracted from yeast and precipitated by alcohol by Berthelot (*Comptes Rendus*, 1860, 50, 980, May 28), who termed it " ferment glucosique." Bechamp's *zymase*, therefore, had nothing to do with the agent which brings about the alcoholic fermentation of glucose.—I am, Sir, etc., Arthur Harden

LINEAR v. LOGARITHMIC RATE OF CHEMICAL CHANGE

Sir,—The address given by the President of the Society of Chemical Industry to the South Wales Section, as reported in your issue of the 16th inst., raises the interesting question of linear *v.* logarithmic rate of chemical change, but I would venture to suggest that Dr. Armstrong presents only one aspect of the case. The statement is made in the report that " the first fact which has emerged from the detailed study of chemical action at a surface is that the action is not one of the so-called first order, in which the same fraction of the reacting substance undergoes change in successive equal intervals of time—a change expressed graphically by a logarithmic curve." Now, whilst this statement is no doubt true of a number of investigations of reaction velocity in presence of solid catalysts, it is by no means true of all, and I desire to emphasise the point that its validity is subject to the special conditions set out in the following sentence (taken from your report) : " when proper and sufficient care is taken to keep the surface active the rate of change is uniform, provided that the changing substance is present at the surface in sufficient quantity." Where, however, the surface is of constant activity, and the concentration of the changing substance is substantially maintained the rate of the reaction, as it seems to me, *cannot be other than linear* in character, irrespective of the mechanism of the change. The observation that the rate of change in some particular case is linear indicates merely, so far as I can judge, that a steady state is being maintained in respect of (1) the activity of the catalyst, and (2) the concentration of the real reacting substance. Such an observation, I submit, cannot by itself throw any light on the mechanism of the reaction.

On the other hand, in a reaction where the catalyst surface retains its activity, but the concentration of the reacting substance decreases with time (a case which surely merits consideration as well as the one put forward by Dr. Armstrong), the rate of change will not be linear in character. In a number of instances belonging to this category which have been examined experimentally and put on record the rate is logarithmic, and the course of the change is represented by the formula for a first order reaction.—I am, Sir, etc.,

SOLID ABSORBENTS FOR BENZOL RECOVERY

Sir,—May I thank Dr. Chaney for his criticism of my article on the use of solid absorbents for the recovery of benzol from gas? His comments are rendered only slightly less valuable by reason of his natural bias in favour of activated carbon, in the discovery and technical production of which he has played so conspicuous a part. Possibly for this latter reason, Dr. Chaney has failed to note that my article was intended to press the advantages of *solid absorbents in general* and to point to their claims to serious consideration as materials able effectively to replace oil, now generally used in the oil-washing process for benzol recovery. The fact that I devoted a considerable section of my article to a general description of the latter process, and emphasised its relative shortcomings should have been, in itself, sufficient to indicate the main theme of the article. *All* efficient solid absorbents demand attention in regard to their potential application in gas stripping and similar processes, and highly activated carbon is no exception.

The prices demanded for the activated carbons, available in this country, are high, and particularly so if their relative absorptive capacities be taken into account. I have not had an opportunity of testing the American carbon or of comparing it and its truly assessed technical value with inorganic gels, and can argue only upon my experience of English carbons. (I now have direct information that an English engineering company is hoping to work a new process for the production of a highly activated carbon, and expects to be able to produce an efficient material at a low cost. A substantial reduction in the price of a suitable carbon of high activity would materially influence any discussion on the relative merits of carbonaceous and inorganic gel absorbents. I notice, however, that Dr. Chaney gives us no idea of cost of the American carbon.)

For this reason, and this alone, I decided to illustrate the value of solid absorbents in benzol recovery by reference to inorganic gels. My broad view is indicated by the fact which, curiously enough, Dr. Chaney quotes against me, that I made use of data on the value of the solid absorbent, activated carbon, in the process of gasoline recovery from natural gas. I did not and I do not wish to place activated carbon without the pale of discussion in this general matter of the use of solid absorbents.

It would be a poor compliment to Dr. Chaney if I needed his letter to call my attention to many valuable papers on this question due to him and his associates. If I had intended to discuss the question of "Activated Carbon *v.* Silica Gel"—as Dr. Chaney heads his letter—much more space than is represented by a small section of one article would have been required. I have no intention, however, of returning to this matter, for, if the value of solid absorbents wins its rightful recognition, the technologist will soon decide for himself the question of the relative merits of carbon and inorganic gels, and will regard not only over-all efficiency and absorptive capacity per unit of cost, but also the important question of life of absorbent, space-time capacity, and all essential technical details. Inorganic gels, as the writer was fully aware, are water selective—indeed, they have been used with success for drying humid air—but they do absorb benzol from gas, and the interesting work of Dr. Chaney upon the relative selectivities of solid absorbents, whilst recognised and appreciated by the works chemist, will find its final trial in the balance sheet.

That my article was not generally misread has become evident from comments which have filtered through to me, and from the attitude taken by the reviewer in an important gas journal. The use of solid absorbents to replace oil in the process of benzol recovery from gas merits attention, and my article was intended to emphasise this general question and not to select a particular material and boom it. If I have succeeded in this, my purpose is gained.

Dr. Chaney has performed a service in advancing the discussion of the best solid absorbent to employ, but I cannot but feel that, had he been as fully acquainted with the most highly activated inorganic gels as he is with activated carbon, he would not have been so "surprised," as he claims to have been at my general treatment of the question of the use of solid absorbents for benzol recovery from coal gas and coke-oven gas. The carbonisation industries still hesitate to apply the principle of the new method, and more intimate discussion can profitably await a more general conversion to the basic process.—I am, Sir, etc.,

Rex Furness

November 24, 1923

THE DIFFICULT ENGLISH

M. the Editor.—This week, I make me the task to understand Mr. Chaney. I ask me—"What is the 'activated carbon,' indeed, what he mean by 'carbon'?" I find not in the dictionary the adjective 'activated', only 'active.' 'To activate', I see, is a verb of the much old time, used, by the Lord of Bacon, of a property, not a thing. When I read the Mr. Bone, I find it but he use it of the nitrogen and seem to say it mean 'energy-absorbing', not absorbing of the vapours. I have suspicion of the word ; it seem not of the nice english.

Mr. Furness, I see, speak of the charcoal not the diamond, which only is carbon, I suppose me. Perhaps, the 'activated carbon' is something american ? Mr. Chaney, indeed I notice, say—" Gas adsorbent charcoals are manufactured in the United States exclusively." The absorbing charcoal is long known and understood in England, I suppose. I have read much of the discovery of it by Sir Dewar and that it is used long ago in the world entire in the laboratories.

Mr. Chaney tell us—' Silica gel is hydrophilic or selective for water vapour'. Why speaks he not the american, if he likes not the english ? The so little word 'dry' would be so better than his so long sentence. The englishmen but few know the greek ; the Kakologophilic american not at all. I think, even the Mr. Coolidge, though he say it is good for him. Professor Percy Gardner, it is true, say to us in *The Times* paper, 'you know nothings because you have it not'. He is a big, simple man, I think, who *se broute*—what you say ? browse—on the so superior green lawn of Oxford ; he forget we have translate it all into the english and french more beautiful to us ; he know not perhaps we use it so much in the science that we us ourselves understand no longer and the peoples no word can read we say. We have try to make us understood for the classics men, I suppose—but as the little birds, they will not let us put the of science salt upon their tails. It is sad they live so only in the past.—Your reader most admiring of your efforts, "PARISIAN"

TO OUR PHARMACIST IN (1923+x)

SIR,—I enclose the following verses as a warning to your readers in case your leader of this week's *Chemistry and Industry* may have put queer ideas into their heads :—

Put up your shutters, and lock up your door,
Pharmaceutical Chemists are wanted no more ;
A kindly Bureau has decided to give
Drugs gratis, sufficient as long as we live.

When I sat down with Molly to breakfast to-day,
We had porridge, prepared from a packet marked "K" ;
For after November they mix with our feed,
Either Aspirin (I think) or Quinine-NH_3d.

Our tea has been treated with something they say,
To take the injurious Tannin away.
And I have a suspicion, from tests I have made,
They have kindly put Glauber's in my marmalade.

Since I filled in that form for the "Illness Bureau,"
The Inspector has saved us a chapter of woe ;
But I'm wondering still, when I see him again,
What on earth he will give for my Varicose-vein !

"ATHOS"

November 26, 1923

[It is of interest to note that, according to *Chemical and Metallurgical Engineering*, the authorities at Rochester, N.Y., have decided to eradicate goitre in the district by adding sodium iodide to the water supply, which will now contain 1 part of iodine per 1000 million of water.—ED.]

PERSONALIA

On October 30, the gold medal of the Royal Society of Medicine was presented to Prof. F. Gowland Hopkins.

Prof. F. O. Bower has been elected president of the Royal Society of Edinburgh, and the following have been elected office bearers : Vice-presidents, Major-General W. G. Bannerman, Dr. W. H. Tait, Principal J. C. Irvine, Lord Sadesen, Profs. J H. Ashworth and T. H. Beare ; General Secretary, Prof. R. A. Simpson ; Secretaries of Ordinary Meetings, Dr. A. Lauder and Prof. W. W. Smith ; Treasurer, Dr. J. Currie ; Curator, Dr. J. A. Chrichton Mitchell ; Counsellors, Profs. H. S. Allen, E. M. Wedderburn, T. H. Bryce, J. Y. Simpson, D'Arcy Thompson, Dr. J. Ritchie, Sir R. Greig, Sir J. Walker, Sir G. Whittaker, H. Briggs, W. L. Caldewood and Prof. T. J. Jehu.

The following awards have been made by the Académie des Sciences :—The Santour Prize, to Mr. L. de Forest, member of the American Institution of Radio Engineers ; the H. Wilde Prize, to Monsieur F. Delhaye, for his geological exploration in the Congo ; the Becquerel Prize, to Mr. W. B. Dawson (Canada), for his work on Tides ; the Grand Prix for Physical Sciences to Prof. L. Cayeux, for his work on Iron Minerals ; and the Hirn Prize, to Monsieur G. Eiffel, for his Aerodynamical Researches.

Dr. K. Schirmachen has assumed the direction of the Central Laboratory of the Lucius and Brüning Dye Factory at Höchst, in place of the late Prof. W. Roser. Dr. G. Haegermann, formerly manager of the Karlstadt Main Ludwig Roth A.-G., has been appointed Director of the Laboratory of the Union of German Portland Cement Manufacturers in Berlin. Prof. A. Hesse has resigned from the editorship of the *Chemische Zentralblatt*, and Prof. L. Spiegel has also resigned from the staff of that publication. The vacant places have been filled by Dr. N. Pilücke and E. Behrle.

NEWS AND NOTES

AUSTRALIA

Discovery of Silver-Lead Ore in Queensland

A new deposit of silver-lead ore described as a "second Broken Hill" has been discovered near Chillagoe, Queensland. The outcrop was approximately ¾ mile long and samples averaged 50 per cent. of lead and 50 to 70 oz. of silver. One sample of pure galena assayed 116 oz. of silver and 50 per cent. of lead. Three leases have been granted and arrangements made to treat trial loads.—(*Ind. Aust., Sept.* 6, 1923.)

CANADA

New Low-Temperature Coal-Distillation Plant

The Ford Motor Co. of Canada, Limited, is erecting a coal-distillation plant at Ford, Ontario, with an initial capacity of 400 tons per day, but intended eventually to handle 2400 t. daily. The coke produced will be pulverised and burned under the power-plant boilers, and the surplus gas (about 4000 cb. ft. per ton of coal) will be used in forging and heat-treating steel. Other products will be ammonium sulphate, creosote, benzol, gasoline and kerosene, and lubricating oils and greases, which will not be taken from the oils remaining after the recovery of gasoline, kerosene and cresote, but may be utilised later for burning as ordinary fuel oil. The amount of benzol resulting from high-temperature distillation reaches a maximum of 4½ galls. per t. of coal treated, but in low-temperature distillation, such as will be used at Ford, this amount will be increased to 12 galls. per t. and the resulting material both from a chemical and a physical standpoint will differ from gasoline obtained from petroleum only in that it will contain a larger percentage of unsaturated hydrocarbons. A large percentage of these unsaturated hydrocarbons, however, will be converted synthetically into true gasoline. Benzol production may thus reach 4800 galls. daily and it will be marketed as a substitute for gasoline. Facilities have been provided for the storage of 100,000 tons of coal on the river front. Canadian lignite and bituminous coal will be used. A similar plant on a somewhat larger scale is being erected at the River Rouge plant of the Ford Motor Co., Detroit, but the Canadian plant will be completed and in operation several months before the plant at River Rouge.—(*Can. Chem. & Met., Sept.*, 1923.)

UNITED STATES

Fuel Briquettes in 1922

Owing to the shortage of domestic coal due to the miners' strike, a new high record of production in the fuel-briquetting industry was established in 1922, the total output of briquets being 619,425 tons (valued at $5,444,926) compared with 220,476 t. ($1,812,625) in 1921. Although the total value increased, the average value per ton decreased from $9·10 in 1921 to $8·79 in 1922. Asphaltic pitch and coal-tar pitch continued to be the binders mainly used.

Scientific Research in the Iron Industry

Research in the iron industry meets with difficulties which do not occur in chemical industry proper. In the latter, processes are worked out in the laboratory, the laws governing the reactions involved are known, and each manufacturing stage is continuously under scientific control. The iron industry, however, has grown up in the course of the ages, not so much as a result of scientific research as through a very gradual accumulation of practical experience. Isolated instances of the application of research are, it is true, to be found (*e.g.*, the Bessemer process), but it is only nowadays that an attempt is being made to introduce scientific research in the iron industry, with a view to establishing the laws underlying metallurgical processes.

Against this policy is urged the costliness of research, but there can be no doubt that a generous outlook, such as is found notably in American works, would bring its own reward. Moreover, that research of a purely academic nature may prove of great commercial value is demonstrated by the etching process of A. Fry (*cf. J.*, 1921, 660 A), by means of which it has been possible to recognise stamped markings on steel even after their superficial obliteration by thieves. It is folly to call in the research worker only when something has gone wrong. Every facility should, on the contrary, be afforded him for the study of processes in normal operation, so that, by a careful accumulation of statistical data, he is at once able to detect any abnormality.

Much valuable information may be derived from "frequency curves." Take, for example, the case of a smelting process in which the metallic melt must have a specified carbon content. Analyses of a large number of consecutive melts are made, and a "frequency curve" drawn with carbon content as abscissæ, and the frequency of occurrence of different carbon contents as ordinates. The curve should fall away steeply on either side of a sharp maximum, and any irregularity is at once visible. The reliability of individual workers, including routine analysts, can similarly be checked by means of curves of this type.

The research man should be encouraged to take an interest in practical manufacturing details and may, in some cases, even be placed in charge of processes. It is certainly desirable that the same investigator who has worked out a process in the laboratory should be responsible for its inauguration on the large scale. Just as essential as scientific research itself is the collation of results obtained. The maximum of usefulness can only be attained by free interchange of observations and mutual criticism, for without exchange of ideas a certain narrowness of outlook is inevitable. Apart from works laboratories there should be a centralised institution to deal with the more general problems affecting the iron industry, and this, together with the former, should be in close touch with the work of the universities and technical colleges.—(*Stahl u. Eisen, Sept.* 13, 1923.)

BRITISH INDIA

Forecast of the Indigo Crop, 1923-24

The first forecast of the indigo crop of 1923-24 estimates the total area at 163,700 acres, or 45 per cent. less than the final estimate last year. The total yield of dye is at present estimated at 30,400 cwt., which represents a decrease of 44 per cent. on the final revised estimate of last year. The present condition of the crop is, on the whole, reported to be fair.

FRANCE

Wool Disinfection

The Central Committee for Wool in France has been studying anthrax in relation to the disinfection of wool, and proposes to start a campaign in countries which produce infected wool, as anthrax has entirely disappeared from the French flocks.

GENERAL

Preservation of Building Stone

Mr. J. Allen Howe, whose paper on "The Use and Preservation of Building Stone," is announced to be read before the London Section on Monday, December 3, is the joint author with Dr. J. Vincent Elsden, of a recently published little book, entitled *The Stones of London* (London: Colliery Guardian Co., Ltd. 205 pp.). This is a brief, but admirably concise and interesting descriptive guide to the various kinds of stone that have been used in the building of London, with selected examples, many illustrated from photographs, in which they may be seen.

"Dynalkol" in Czechoslovakia

A report has been issued by the Czechoslovak Ministry of National Defence on the use of "dynalkol," the commercial name given in Czechoslovakia to a composite motor fuel consisting of a mixture of 60 parts benzol and 40 parts alcohol, as a substitute for gasoline. This fuel, which is now being manufactured by the Czechoslovak alcohol refineries, is much cheaper than gasoline as domestic products are used in its manufacture. The present selling price is 3·50 Czechoslovak crowns per kg., in iron barrels of 170 kg., as compared with 5·40 crowns per kg. for gasoline in Prague, and "dynalkol" promises to become an important development of the domestic motor-fuel and alcohol industries.—(*U.S. Comm. Rep., Aug.* 27, 1923.)

REVIEWS

Kurzes Lehrbuch der Chemie in Natur und Wirtschaft. *By* Prof. Carl Oppenheimer. *Pp. xx*+258+862. *Leipzig: Georg Thieme,* 1923. *Price* 25*s. paper,* 29*s. bound.*

Books on the general applications of chemistry are usually written on one of two plans; either the chemical mechanism of the operations to which the science is applied is described, or references to the utility of the substances mentioned are inserted in a book on systematic chemistry. This book is of the second type. In a very interesting introduction the author states that his aim has been to write a text-book which shall be readable, and which shall show the facts of chemistry in their relation to human needs. It is thus a presentation of the facts of chemistry to such other workers in science as biologists, apothecaries, and physicians.

The first part of the book which, for a reason not specified, is separately paged, consists of an excellent introduction to general chemistry by Prof. Matula of Vienna. This section is so clearly written and so up-to-date that any chemist could read it with advantage. Crystals and crystal structure receive more attention and are better illustrated than is usual in an introduction of this size, and the chapters on structure and valency give only slight prominence to views which are rapidly becoming of merely historical interest. This part of the book should be published separately, as may, indeed, be the object of the separate paging.

The second part, on inorganic chemistry, is disappointing. The general arrangement is on the time-worn scheme of dealing with the elements in order, compounds being discussed after the free element has been dealt with. This method is suitable and necessary in dictionaries, but is scarcely desirable in a semi-popular book of this kind. Of minor matters the use of the (German) initial letter of an element or compound as an abbreviation, instead of the usual use of the formula, is very objectionable and certainly makes the book less readable. Thus S. is used for oxygen (and sulphur), St. for nitrogen, A. for ammonia and formic acid, and so on. The physiological and pharmacological properties of the substances are discussed in a useful and interesting manner, and the short historical references relieve the solid mass of chemical facts.

The author seems to be more at home in the third section, which runs to nearly 500 pages and covers the whole field of organic chemistry. The treatment is systematic and the result might perhaps have been achieved with fewer compounds as illustrative matter. The biological bias is naturally more noticeable in this section, and synthetic and natural drugs and the proteins are very effectively treated. There are also very good outlines of the organic industries such as the manufacture of soap, rubber, gelatine and dyes.

Prof. Oppenheimer is to be congratulated on a valiant attempt to deal with the general applications of chemistry on the basis of the pure science; and if the borderland workers for whom the book is intended can be induced to read it, it will be very good for them, for chemistry, and for the world in general.

P. C. L. THORNE

ORGANIC CHEMISTRY FOR ADVANCED STUDENTS. *By* PROF. J. B. COHEN, Ph.D., B.Sc., F.R.S. *Fourth edition.* PART I. REACTIONS. *Pp.* $v+423$. PART II. STRUCTURE. *Pp.* $vii=461$. *London: Edward Arnold and Co.*, 1923. *Price* 18*s. each volume.*

Probably few lecturers in advanced organic chemistry can dispense with Prof. Cohen's book. It is, in fact, the only work of its kind which can be recommended to students for the purpose of supplementing lectures, because, in effect, it is itself a compilation of lecture notes, and the student has therefore the advantage not only of filling in the inevitable gaps in his own course, but also of approaching the subject from another point of view. It has been said that, with this book in his hands, the advanced student is apt to consider that any effort on his part to prepare full notes of his lectures is superfluous, and that he is also liable to neglect his general reading. This has not, however, been the writer's experience as a teacher, for he has found that the manner in which Prof. Cohen presents his matter has always stimulated inquiry and has led advanced students to consult rather than to avoid original literature. It is true that with such an admirable series of notes in his possession the student of the lazier kind is liable to think that he has enough material for examination purposes, but this type of student has, since the war, become rarer, and, in any case, it is not difficult to deal with him. The chief disadvantage from which the book suffers is one common to all text-books dealing with a rapidly growing science; that is to say, it is out of date almost as soon as it is printed. Hence it is pleasant to find a new edition on the market so soon after the old one, and to realise that Prof. Cohen has done his best to leave out nothing of importance in the fields of modern organic research. The story he has to tell is very welcome and inspires high hopes for the future, for the most gratifying feature of this new research work is that most of it is British. Hitherto, the lecturer had shamefacedly to admit that, despite a few outstanding exceptions, organic chemistry was a German science. This did not imply any lack of appreciation of the German chemists, whose work during the past fifty years must, for ever, stand as a monument of industry and skill, but, rather, it showed that our educational institutions were not alive to the value of chemical research and that they were ignorant of, or indifferent to, the vast influence which scientific discovery had on our national existence.

All this has now changed and is still changing for the better. The size of the *Transactions* of the Chemical Society (and incidentally their cost) bears witness to the astonishing increase in British chemical research, and these volumes of Cohen's clearly demonstrate, to those who have eyes to read, the value of the work done. When it is remembered that all this has taken place within five years of the cessation of hostilities, it must be admitted that the future is promising, provided, of course, that we have the sense to utilise our new knowledge and to employ to advantage the trained brains which our educational institutions are supplying.

Among the subjects which find a place in the present edition are the theories of Lewis and Langmuir and Sir J. J. Thomson on the structure of the atom, with its application to organic chemistry by Robinson and Kermack, Lapworth, Lowry, Kenner and others. This is, perhaps, the least satisfactory portion of the book, because it is doubtful whether any useful purpose is served by burdening the students' mind with a mass of theoretical and practical detail much of which is non-proven and all of which is highly controversial. Many organic chemists consider that the Lewis-Langmuir hypothesis is not yet in a sufficiently concrete form to warrant its application to organic reactions, and that its intrusion at the present time is apt to lead to confusion, if only because its many votaries seem incapable of reaching agreement among themselves. Other work described is that of Irvine, Haworth, and Hudson on the constitution of the carbohydrates (why does this word still persist ?), the developments of Baeyer's strain hypothesis by Thorpe and Ingold, the use of Sir W. Bragg's X-ray spectograph for determining the crystal structure of organic compounds, the photochemical studies of Baly and Heilbron, and the biochemical work of Neuberg. A brief reference is also made to the newer theories of catalysis by Armstrong and Hilditch, Langmuir, Rideal, Taylor and others. In the section on stereochemistry will be found admirable accounts of the recent experiments by Senter and Drew on the Walden inversion, by McKenzie and Wren on racemisation, by Kenner and by Mills on the resolution of new forms of asymmetric molecules, and by Brady and Dunn on the inversion of the aldoximes.

As in previous editions, the volumes are well printed and the formulae are well set up and easy to follow. The third and final volume of the series is, it is understood, to appear at no distant date.

JOCELYN THORPE

According to *The Times*, Sir J. J. Thomson, the Master of Trinity, received an honorary doctorate from the Sorbonne on November 24.

LEGAL INTELLIGENCE

Damages for an Explosion at a Chemical Works. Belvedere Fish and Guano Co., Ltd., v. The Rainham Chemical Works Co.

A serious explosion which occurred on September 14, 1916, at the Rainham Chemical Works, as the result of which the adjoining works of the Belvedere Fish and Guano Company, Ltd., were practically wrecked, was recalled in the High Court on November 8, 1923, when a claim for £10,547 by the Guano Company against the Chemical Works Company was considered by Mr. G. A. Scott, Official Referee. The action was first heard in March, 1917, before Lord Justice Scrutton, who gave judgment in favour of the plaintiffs, and directed that the amount of damages due to them should be assessed by an official referee. This decision was upheld by both the Court of Appeal and the House of Lords and thus the case now came before the Official Referee.

According to the case for the plaintiffs, the defendants manufactured picric acid from dinitrophenol and the damage was caused by the explosion of large quantities of dinitrophenol and other explosives. The plaintiff company alleged that the defendant company kept and dealt with the explosives in a negligent way.

For the defendant company negligence was denied, and it was urged that the explosion occurred in the performance by them as agents of the Ministry of Munitions of the powers and duties of the Ministry. Evidence was adduced to show that the premises of the plaintiff company were absolutely wrecked. The freehold works and plant were purchased in 1915 for £21,143, and as the result of the explosion not only had the Guano Company lost those works but had to sell its depot at West Ham as it was no longer of any use.

At the conclusion of the hearing, which lasted four days, the Official Referee assessed the damages at £2,000 with costs.

The Carriage of Zinc Ash. A. Brandt & Co. and F. W. Vogel & Co. v. The River Plate Steam Navigation Co.

In the Court of Appeal on November 19, Lords Justices Bankes, Scrutton and Atkin heard an appeal (cf. *Chem. & Ind.*, May 18, p. 502) by the River Plate Steam Navigation Co. from a decision of Mr. Justice Greer holding that A. Brandt & Co., London, and F. W. Vogel & Co., Buenos Ayres, were entitled to recover damages from the appellant company (the defendants in the action) for delay in the carriage of a consignment of zinc ash from Buenos Ayres to Liverpool, and also £748 paid by Messrs. Brandt to the shipowners under protest in order to obtain delivery of the goods. After loading on the appellant company's steamship at Buenos Ayres, the zinc ash was found to be heated and the greater portion was unloaded. The ash was reconditioned, and a considerable time elapsed before arrival at Liverpool, and then Messrs. Brandt, in order to get delivery, were forced to pay £748, the cost of reconditioning the goods.

Lord Justice Bankes, in giving judgment, said he agreed with Mr. Justice Greer that Brandt & Co. had a cause of action against the shipowners because their offer, as holders of the bill of lading, to take delivery of the goods was accepted by the shipowners. That created a contract which included all the terms of the bill of lading, so far as they were applicable at the time of delivery. The goods were damaged by rain before shipment, but the fact that the shipowners gave a clean bill of lading, acknowledging that the goods were shipped in good order and condition, estopped the appellant company from alleging that the damage to the goods was caused before shipment and prevented them relying upon exceptions in the bill of lading which might otherwise have protected them. Furthermore, proper examination of the goods during unloading and on shore would have shown that a mistake had been made as to the extent of the goods damaged. The appeal, therefore, failed and was dismissed with costs.

REPORTS

Report on the Financial and Industrial Conditions in Chile. *Dated April*, 1923. *By* J. M. Macleod, H.M. Consul-General, Valparaiso. *Department of Overseas Trade. Pp.* 6. *London: H.M. Stationery Office*, 1923. *Price* 2s.

Chilean resources are mainly agricultural and mineral, though during the past few years efforts have been made by the Government to foster manufacturing industries. The principal wealth of the country is nitrate, which provides 75 per cent. of the total revenue. Owing to the wide range of latitude, practically every kind of agricultural product is grown, and growers are in the ordinary way assured of a ready market in the mining areas, though the bad state of the mining industry has recently reduced this market. At present sugar is obtained from Peru though efforts are being made to establish a home industry.

The coal found in the country is of good quality, and supplies about half the demand, the remainder being imported from the United States, the United Kingdom, and Australia. In 1921, 477,752 tons were imported in all. In 1922 the following copper exports were made: bars and ingots, 53,425 t.; ore, 69,248 t.; gold, silver and copper ores, 1,172 t.; copper matte, 324 t. In 1922 there was renewed activity in the copper industry, large increases in output being arranged for. The important borate of lime deposits are worked entirely by an English firm; exports in 1922 amounted to 49,482 t. Iron ore, both magnetite and haematite, occurs in large deposits, though at present these are worked only to a limited extent. About 300,000 t. were exported in 1921. Though some encouragement has been given by the Government toward the establishment of a siderurgical industry, conditions are not suitable.

Trade in 1921 and 1922 was extremely weak (*cf. J.*, 1922, 270 R). The complete absence of demands for nitrate was chiefly responsible, but the drop in values of agricultural produce also had its effect. A reduction of imports, which in itself could have been advantageous was offset by a more than proportional drop in exports. The value of imports in 1921 was about £28,598,000, about 20 per cent. less than in 1920. Great Britain has regained her position of approximate equality with the United States, each sending imports worth about £7¾ millions.

A special annex deals with the nitrate industry The production from July 1, 1921, to June 30, 1922, was 1,071,297 t., against 2,772.254 t., in 1913. Exports for the year amounted to only 502,481 t., of which about 50 per cent. went to the United States.

Report on the Economic Conditions in Angola (Portuguese West Africa). *Dated March*, 1923. *By* A. B. Hutcheon, H.M. Consul-General, Loanda. *Department of Overseas Trade. Pp.* 42. *H.M. Stationery Office*, 1923. *Price* 1s. 6*d*.

Angola is essentially an agricultural country, its range of altitude permitting the cultivation of European as well as tropical crops. The most important crop is coffee. Oil-palms occur extensively, but recent neglect of the plantations has led to diminished production and the Government has had to take steps to organise the industry. The importance of rubber has decreased of recent years but sugar production has increased.

Apart from diamonds, the mineral resources of the country have been developed only on a small scale, though companies of various nationalities hold prospecting concessions for minerals and oil, and the copper mines at Bembe, long disused, are to be developed again. Prospecting rights are also being granted for coal, which occurs on the Benguella plateau. Some attention is being given to the possibility of developing further the water-power resources of the country.

The principal exports include maize, coffee, palm-kernels, sugar and wax. Imports are derived principally from Portugal, Germany, the United Kingdom, and the U.S.A. Cotton goods are in demand, whilst iron and steel goods are also imported, principally from the United Kingdom and Germany. The influx of Europeans has led to a demand for building materials, cement being the most important of these. The coal imported is obtained almost entirely from the United Kingdom.

COMPANY NEWS

ELECTROLYTIC ZINC COMPANY OF AUSTRALASIA, LTD.

After writing £20,000 off investigational research and general development account and carrying £90,000 to reserve for depreciation, the gross profit for the year ended June 30 was £401,808 (£93,841 for the previous year, during which the plant was only in operation for seven months.) After adding £2,614 for income from property and sundry receipts, and deducting profit and loss items including £48,000 as provision for income tax, the net profit was £285,406. The available balance (including £76,593 brought forward) of £361,999 has been disposed of as follows :—Writing off preference shares and debenture issue expenses, £74,482 ; by providing for co-operative council activities at Risdon, £7,500 ; carried to debenture sinking fund reserve, £12,640 ; carried to equalisation reserve, £40,000 ; and by the payment of dividends Nos. 1 and 3, £149,115, leaving a balance of £78,262 to be carried forward. The plant was completed during the year, and arrangements are in course to provide further installations which will ensure liberal supplies and enable a reserve to be accumulated. The output for the year was 31,283 tons electrolytic zinc, and silver-lead containing 4,344 t. lead and 691,052 oz. silver.

NORTH BROKEN HILL, LTD.

The profit and loss account has been credited with the sum of £673,521, made up of £597,215 for mine production, £48,190 for adjustment in respect of production previous period. and £28,116 for interest, rent and dividends. After deducting expenses, etc., a balance remains of £284,780, which, together with £30,000 (the balance forward), has been appropriated as follows :—Dividends Nos. 52 to 54, in all 6s. per £1 share, £180,000 ; debenture sinking fund, £13,333 ; appropriation for plant expenditure, £52,000, leaving a balance of £69,447. Surplus liquid assets, excluding shares and debentures in other companies valued in the balance-sheet at £448,525, amount to £532,454.

CASSEL CYANIDE CO., LTD.

The directors of the Cassel Cyanide Co., Ltd., having considered the accounts for the year ended September 30, 1923, recommend the payment of a final dividend of sixpence per share, making with the interim dividend paid in June last, ninepence per share for the year, less income tax at 4s. 9d. per £. It is proposed that this dividend be paid on December 17 to all shareholders on the register on November 20.

CELLULOSE HOLDINGS AND INVESTMENT CO., LTD.

The first ordinary general meeting was held on November 16, the chairman, Mr. A. W. Tait, C.B.E., presiding. The net profit from May 4, 1922, the date of incorporation, to June 30, 1923, was £6182, from which was deducted £1822, payable to debenture holders. The net profit accruing to the shareholders was £4359, of which £3825 would be used to write off preliminary formation and new issue expenses, leaving £534 to be carried forward.

The company took over arrangements made by Dunn, Fisher and Co. with the British Cellulose Co. for supplying further working capital required by that company, and subscribed for £500,000 8 per cent. first mortgage debenture stock and took over £750,000 participating preference shares in the British Cellulose Co., together with a royalty agreement with the manufacturing company under which the holdings company was to receive 2½ per cent. on the net sales up to an agreed figure, and 1 per cent. thereafter. To purchase the generating station at Spondon the holdings company surrendered to the manufacturing company £200,000 of the debentures which it had subscribed, and resold the power-station to the Midland Counties Electric Power Supply Co., Ltd., for £100,000 in cash, and £225,000 fully-paid ordinary shares in that company.

Early in 1923 the holdings company subscribed a further £400.000 7 per cent. first mortgage debenture stock out of a total authorised issue of £1,000,000. The holdings company now holds £700,000 of this debenture stock, the balance to be issued by the manufacturing company at its discretion for the general purposes of the company. Interest on the first mortgage debentures is to be reduced from 8 per cent. to 7 per cent., but instead of being repayable at any time after 1927 at 105 per cent., the debentures are only redeemable by means of a cumulative sinking fund, commencing at that date, at £110 per cent. The royalty on sales from July 1, 1923, is increased to 3 per cent. on net sales up to £3.000,000 per annum, and 1 per cent. thereafter for 25 years from the date when the royalty amounts to £90.000 in any one year. The holdings company issued £500,000 7 per cent. participating first mortgage debenture stock, and 998,000 ordinary shares of 1s. each, to enable the original financial arrangements to be carried out. The company now holds £700,000 7 per cent. first mortgage debenture stock of British Celanese, Ltd. : £750,000 Participating 7½ per cent. preference shares of British Celanese, Ltd. ; £225,000 ordinary shares in Midland Counties Electric Power Supply Co., Ltd. ; and a royalty agreement with British Celanese, Ltd. The company has issued £750.000 7 per cent. participating first mortgage debentures redeemable at 120 per cent., and 1,060,500 ordinary shares of 1s. each.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Nov.* 22.)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Austria ..	High grade steels ..	567
British India	Wrought iron piping ..	*
,, ,,	Caustic soda, copper and brass, sheets, etc. ..	*
Canada ..	Pottery	560
,, ..	Tools, cutlery, hardware	561
Egypt ..	Paper, Bristol board ..	11832/F.E./M.C./2
New Zealand	Plate girder spans (tender)	12569/E.D./E.C.
,, ,,	Galvanised earthrods ..	12573/E.D./E.C./2
United Kingdom	Lead cable, zinc, copper and bronze wire, lead, tin, brass, etc. (tender)	†

* The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1.

† Postmaster-General, General Post Office, E.C.1.

TARIFF CUSTOMS EXCISE

Egypt.—Revised tariff valuations have been issued, for use in assessing import duties on copper, brass, tin, lead, zinc articles, and on phosphor bronze, antimony and mercury.

Nicaragua.—The reduction of 25 per cent. of the customs duties accorded to France will, after December 1, be extended to similar goods of British manufacture.

Nigeria.—Export duties on palm kernel oil, palm oil, palm kernels and ground-nuts have been reduced.

Poland.—A manipulation fee of 5 per cent. of the Custom duty is payable, in addition to the duty, on various goods, not including coal, brown coal, charcoal, peat coal, briquettes, coke and peat. The export "manipulation" fee is 10 Polish mk. per kg., the minimum charge being 10,000 Polish mk. on each consignment.

INTERNATIONAL CUSTOMS CONVENTION

The issue for November 15 contains the sixteen operative clauses of the International Convention on the Simplification of Customs Formalities, which was signed at Geneva, on November 3, by the representatives of twenty-two States.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Germany having repudiated her reparations agreement, and consequently having defaulted in providing the 26% levy on exports to Britain which has been ruling for the last 2½ years, there has been a general rise in those chemicals which have of late been largely imported from the Continent.

The heavy chemical market maintains a steady tone, both home trade and export continuing to take tolerably satisfactory quantities. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry. Small stocks held by importers.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton. Poor demand.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal. German charcoal is again being offered.

Acetate of Lime—	
Brown	£14—£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Competition being met with.
Solvent	6s. per gall. 40% O.P. Fair demand.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s.—1s. 1d. per lb. Weaker, with limited demand.
Crude 60's	3s.—3s. 3d. per gall. Limited business for spot delivery. No market for forward delivery.
Acid Cresylic—97/99	2s.—2s. 2d. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall.

Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d.—10d. per gall. Quiet.
Unstrained	9d.—9½d. per gall. Quiet.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s, 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Good business being done.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 2d. per gall. Fair demand for export.
Solvent 90/190	1s. 2d.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 per ton.
Flaked	£19 per ton.
Pitch, medium soft	125s.—135s. per ton, according to district and time of delivery. Little business.
Pyridine—90/140	21s.—23s. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 8d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilio	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 8d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 7d. per lb. d/d. Drums extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. 6d. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The shortage of spot supplies of a number of products continues and the market remains extremely firm.

Acid, Acetic 80 % B. P.	£48 per ton.
Acid, Acetyl Salicylic	3s. 7d.—3s. 9d. per lb. In strong demand. Makers fully occupied.
Acid, Benzoic	B.P. quality almost unobtainable.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5%, for ton lots. Dearer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d. per lb. Very firm market.
Acid, Tannic	3s. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5 %. Firmer.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 9d. per lb. Small stocks. Strongly held.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. 3d. per lb. for English make.
Atropine Sulphate	12s. 6d. per oz. for English make. Demand very poor.
Barbitone	17s. 6d. per lb.
Benzonaphthol	4s. 9d. per lb. Weaker.
Bismuth Salts	A steady market. Prices according to quantity :
Carbonate	12s. 9d.—14s. 9d. per lb.
Citrate	11s. 4d.—13s. 4d. ,,
Salicylate	10s. 2d.—12s. 2d. ,,
Subnitrate	10s. 9d.—12s. 9d. ,,

Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	Remain very firm. Continental prices advancing
Potassium	8d.—9d. per lb.
Ammonium	9d.—10d. „
Sodium	8½d.—9½d. „
Calcium Lactate	2s. 9d. per lb. for best English make.
Chloral Hydrate	4s. 3d. per lb. Position very firm.
Chloroform	2s. per lb. for cwt. lots. More active.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 13s. 6d. per lb.
Hexamine	4s. 6d. per lb. Very firm market. Spot supplies decreasing.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	1s. 11d.—2s. 3d. per lb., according to quality.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£72 10s. per ton, less 2½%. Reduced by £5 per ton.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. „
White precip.	4s. 6d.—4s. 8d. „
Calomel	4s. 1d.—4s. 3d. „
Methyl Salicylate	2s. 11d. per lb. for carboys. Brisk market. Higher values expected.
Methyl Sulphonal	23s. per lb. Small supplies.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 7d. per lb.
Phenacetin	7s. 6d. per lb. Steady market.
Phenazone	8s. 9d. per lb. In short supply.
Phenolphthalein	8s. per lb. Very firm.
Potass. Bitartrate—99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Permanganate	9½d. per lb. for B.P. crystal.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Salol	4s. per lb. Supplies more plentiful.
Silver proteinate	10s. 6d. per lb. Quiet.
Sod. Benzoate	3s. 6d. per lb. Very scarce.
Sod. Citrate, B.P.C., 1923	1s. 5d.—1s. 9d. per lb., according to quality.
Sod. Hyposulphite—Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 11d. per lb., and Crystal at 3s. per lb. Firm and very active.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb., according to quality.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	13s. 6d. per lb. quoted for synthetic and 14s. 6d. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. „ „
Amyl Acetate	3s. „ „
Amyl Butyrate	7s. 3d. „ „
Amyl Salicylate	3s. 6d. „ „
Anethol (M.P. 21/22° C.)	3s. 9d. „ „
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. „ „
Benzyl Alcohol free from Chlorine	3s. 3d. „ „
Benzaldehyde free from Chlorine	3s. 3d. „ „
Benzyl Benzoate	3s. 6d. „ „
Cinnamic Aldehyde Natural	22s. 6d. „ „
Coumarin	20s. „ „
Citronellol	19s. 6d. „ „
Citral	9s. 6d. „ „
Ethyl Cinnamate	10s. „ „
Ethyl Phthalate	3s. 9d. „ „
Eugenol	11s. „ „
Geraniol (Palmarosa)	37s. 6d. „ „
Geraniol	6s 9d. to 13s. 6d. per lb.
Heliotropine	8s. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	20s. „ „
Linalyl Acetate	20s. „ „
Methyl Anthranilate	8s. 6d. „ „
Methyl Benzoate	6s. „ „
Musk Ketone	47s. 6d. „ „
Musk Xylol	13s. 6d „ „
Nerolin	4s. „ „
Phenyl Ethyl Acetate	10s. „ „
Phenyl Ethyl Alcohol	16s. „ „
Rhodinol	60s. „ „
Safrol	1s. 10d. „ „
Terpineol	3s. „ „
Vanillin	24s.—25s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 11d. „ „
Bergamot Oil	13s. 3d. „ „ spot.
Bourbon Geranium Oil	37s. „ „
Camphor Oil	75s. per cwt.
Cananga Oil, Java	9s. 6d. per lb.
Cinnamon Oil, Leaf	5d. per oz.

Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 9d. „ „
Ceylon	Very little on offer.
Clove Oil	10s. 6d. per lb.
Eucalyptus Oil 70/75%	2s. 6d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil	2s. 10d. per lb. Higher prices expected.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil	24s. 6d. per lb.
Peppermint Oil—	
English	70s. per lb. Market very unsteady.
Wayne County	15s. 6d. per lb. Market very unsteady.
Japanese	12s. 6d. per lb. Market very unsteady.
Ptitegrain Oil	8a. 9d. per lb. Dearer.

TRADE NOTES

Midland Bank, Ltd.

The shareholders of the London Joint City and Midland Bank have confirmed the resolution changing the name of the company to Midland Bank, Limited. The new title will be effective as from Tuesday, November 27. Existing share certificates at present in the hands of shareholders are not being exchanged for fresh certificates bearing the new name.

The German Iron and Steel Industry, 1913-1920

The number of blast furnaces in Germany in 1920 showed a decrease compared with the figure for the previous year, and more markedly with that for 1913. The causes lie in the decreased use of pig-iron; although, owing to greater output per furnace, more pig-iron was produced in 1920 than in 1919, the total did not then reach the 1913 figure. The following table gives some particulars of the industry :—

	1913 (*a*)	1913 (*b*)	1917 (*b*)	1919 (*b*)	1920 (*b*)
Works in operation	93	75	71	69	63
Furnaces existing at end of year	330	238	242	232	228
Do. in operation	313	221	203	152	146
Total No. of weeks worked	15,130	10,555	9,363	6,514	6,504
Consumption in 1000 t. of ore, slag, and flux	47,597·5	28,930·6	23,357·0	15,355·6	16,931·9
Do. coke and charcoal	19,123·7	12,925·7	10,818·3	7,716·5	8,094·3
Production in 1000 t. :—					
Total	16,763·8	11,528·9	8,703·3	5,654·2	6,387·6
Pig iron	3,374·8	2,639·7	1,618·6	1,372·5	1,324·0
Cast iron	104·5	7·0	1·3	—	—
Bessemer pig-iron	375·4	375·4	139·6	61·0	64·2
Thomas pig-iron	9,867·6	5,512·6	4,250·2	2,593·6	3,006·2
Steel, etc.	2,550·7	2,550·6	2,497·5	1,521·4	1,862·8
Puddled iron	463·9	441·6	195·7	104·6	130·2
Scrap iron	26·9	1·8	0·5	1·2	0·3

(*a*) Pre-war Empire. (*b*) Within present boundaries, excluding Saar.

The relative quantities of the different varieties of pig-iron have changed greatly. The smaller production of Thomas pig-iron was caused by the decrease in the use of phosphorus-bearing ores, whilst the production of steel increased owing to the extended use of the Martin process.

Market News from France.

The metal market became still weaker during the month, and quotations were greatly reduced, without, however, leading to any increased demand.

The turpentine and resin harvest is now over, so prices are firm and standing 10 frs. higher at 500 frs. on November 19. Resins are quoted higher owing to the demand by soap boilers, especially for the better qualities, which are becoming scarce.

The German Wrought Iron Industry

Whereas in 1890 about one-half of the steel made in Germany was obtained from wrought-iron (" schweisseisen "), since then its production from this material steadily decreased till the outbreak of war, mild steel being used instead. Since the war the decrease has continued. In 1920, in spite of a decrease in the number of furnaces alight, the production of wrought-iron increased from 3200 tons to 54,003 t. That the industry is losing its importance is shown by comparison of these figures with the output for 1913, viz., 199,000 t.

German Reparation (Recovery) Act

By a decree of the German Government, dated November 15, all payments for the reimbursement of the levy under the German Reparation (Recovery) Act, 1921, are suspended. The decree came into force on November 17 and contracts concluded before this date are excluded from its provisions, provided the contracts are notified to the " Friedensvertrag-Abrechnungsstelle G.m.b.H. Charlottenburg, Berliner Strasse 17," before December 1, and a certified copy of the contract is enclosed. In the case of such contracts, the amount of the levy will be reimbursed provided that the British Customs receipt is presented to the " Friedensvertrag-Abrechnungsstelle " by March 31, 1924. The German Government reserves the right to reimburse in cash or in loan or other Government obligations.

Exports of Copra and Rubber from Java

H.M. Commercial Agent at Batavia reports that exports of copra from Java and Madura in 1922 were 53,233,000 kg., as compared with 93,009,000 kg. in 1921, whilst during the March quarter of 1923 exports amounted to 13,187,000 kg. as against 11,543,000 kg. in the corresponding quarter of 1922.

Exports of rubber in 1922 and 1921 amounted to 31,659,000 kg. and 29,400,000 kg. respectively whilst during the March quarter of this year they amounted to 8,561,000 kg. as against 6,980,000 kg. in the March quarter of 1922.

Canadian Output of Non-Metallic Minerals in 1922

The Dominion Bureau of Statistics issues the following finally revised statistics on the production of Non-Metallic Minerals in Canada during 1922. With the exception of arsenic there were no outstanding differences between the production of 1922 and the previous year of the commodities listed below as miscellaneous non-metallic minerals. The production of arsenic increased by 42 per cent. as compared with 1921. Large quantities of this product are being used in the United States to make insecticides for combating the cotton boll weevil.

		1922.

An Improved Ozonizer

The usual form of ozonizer in which air or oxygen is passed through an annular tube, between the walls of which a silent discharge is passed has recently been improved by A. Starker, of Danzig. The apparatus is essentially the same as at present, but instead of the usual discharge frequency of 50-100 periods per second one of about 10,000 is used. The yield, about 10 per cent., is no higher than that obtained at present, but a larger volume of gas can be treated with an apparatus of a given size, so that overhead costs are considerably reduced.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES — LONDON, DECEMBER 7, 1923 — No. 49

EDITORIAL

BY the time this issue appears a large number of election results will be known, and we shall be able to have some idea as to the nature of the Government which will guide our destinies for the immediate future. Our readers will naturally and properly hope that nothing will be done which will harm the great industry with which we are connected. The merits of Free Trade and of Protection have been hotly debated, and from isolated statistics during brief and exceptional periods many unjustified deductions have been drawn. Scientific men should be cautious in drawing conclusions from imperfect data, and one of them, Huxley, has pointed out the sort of error which may result. " Robinson Crusoe," he said, " did not feel bound to conclude, from the single human footprint which he saw in the sand, that the maker of the impression had only one leg." If we look back during the last few hundred years, not only in this country, but in many countries, we find that both tariffs and free imports have been tried, not once or twice, but repeatedly in several, and the results neither justify the golden hopes offered by their advocates nor the gloomy forecasts of ruin which the opponents prognosticate. The country adapts itself to new conditions, and so long as the dislocations to trade are not too sudden and too fundamental, the adaptation takes place without inflicting irreparable damage on a large proportion of the population. There is no indication at the moment that any political party will have the power, even if it have the desire, of making any calamitous dislocation in our industrial and commercial conditions.

A general election during a spell of cold and unpleasant weather has made many of us discontented and inclined to be critical. Even chemists, notwithstanding the philosophical remarks of Dr. E. F. Armstrong, have grumbled at the slow progress of civilisation, at their distant prospect of making a fortune, at the lack of courage of the Federal Council, of the Chemical Society, of the Society of Chemical Industry, and even at the dulness of this Journal. Be of good cheer. If winter comes, can spring be far behind ? Those who investigate whether 'tis folly, pride or knavery that makes this discontented land appear less happy now in times of peace than war, may reflect that wise men affirm it is the English way never to grumble till they come to pay. Is not this the prime cause of the troubles of our chemical organisations as well as of the nation ? We know there are some people, even among the chemists, who are critical by disposition and who would say to our great metropolis : " Let but thy wicked men from out thee go, and all the fools that crowd thee so, even thou who dost thy millions boast, a village less than Islington will grow, a solitude almost." Some of us would rather see London as it is than distilled, filtered, and fractionated to such a degree of purity. We cannot all be as wise as Nestor, wisdom cannot be passed from one having it to another not having it We suffer, perhaps, from too much liberty ; of all the nations in the universe, none can talk on't more, or understand it less. This has been a year of difficulties and troubles, most of them already overcome. Even editors have their disqualifications; did not Dr. Johnson say, no man is appointed to an office because he is the fittest for it? We refuse to be discouraged, and indeed such advances have been made during the last year or so that chemists have no right to be other than proud and happy.

* * *

Science has conferred innumerable material benefits upon humanity, and this very utility has served to obscure its finer qualities from those without the pale. Without doubt, wireless, underground railways, tinned milk and denicotinised tobacco will provoke the scorn of the æsthete, and the modern poet who wrote of how he "saw sweet Poetry turn troubled eyes on shaggy Science nosing in the grass" is quite typical of a common attitude towards research, but few who have had no scientific training have troubled to inquire into its intellectual significance. Chemistry has certainly been subject to more than a fair share of misunderstanding, though it is true that the atomic theory has attracted speculative minds throughout the ages and our present Poet Laureate has questioned "whether each element is a coherency of equal Strictly symmetric atoms, or among themselves the atoms are Like animals in a herd, having each an identity distinct."

If chemistry is really misunderstood, it is in part the fault of its highly-specialised terminology, and this difficulty is further increased by the general indifference to the use of plain, perspicuous English. It was thus with no surprise that we read, in a paper recently set for the "school-leaving examination," the requests: "Define the terms deliquescent and efflorescent, naming, with their formulæ, two examples in each case"; "State exactly what you would *observe* in each of the following cases and what tests you would apply to each in order to show that reaction had taken place,"—*e.g.*, "Ammonia and chlorine gases are brought into contact"; "Describe and *explain* as far as you are able the appearance presented when copper turnings and sulphuric acid are heated together in a flask." The italics are not ours, but the "appearance presented" by the paper had it been properly revised "in the case of" at least five out of eight questions would have shown that "reaction *had* taken place." It is long since Newman wrote that "thought and speech are inseparable; matter and expression are parts of one," but the recent taunt, Is it consonant with the high dignity of science to make her talk like a cheap showman? remains unchallenged. The wording of examination questions may have a dire effect on the candidate, and it is but reasonable to ask that his psychological processes, already strained, be not unduly disturbed.

LOW - TEMPERATURE TAR FROM BITUMINOUS COAL

By JEROME J. MORGAN, M.S., Ph.D.

When coal is heated out of contact with the air but at about atmospheric pressure, a point is finally reached at which decomposition, as evidenced by the rapid evolution of gases and vapours, becomes marked. This is the temperature of the formation of primary tars, and varies for different coals. According to L. C. Jones[1], this temperature ranges from 230° for brown lignites to 330° for bituminous coal. Apparently, it varies inversely with the oxygen content of the coal. In ordinary high-temperature carbonisation, either in the coke oven or in the gas retort, the vapours of this primary tar are heated in contact with the hot coke and walls of the chamber to temperatures of from 800° to 1100°. At these temperatures the compounds of the primary tar are cracked and yield gases, and the secondary or high-temperature tar with which we have long been familiar. It is only recently that new methods of carbonisation have made available commercial quantities of primary or low-temperature tar, and regarding its nature there has been a great deal of speculation and misunderstanding. In presenting a few facts which may help to clear up this misunderstanding, the writer will limit himself to such tar obtained from bituminous coal.

Processes for Low-Temperature Carbonisation

It is not the intention of the writer to go into details regarding the various processes of low-temperature carbonisation. Almost every possible form of apparatus has been tried or proposed, ranging from heating a thin layer of coal in a large intermittently-charged muffle to floating the powdered charge on the surface of a molten metal bath. Without attempting to make a complete classification, the following may be mentioned as representative processes:—

German Processes.—The Thyssen rotating horizontal retort[2] somewhat resembles a cement kiln and has been used for brown coals. The Ehrhardt and Sehmer process[3] distils the coal in rotating vertical retorts which are situated in the top of a modified Mond gas-producer and through which a portion of the producer-gas is diverted to heat the coal and sweep out the products of distillation. The Pintsch process[4] proposes to combine the recovery of low-temperature tar with the consumption of the semi-coke under the steam boiler. A portion of the hot combustion gases is used to pass through the carbonising chamber.

[3] Pamphlet of Aktiengesellschaft für Brennstoffvergasung, Berlin NW 40, Roonstrasse 4.

[4] A. Faber, *Z. angew. Chem.*, 36, 12 (1923).

English Processes.—The improved Coalite process[5] makes use of an intermittent vertical retort in which thin layers of coal are held against the sides of the retort by a pair of movable perforated iron plates. The MacLaurin process[6] employs a tall producer, but only enough air is used to burn about one-third of the coke. The hot producer-gas formed at the bottom passes up through the fuel column and distils the coal in the middle section. At the top the oils are deposited on the cool fuel and tapped off. The Mond gas-producer has been modified by the Power Gas Corporation[7] so as to combine low-temperature carbonisation with the recovery of ammonia and the production of gas.

Processes in the United States.—The Carbocoal process[8] utilises a cardioid-shaped horizontal carborundum muffle through which the coal is advanced by twin paddle shafts so constructed that the paddles mutually clean themselves of the sticky fused coal. The Parr-Layng process[9] proposes to control and employ the exothermic decomposition of certain high oxygen coals to transfer heat to the centre of the charge in a coke oven. In this way it is expected that low temperature conditions will be maintained and the cracking of primary tar avoided. Finally, the Doherty complete gasification process[10] combines the recovery of low-temperature tar with the production of producer and blue gas. This process promises in the near future to give us a very large supply of low-temperature tar.

Comparison of yields of products, and especially comparison of the quantity and character of the tars from these different processes, is a dangerous proceeding and likely to lead to wrong conclusions. This is true because, in the first place, the processes have not been tried on the same fuels, and, second, because the main objects of the processes have usually been different. Then, too, there have usually been minor operating conditions which render such comparisons unfair and misleading. It will only be when the processes are compared by the standard of the best economic results from a given fuel and under a given set of conditions that the comparison becomes fair. Such a comparison has never been made, and certainly cannot be made from the data now available in the literature. In treating the question of low-temperature tar, therefore, it is proposed to review the information about the tar which has been most thoroughly investigated—namely, carbocoal tar.[11] We may then infer to some extent how other low-temperature tars will differ from this.

COMPOSITION OF CARBOCOAL TAR FROM BITUMINOUS COAL

The coal used in producing the carbocoal tar in question was the Pennsylvania gas-coal which is known as "Pittsburgh Terminal" and which, analysed on a dry basis, contained, per cent., volatile matter 35·3, fixed carbon 57·9 and ash 6·8. In the carbonisation the coal was exposed for three hours to a temperature of 500° to 600°. The yield of crude dry tar amounted to 11·3 per cent. of the weight of the coal, or about 25 gallons per ton. The composition of this tar along with tars from coke ovens and gas retorts is given in Table I.

TABLE I

Comparison of Carbocoal Tar with High Temperature Tars

	Carbo-coal	Coke oven	Gas works
Crude, dry tar—			
Sp. gr. 15·5/15·5	1·0676	1·1845	1·2172
Free carbon, per cent.	0·71	6·93	20·1
Distillate, per cent. by weight			
up to 170°	0·64	0·70	1·19
170—230°	9·19	8·27	9·22
230—270°	12·50	12·44	10·12
270—300°	6·94	6·21	3·78
300—310°	2·90	2·53	1·93
Pitch by difference	67·83	69·85	73·76
Sp. gr. 15·5/15·5	1·134	1·263	1·312
Free carbon, per cent.	2·17	16·8	31·1
Air melting point, ° C.	53	69	89

The results of further examination of the distillate of this tar by a scheme of analysis developed in the course of the investigation of its composition[11] are given in Table II.

TABLE II

Composition of the Distillate from Carbocoal Tar

	Percentage by weight on the basis of	
	Distillate	Crude, dry tar
Phenols	42·7	13·7
Nitrogen bases	1·9	0.6
Hydrocarbons	55·4	17·8
Cyclic unsaturated	41·5	13·4
Saturated	13·9	4·4
Naphthenes	8·8	2·8
Paraffins	5·1	1·6

CONSTITUTION OF THE COMPOUNDS IN CARBOCOAL TAR

Phenols.—The composition of the tar acids from the distillate of the tar is given in Table III, in which the large percentage of phenols with boiling points higher than the xylenols is to be noted.

A comparison of the distillation curves for the carbocoal tar acids and the mixed tar acids from coke-oven and gas-works tars is given in Figure 1. From the shape of the curve it is evident that the low-temperature phenols are a mixture of a large number of compounds with gradually-increasing boiling temperatures.

The flattened portion of the other curve is due to the preponderating amounts of phenol and the cresols in the high-temperature tar acids.

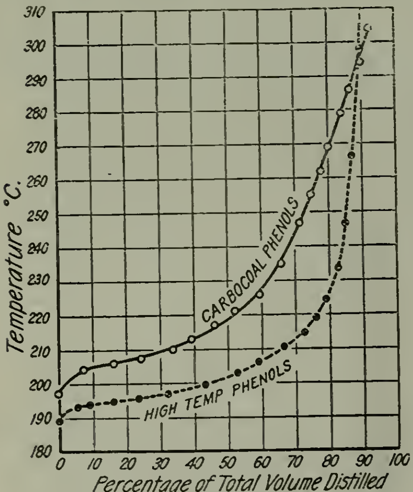
TABLE III

Composition of Carbocoal Tar Acids

	Percentage by weight on the basis of		
	Tar acids	Distillate	Crude tar
Phenol	4·2	1·9	0·6
Cresols (*a*)	33·4	15·2	4·9
Xylenol fraction	19·0	8·7	2·8
Higher homologues	34·8	15·9	5·1
Pitch (acid resins)	8·6	3·9	1·3
Totals	100·0	45·6	14·7

(*a*) Ratio: 27% ortho-, 19% meta- and 54% para-cresols.

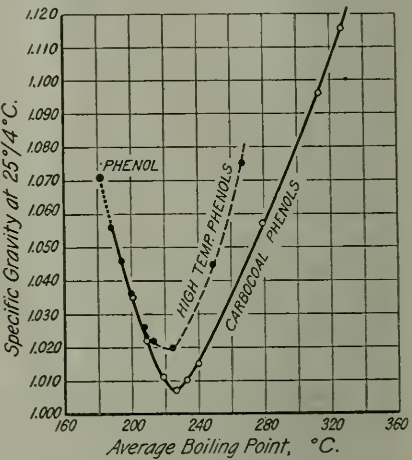
Considerable information about the nature of the tar acids can be obtained from a study of the curves showing the relation between the gravity and boiling points of the fractions. These curves are given in Figure 2, and from them it is seen that the lower boiling phenols are the same in both low and high-temperature tars. The lower density of the high-boiling phenols of the carbocoal tar is partly due to the presence of alkyl side chains and partly to extra hydrogen in the ring in these compounds. In the high-temperature tars these side chains and the hydrogen are split off with the formation of simpler phenols having a higher density for the same boiling point. Not all the phenols of low-temperature tar, however, are thus converted into the simpler phenols of high-temperature tar. In a considerable portion of these compounds the hydroxyl as well is split off with the formation of hydrocarbons, or the ring may be ruptured, giving rise to gas and carbon.



DISTILLATION OF PHENOLS

FIG. 1

Nitrogen Bases.—The nitrogen bases of carbocoal tar were found to consist of 20 per cent. of secondary bases and 80 per cent. o tertiary bases. Primary bases were absent. Comparison of the boiling point—specific gravity curve for these bases with that for high-temperature bases shows a similar state of affairs as in the case of the tar acids. There is no predominating low-temperature base to correspond to quinoline in high-temperature tar. Also, the lower density of the low-temperature bases points to the presence of side chains and extra hydrogen in the ring.

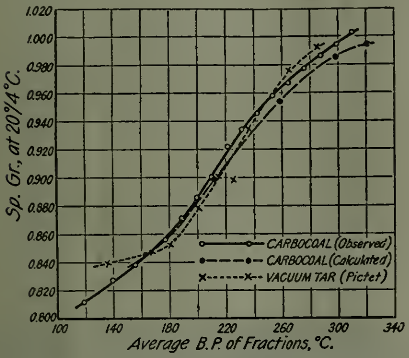


BOILING POINT—SPECIFIC GRAVITY OF PHENOLS

FIG. 2

Neutral Oils.—As was shown in Table II, the neutral oils of carbocoal tar are about three-quarters cyclic unsaturated compounds. The saturated hydrocarbons, which comprise less than 5 per cent. of the tar, are only about one-third paraffins. The remainder of the saturated hydrocarbons are naphthenes. Aromatic hydrocarbons are absent or, at most, present only in traces. No solid compounds separated even when the neutral oil was cooled to –35°. The boiling point—specific gravity curve for the unsaturated hydrocarbons is given in Figure 3, and for the saturated hydrocarbons in Figure 4.

With reference to the curves in Figure 4, it is interesting to note that the saturated hydrocarbons from carbocoal tar are very similar to those from a kerosene made from mid-continent crude. It is also noteworthy that the higher boiling portions of the saturated hydrocarbons from the kerosene contain more naphthenes than paraffins. On this point the writer wishes to register a vigorous protest against the careless and misleading practice of designating as paraffins any hydrocarbon oil which is not dissolved by 98 per cent. sulphuric acid at room temperatures. Naphthenes, which are saturated ring compounds, are equally insoluble in sulphuric acid of this strength. Failure to take account of this fact has led to endless confusion in the interpretation of experimental results from the cracking of hydrocarbons. When we recognise the presence of naphthenes in petroleums (and the writer believes that naphthenes are present to a greater or less extent in the majority of crude oils), there is no mystery in obtaining benzene and other aromatic hydrocarbons by the cracking of petroleum distillates. Nor in the light of this is it difficult to see why one water gas tar should contain greater quantities of aromatic hydrocarbons than another tar made in the same machine under similar heats but with a different carburetting oil.



Specific Gravities of Non-Saturated Hydrocarbons

Fig. 3

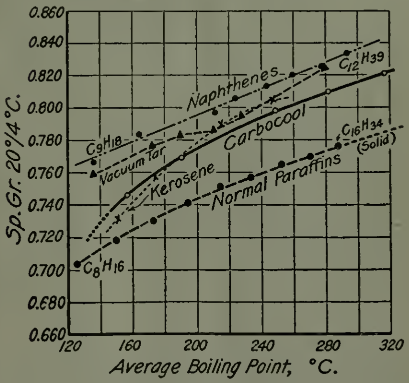
To sum up the work on carbocoal tar it has been shown that when the distillation of the tar is interrupted at a fixed temperature the pitch obtained has a much lower melting point and free carbon content than the pitch from high-temperature tars. If the distillation were carried on to give a pitch of the same melting point in each case, the percentage of pitch in the low-temperature tar will be considerably less.

The tar acids, constituting over 40 per cent. of the distillate of carbocoal tar, are mainly alkylated and hydrogenated derivatives of the familiar phenols of high-temperature tar. The nitrogen bases, about 2 per cent. of the distillate, are similarly related to the bases of high-temperature tar.

The neutral oils of carbocoal tar contain no aromatic compounds and only a small proportion of paraffins. The bulk of the neutral oils is made up of ring hydrocarbons with numerous side chains and more hydrogen in the ring than the aromatic hydrocarbons. If sufficient hydrogen is present to saturate the ring, these compounds are naphthenes, which are often carelessly confused with paraffins. If the amount of hydrogen in the ring is not sufficient to saturate, leaving one or more double bonds in the ring, the resulting compounds are unsaturated compounds of which di- and tetra-hydrobenzene are examples. This class of unsaturated cyclic hydrocarbons make up about 40 per cent. of the distillate of carbocoal tar.

Low-Temperature Tars from other Processes

In discussing other low-temperature tars we must recognise that first of all the nature of the tar depends upon the coal from which it is made. Low-temperature tar is tar as nearly in its primary form as it is possible to obtain under commercial conditions. Therefore it is more closely related to the coal substance itself than is any other form of tar. The low-temperature tars (*urteere*) of Germany, for instance, are made mainly from brown coal. They contain solid paraffins and are very different from the tar that has been described. In a similar way we would expect the low-temperature tar from our western (United States) lignites and from cannel coals[12] to be quite different.



Specific Gravities of Saturated Hydrocarbons

Fig. 4

The second point to be remembered in regard to the composition of low-temperature tars is that the vapours of primary tars, on account of the complexity of the compounds, are more sensitive to variations in temperature, pressure, gaseous atmosphere and contact surfaces than are the vapours of the simpler and more stable compounds of high-temperature tars. Hence differences in processes have a proportionally greater influence upon the composition of low-temperature tar than upon that of high-temperature tar. In this respect the main object of the process exerts a marked influence. In Germany the main object of low-temperature treatment is to obtain a substitute for petroleum. The processes have accordingly been regulated to give the highest yield of tar oils suitable for this purpose. It would be expected that even with the same fuel the low-temperature tar from German processes will vary considerably from the tar of English or American processes where the main object is to obtain either a suitable smokeless solid fuel or the best results in power gas. Again, we would expect the tar from a process designed to yield a smokeless fuel, such as the carbocoal, coalite or Parr-Layng process, to differ materially from the tar of a process working for complete gasification, such as the modified Mond or the Doherty processes. The MacLaurin process, whilst yielding a solid fuel, distils in the same way as the complete gasification processes and would be expected to give a similar tar.

---

[12] C. R. Fettke, *Trans. Amer. Inst. Min. Met. Eng.* (1923).

In general, if operating on the same fuel, we might expect the tar from the coalite process to be similar to the carbocoal tar. The tar from the Parr-Layng process might also be much the same as a carbocoal tar made from a high oxygen coal. The Parr-Layng process, however, would hardly be applicable to the coal used in making the tar which has been described.

The exact nature of the low-temperature tar from complete gasification processes is hard to predict. Since the heat for the distillation in the Doherty, Mond and MacLaurin processes is furnished entirely by hot gases which also give a vacuum distillation effect by diluting and sweeping out the tar vapours, and since the tar vapours are never exposed to a higher temperature than that at which they were formed, it is to be expected that the tars from these processes will be even more primary in nature than carbocoal tar. Also, since the gases bearing the tar vapours pass through fuel which is cooler than the fuel from which the tar was distilled, we would further expect that there might be a slight fractionating effect on the tar, which would free it from some of the higher boiling compounds and pitch. It is the hope of the writer that he may soon have the opportunity to test these predictions by examining the Doherty tar.

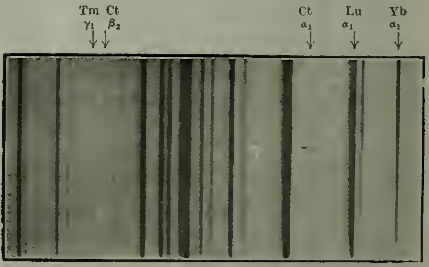
ON THE HIGH-FREQUENCY LINES OF CELTIUM

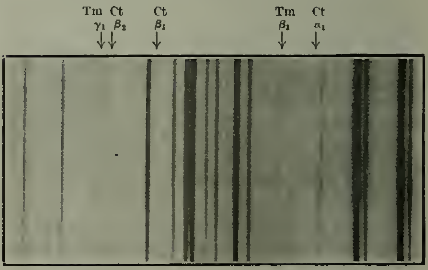
By A. DAUVILLIER

The value of X-ray analysis in proving the presence of a chemical element, even if it is only a trace, is due to the fact that merely one line, for instance, the ray $L\alpha_1$ is sufficient evidence. There is no line appearing on a photograph of such a spectrum whose origin cannot be identified. The problem is made easier because, if the proportion of the element is very small, there will only appear the line α_1, and generally one cannot distinguish more than four—α_1, β_1, β_2, γ_1.

The degree of precision in measuring a faint line, probably fairly diffuse in the case of the elements of the rare earths, has only a secondary importance if, in the spectral interval concerned, the lines of no other element appear.



No. 1



No. 2

The two photographic reproductions sent herewith have been taken directly from the original photographs. One can only just see in them the celtium lines, (No. 1) β_2, (No. 2) β_2 and α_1, but they show the general nature of the photographs obtained. The lines in question are clearly visible on the original plates to every reader, but have been very slightly strengthened to permit the accompanying illustration to be made. No 1 is the spectrum of the last fractionation of some ytterbium earths obtained by Prof. Urbain. The fraction contains twice as much lutecium as ytterbium and traces of thulium and celtium, the last two elements in equal quantity. No. 2 is an earlier fraction containing equal quantities of lutecium and ytterbium, the proportion of thulium is considerably larger, and that of celtium has not been altered.

It should be observed that the approximation obtained in our first determination for the lines β_2 and α_1 of celtium (nearly 4 units too little) is exactly the same as that obtained simultaneously for the strongest line β_2 of thulium (3·9 units too little, for γ_1 Tm 2 units too little), according to new measurements by Coster (*Phil. Mag.*, 46, Nov., 1923, p. 936). This difference well shows that this small error was due merely to the difficulty of "pointing" the lines correctly, as we had immediately perceived, for we referred to the probable values obtained by interpolation of Moseley's graph. The other possible attributions for the two lines of celtium have been discussed in previous notes. Mr. Coster finally suggests (*loc. cit.*) the possibilities: Pt Lα_2, Sr Kβ_1, and IKα_2, IKβ_1; but, besides the fact that these impurities are excluded chemically, the K lines could not be distinguished in the preceding orders and the stronger lines of platinum would have been distinguished before Lα_2 becomes visible. The other lines of celtium must be either too faint to be determined or masked by lines of lutecium and ytterbium. The photographs include, as will be seen, some 60 lines. They show the extreme intensity and dispersion which it is possible to obtain with a target of such oxides. The intensity of the lines of thulium aud celtium seems to correspond to a concentration of these elements of the order of a tenth of a thousand (10^{-4}), which is approximately the lowest limit which can be observed with the apparatus and method which we make use of.

In the case of metallic substances which are good conductors and refractory, like those of the platinum group, we have been able to reduce this limit to one-millionth, making use of a scale of intensity obtained by modifying the photographic factors. For an analysis which is at least qualitative there is no method more sensible or accurate than that of high-frequency spectra, by which each separate element appears precisely in proportion to its concentration. On the other hand, the sensibility of optical spectra depends very much on the chemical group concerned. Dr. Coster has searched for traces of celtium in a preparation of lutecium furnished by Auer von Welsbach, and has not observed any. Perhaps it never contained any, and there is no reason for such a content. But it is worthy of remark that our method has enabled us to show a very much larger number of lines in the L series than this author has observed. For instance, in the case of gold, Dr. Coster has only found 18 lines, whilst we have observed 36; in ytterbium he has found 14 against our 24, and for barium 20 against our 34. All our lines can be grouped in their proper series of optical types, in accordance with theory. This result is due to the fact that we have made better use of the anti-cathode material, that our dispersion is much greater and our efficiency much more greater, by reason of the use of homogeneous cathode rays. As to the presence of a trace of celtium, a tetravalent* element like *cerium*, in the last fractions of ytterbium earths, this is no cause for surprise if we consider how frequently tri-valent and tetra-valent elements are associated in nature. The detailed reasons justifying their occurrence have been the subject of a previous note. We need only mention that it is not exceptional, and that we have, on another occasion, observed the presence of a notable quantity of zirconium in a preparation of samarium, a pure trivalent element.

(*) We wish to point out that in all our previous papers we have always attributed 4 outer electrons to celtium and to cerium, as we considered them as higher homologues of zirconium.

PERSONALIA

Sir D. O. Masson, professor of chemistry in the University of Melbourne, has been elected the first president of the Australian Chemical Institute, which has now been incorporated.

Dr. Stephen Moulton Babcock, the originator of the Babcock test for milk, celebrated his eightieth year at his home in Madison, Wis., on October 22. Amongst work standing to Dr. Babcock's credit may be mentioned a viscosimeter, a gravimetric method for analysing milk, research on galactose, the digestive ferment in cheese and other problems relating to the treatment and utilisation of milk.

Professor Wyndham R. Dunstan, C.M.G., F.R.S., is resigning from the directorship of the Imperial Institute. He was professor of chemistry in the Pharmaceutical Society's School of Pharmacy from 1885 to 1896, a period during which he carried out, with Mr. F. H. Carr, researches on the alkaloids of aconite. Later he was appointed director of scientific and technical research at the Imperial Institute, finally succeeding Sir F. Abel as director of the Institute.

* * *

On December 1 the death occurred of Mr. S. K. Muspratt, formerly a member of the firm of Muspratt Brothers and Huntley, chemical manufacturers, and a nephew of the late Dr. E. K. Muspratt.

The net estate of the late Dr. E. K. Muspratt, of Seaforth Hall, Seaforth, Liverpool, President of the United Alkali Co., Ltd., amounted to £434,842.

With deep regret we announce the death of Mr. J. M. Wilkie last week after an operation. An obituary notice will be found on page 1189.

SOCIETY OF CHEMICAL INDUSTRY

LONDON SECTION

The preservation of building stone formed the subject of two papers at the meeting of the London Section on December 3. Dr. B. Dyer, Chairman of the Section, presided.

The first paper, by Mr. J. Allen Howe (Geological Survey of Great Britain), on "The Use and Preservation of Building Stone," was almost entirely of a geological nature, lantern slides being shown to illustrate the microstructure of various limestones and sandstones, and the manner in which these building stones are decaying on buildings in and near London.

In the second paper, Dr. J. J. Fox and Mr. T. W. Harrison gave an account of work done during recent years on the decay of building stone, especially in London, and particularly in relation to the question of bacterial action which has been revived recently. Apart from mechanical attrition the most potent decaying agent was water, not because it was water but because of the sulphur compounds it carried down from the air on to the stone. In the London atmosphere, the most destructive agent was the oxides of sulphur due to the coal fires. Experiments had been carried out to ascertain the amount of sulphur in the London atmosphere and also the amount of SO_2 in rain water, and it was concluded that sulphur dioxide and sulphur trioxide were the principal agents causing damage to building stone in London. Recently, the argument had been revived that decay of building stone is largely due to nitrifying bacteria, but the speaker's view was that this was not so in London and similar towns, and although this aspect might be important enough to demand investigation he did not think it could be regarded as of first importance. He did not believe that nitrifying organisms could resist the sulphur in the air.

None of the preservatives at present available for building stone were really effective. One school of thought said that the preservative should produce an impenetrable skin on the stone, whilst another alleged that this was wrong because it stopped the natural respiration of the stone. After examining many preservatives, he had come to the conclusion that all of them had objections. At the same time, it might be that they all did not have the objectionable features which were sometimes attributed to them and therefore it was time that large-scale experiments should be carried out to find out a suitable preservative. Such a series of large-scale experiments was recommended in 1861, but the proposal was turned down on the score of expense, the cost being estimated at £150. Practically all the preservatives now on the market were available in 1861, so that all this long time had been lost. The only thing to do now was to start such a series of experiments, not on a laboratory scale, but with a large piece of stone erected under ordinary conditions in the air. The results might not be available until the next generation but the experiment ought to be made.

The use of preservatives which alter the surface of the stone was objected to, for it would be just as well to use artificial stone, as this would last a considerable time if well made. Considering the use of organic or inorganic bodies for preservative purposes, he thought the most likely were inorganic colloids, although these had drawbacks. It had been advocated that a hard layer should be put on the surface of the stone, but as this layer would be of a different composition from that of the stone itself, it would not be a wise course to pursue.

Mr. Noel Heaton, who opened the discussion, commented on the fact that little, if any, progress has been made in the development of preservatives for building stone during the past 50 years and that many old preservatives, which have not been found suitable, kept turning up under new proprietary names. He agreed that too much stress had been laid upon the part played by nitrifying organisms in the decay of stone, and the arguments put forward to support such action were, to him, at any rate, absolutely unconvincing. The only way to deal with the whole problem was by exposure tests. Various laboratory methods had been suggested for testing preservatives for stone, but it seemed to him that these could never give a really reliable result. Several other speakers took part in the discussion. Mr. Walter Reid disagreed with the use of a preservative which put a film upon the stone; an account was given of some laboratory experiments by Mr. P. W. Blythe upon brick which, it was contended, indicated the possibility of arriving at a satisfactory laboratory method of dealing with the whole problem; and Mr. Howe in his reply emphasised the necessity for outside experiments upon stone in the form of actual pieces of building structures and exposed under the same conditions as buildings are.

BIRMINGHAM AND MIDLAND SECTION

The second meeting, held on November 27, in the University of Birmingham, was presided over by Dr. E. B. Maxted, and two papers were read.

The first paper, by Dr. D. F. Twiss and Messrs. F. Thomas and F. B. Jones, was entitled "Acceleration of Vulcanisation by Xanthates and the Influence of Metallic Oxides as Promoters." It was pointed out that in the presence of a zinc alkyl xanthate and zinc oxide, rubber can be vulcanised by sulphur rapidly at temperatures well below the boiling point of water. The zinc alkyl xanthate is the accelerating agent, but its effectiveness is greatly promoted by the presence of zinc oxide. The action is not catalytic. The zinc oxide acts as a "promoter" to many organic accelerators of vulcanisation. Cadmium oxide possesses similar power, but in a slightly less marked degree. The oxides of magnesium and mercury, metals of the same group of the Periodic Table, are themselves capable of accelerating vulcanisation, but have no appreciable activity as promoters. Remarkably little difference is detectable in the vulcanising power of soluble or insoluble sulphur respectively ($S\lambda$ and $S\mu$) between 88° C. and 188° C.

Dr. Twiss and Mr. F. B. Jones next gave a paper on "An Important Variable in Raw Rubber." Many physical characteristics have been made to act as a basis for testing the quality of rubber. A common method of examination is to vulcanise the material and measure the rate of vulcanisation or the mechanical features such as strength and extensibility of the vulcanised product. On vulcanisation with a generous proportion of sulphur, however, some samples of rubber attain a maximum tensile strength sharply after a certain period of heating, vulcanisation to a greater or a less degree resulting in a relatively great loss of strength; other samples, on the other hand, attain a high tensile strength over a relatively wide range of vulcanisation. Results were recorded in illustration of the variability in this direction. Indications were given of its importance and some factors were described which influence its development.

OFFICIAL NOTICES

ROTHAMSTED LIBRARY

By the courtesy of the Lawes Agricultural Trust, any member of the Society of Chemical Industry on presenting a card from the General Secretary shall be allowed access to this Library. The rules of the Library preclude journals and periodicals from being sent out, and these are therefore always accessible.

A catalogue of the journals and periodicals is in the Society's Offices, at Central House, and may be consulted there by members.

CHEMICAL SOCIETY'S LIBRARY

Members are reminded that, in accordance with arrangements entered into by the Council, they are now entitled to consult the Library of the Chemical Society, Burlington House, Piccadilly, W. 1, and to borrow books therefrom.

The Library is open daily from 10 a.m. to 9 p.m.; Saturdays, from 10 a.m. to 5 p.m. As hitherto, the Library will be closed on Bank Holidays, the day following, and on other such occasions as the Council may direct.

SOCIETY OF GLASS TECHNOLOGY

Three papers were read at the meeting held in Leeds on November 21, the President, Prof. W. E. S. Turner, D.Sc., in the chair. In the first paper, entitled "Notes on the Influence of Rapid Chilling on the Reversible Expansion of Clay," by H. S. Houldsworth, M.Sc., some results were given of measuring the reversible thermal expansion of fireclay test pieces cooled slowly and rapidly. Test pieces were moulded from Farnley fireclay, dried, fired to Cone 9 (1280° C.) in three hours, and maintained at that temperature for a further 2 hours. One test piece was plunged into cold water, another was left to air cool, and a third was allowed to cool slowly in the furnace for 17 hours. All the results were consistent with the explanation that solution of free silica occurred at the higher temperature of heating, that this separated out as cristobalite or tridymite on slow cooling, and exerted its characteristic influence on the expansion curve, but that it did not so separate on rapid cooling. Some imperfect separation was, perhaps, likely, but not in a sufficiently definite form as to be able to exert its proper influence on expansion.

A paper by P. Marson on "Glasshouse Pots: Some Notes on their Manufacture and Use," was read by Prof. W. E. S. Turner in the absence of the author. The grog used in pot-clay mixtures should not be burnt to less than 1350° C., and should be free from the faults of burning, such as black core and soft firing. The grading should also be kept within prescribed standards, viz., not coarser than 10 mesh for pot-clay grog, giving a residue of not more than 35 per cent. on a 16 mesh screen, and for the blend a mixture of 25 per cent. grog to 75 per cent. clay was the most suitable for general purposes. The dry clay, if satisfactory, was allowed to sour in water for a month, then trodden ready for use. Pots stored for two or three years after drying gave better results than new ones. and at least nine days should be occupied in heating up in the pot arch. After transferring the pot to the furnace, it should be left to mature for forty-eight hours before opening or filling on. Various faults developed by pots during manufacture and use were also discussed.

Prof. Kurd Endell, of the Technical *Hochschule*, Berlin, read a paper on "The Casting Process for Glasshouse Refractories in German Glass Plants." Prof. Endell considered that the casting process would give satisfactory results in practice. Success depended upon careful and trained supervision, as well as on the proper selection and preliminary treatment of the clay. When the articles were required for internal use, or when only certain standard sizes of pots or blocks were to be made, manufacture by casting was undoubtedly more economical than by hand. All tests hitherto made showed that cast pots were denser than hand-made ones, and he believed that cast pots were chemically more resistant to molten glass than hand-made pots. Tests both with Seger cones and under load showed no perceptible difference in heat resistance between cast pots and hand-made pots. He confidently anticipated that the use of the casting process for the shaping of refractory materials would gain an increasing number of adherents.

ROYAL MICROSCOPICAL SOCIETY

At a meeting held on November 21, Prof. F. J. Cheshire in the chair, Mr. F. I. G. Rawlins read a paper on "The Microscope in Physics."

Mr. Rawlins first considered the technique of conoscopic methods in microscopy as used for examining the effect of crystalline plates upon convergent polarised light. It was emphasised that surface structure had nothing to do with the phenomena observed—"interference figures," or the plane sections of a family of "isochromatic surfaces." In quantitative work monochromatic light was essential, though Wratten filters (especially Naphthol green) could be used to a limited extent. Suggestions were made for improvements in microscopes for use in the physical laboratory.

SOCIETY OF DYERS AND COLOURISTS

Mr. W. Marshall, presided over the meeting of the Manchester section on November 16, when a paper entitled, "Investigation into the Changes which occur in Cotton Fabrics during Calendering and Beetling," by J. Huebner, M.Sc., and V. Malwin, M.Sc., was read by Mr. Huebner.

The authors have investigated the changes which occur in cotton fabrics during calendering and beetling, and have found that hot calendering results in an increase in the ripping strain of the fabrics, whilst the tensile strain decreases. Hot calendering on one of the fabrics, after impregnation with a 10 per cent. starch paste, produced similar results as regards the tensile strain, but the increase in the ripping strain was less and more regular in the starched than in the unstarched fabric. Another starched fabric, however, showed an increase in both the ripping and the tensile strain after calendering. Cold calendering also increases the ripping strain, but it does not affect the tensile strain. Beetling is responsible for a very considerable increase in the ripping strain, whereas the tensile strain remains practically unchanged. Embossing of both unstarched and starched fabrics increases the ripping strain, but the decrease in the tensile strain of the unstarched fabric is greater than that which results from ordinary hot calendering. The tensile strain of the starched fabric, however, is less affected than that of the unstarched fabric. Immersion of both the calendered and beetled fabric in a weak solution of iodine in potassium iodide and water showed that the amount of iodine absorbed by the fabric increased gradually with prolonged calendering and beetling. The colouration of the fabric produced by the iodine also became darker after prolonged calendering and beetling. When fabrics which had been immersed in the iodine solution were exposed to the air, it was found that whilst the untreated fabric was of a light bluish tinge, the heavily calendered and beetled fabrics were tinted a pale blue. After prolonged exposure to the air the blue colouration disappeared from all the fabrics, but the fading proceeded less rapidly the longer the fabric had been calendered or beetled.

HULL CHEMICAL AND ENGINEERING SOCIETY

A paper on "Recent Advances in Colloid Chemistry" was read by Mr. A. V. Slater at the meeting held on November 27, with Mr. H. A. Scruton, B.Sc., in the chair. After a brief introduction showing the importance of colloid chemistry in industry, the author reviewed recent theoretical advances. The nature of surfaces considered in the light of the researches of Hardy, Langmuir and Harkins, was governed by (1) orientation of molecules and (2) residual valency, which could explain many of the anomalies of surface tension and interfacial phenomena, and therefore of colloidal behaviour. Sir W. Bragg considered that the colloid was built up in the same way as the crystal and only differed because the surface molecules had not slipped into their proper places, and this was further borne out by von Weimarn's work which indicated that the environment of the separating phase determined its crystalline or colloidal condition. The evidence brought forward by Hardy, McBain, Pauli and Loeb for the existence of an ionic micelle or colloidal electrolyte as the colloid unit was briefly presented, and the lecturer expressed his own view that the theory of colloids could be explained satisfactorily neither by the purely chemical nor by the physical adsorption concept. but that a correlation of the two by the light of recent research on surfaces and interfaces was necessary. The most recent industrial developments of colloid chemistry were reviewed and illustrated by charts and experiments.

ACADÉMIE DES SCIENCES

On October 29 a commemorative discourse on Maurice Le Blanc was delivered by Monsieur Haller, who said: "Inventor above all, Maurice Le Blanc brought to industry a wide and at the same time deep knowledge allied to a powerful creative imagination. His work on alternating current motors, on the theory of induction motors, and similar subjects places him on the first rank amongst modern electricians." He also did work on pumps and turbines, and constructed a refrigerating machine based on a novel principle. He will be remembered also for his work on the steam engine condenser.

An oration was pronounced on November 5 by Monsieur Haller in memory of Count Arnaut de Gramont, an academician who died on October 31. Monsieur Haller described de Gramont's work on spectroscopy, particularly on the dissociation spectra produced by the discharge from an electrostatic condenser sparking at the surface of a compound, and in which all the elements constituting the compound gave independently their particular spectra and lines. To him are also due numerous researches on the spark spectra of liquids, and on the use of the oxy-acetylene flame in spectroscopy.

A new theory of chlorophyll was described by M. Maquenne, based on a colloidal conception, and in opposition to the classic hypothesis of Baeyer. Monsieur Haller read a paper by Monsieur Zelenski, in which the author stated that from 1000 g. of tar he had obtained 350 g. of benzene, and a certain quantity of higher homologues, utilising the reaction discovered by Berthelot, for synthesising benzene from acetylene. In this process the acetylene passes over activated carbon and gives yields which hold out hopes of an industrial future for the method.

During the meeting held on November 12, the perpetual secretary, Monsieur Picard, communicated a note by Prof. Lorenz pointing out that in 1858 Solvay discussed the question of the variation of mass in chemical reactions, a variation which constitutes the chief objection that can be raised to-day against the classic law of Lavoisier. Lavoisier had attempted to ascertain experimentally this variation of mass both in chemical and physical reactions, but obtained no results. Lorenz therefore observes that this variation of mass expressed by the ratio of the variation of the energy to the square of the speed to its propagation, *i.e.*, the square of 300,000 km. per second, is necessarily an infinitesimally small quantity.

Monsieur G. Bertrand described a method of covering organic bodies with metal, due to Monsieur Zélinski, professor of chemistry of the University of Moscow. On heating, for example, an insect covered with powdered copper oxide in a current of carbon dioxide, it will be found after cooling to have undergone no change in shape, but to be completely metallised and, as it were, covered with copper. This phenomenon was explained by the formation of very unstable gaseous copper carbonyl which was quickly decomposed. The formation of this new gas makes it possible to explain and avoid certain errors common in the detection of copper in food materials. Monsieur Le Chatelier observed that he had obtained similar results.

Monsieur Breton communicated a paper by MM. Chevalier and Dantony, recommending the use of stalks and leaves of pyrethrum instead of the expensive leaves for the preparation of insecticides. A method of estimating lævulosans in cereal grains was described by Monsieur Lindet, and Monsieur L. Guillet read a paper on the electrical resistance of commercial aluminium.

On November 19 a note was presented by Monsieur Vinogradsky, describing a method enabling microbial action to be studied by direct microscopical observation in soil in which various chemicals had been incorporated. A note by MM. Lesiné, de Gennes and Guillaumin was communicated, dealing with the variations in blood phosphorus in patients suffering from rickets, and exposed to ultra-violet rays.

THE INSTITUTION OF THE RUBBER INDUSTRY

At the meeting held in London on December 3, 1923, at the Engineers' Club, a paper on "Rubber Accelerators" was read by Major V. Lefebure.

The speaker observed that there seemed to be a good deal of misunderstanding in the British rubber industry as to the position and value of rubber accelerators in general rubber practice. The bulk manufacture and use of rubber accelerators in all countries at present, and the enormous tonnage of rubber mix committed to the care of accelerators, permitted no doubt on this point. The question, rather, was the choice and proper use of the correct accelerator for a particular purpose. The simple facts that the world's consumption of organic accelerators was certainly more than 3000 tons per annum, and that reputable products varying from tyres to hard rubber had been based on accelerated cures for a number of years, meant that the industry which was backward in accelerator practice was ignoring one of the chief factors in successful competitive production. Accelerator practice had suffered in all countries, particularly in England, from the sale and use of unstandardised and disguised specialities, which admitted no intelligent control and certain standard output. Accelerators could be graded according to their relative speed in typical mixes, and it could be said that with proper use they had no harmful influence on milling, storage and ageing. England had been backward in the development of organic accelerators. Just as we failed to hold the great advantages which were once ours in the dye industry, so we had allowed other countries, in particular America, to forge ahead in a field in which, through the work of Peachey and others, we once held a dominating position.

CORRESPONDENCE

SILICA GEL

SIR,—My attention has been drawn to the letter by Dr. Chaney in *Chemistry and Industry* of November 23. I do not intend to begin a controversy on Silica Gel *v.* Activated Carbon, but exception must be taken to that part of his letter where, writing of silica gel and benzol, he says :—" A prerequisite of its employment is a careful drying of the gases." Either Dr. Chaney has misused the word " prerequisite " or he has no real knowledge of silica gel.

Silica gel is in use as a commercial proposition for the recovery and refining of benzol from coke-oven gases, and the gas enters the gel plant in exactly the same condition as it would enter the oil washers.

The fact that activated carbons have been more or less in use for so many years without making any substantial progress, while silica gel has in so short a time made such enormous strides, shows that it has passed what Mr. Rex Furness calls the final test—*i.e.*, the balance-sheet.—I am, Sir, etc.,

London, S.W. 1 J. ARTHUR REAVELL
December 3, 1923

BRITISH DYESTUFFS INDUSTRY

SIR,—In reply to the letter from Mr. C. M. Whittaker, published in your issue of 16th inst., we wish to correct the erroneous impression created by Mr. Whittaker in his earlier letter, that the price of British-made Direct Sky Blue, was, on the date he mentioned, twelve times the pre-war price.

As a matter of actual fact, the quality of Sky Blue made by this company is quite equal, in all respects, to the pre-war German types of Diamine Sky Blue FF., and Chicago Blue 6B., and the price was, and is, less than half the figure mentioned by your correspondent.—We are, Sir, etc.,

The Clayton Aniline Co., Ltd.
Manchester
November 28, 1923

THE CARRIAGE OF DANGEROUS GOODS

SIR,—From time to time the non-technical journalist supplies, in all good faith, misleading information, and I fear that it is seldom possible to catch up with items of news which are widely circulated and which contain statements of dubious accuracy.

A paragraph recently circulated and quoted by the Technical Press refers to a violent explosion which set fire to and sank the British steamer " Otterburn." The paragraph concludes by saying that the disaster was thought to be due to the explosion of barrels of chlorate of potash. I am informed, on what appears to be quite good authority, that there was no chlorate of potash on board the ship, but that there was a parcel of chloride of potassium.

The transport of dangerous substances is always a matter of difficulty, and it is therefore desirable that one should not unwittingly increase the difficulties by blaming a dangerous substance unnecessarily. To weigh down the statistics of explosions due to chlorate of potash by such items of news as that to which I refer would be misleading, and prejudicial to those firms who have to send abroad such goods—I am, Sir, etc.,

W. J. U. WOOLCOCK,
General Manager
Association of British Chemical Manufacturers,
166, Piccadilly, W.1

OBITUARY

J. M. WILKIE

John Matthew Wilkie was born at Montrose in 1876, and was educated as a pharmaceutical chemist. After passing his minor in Edinburgh he came to Derby as assistant to Mr. Frost, a high-class pharmacist of the old school. Later he went to London, and in 1900 was appointed as an assistant analyst in the laboratory of Boots Pure Drug Co., where he remained till his death. For many years past he was the deputy chief analyst, and was largely responsible for the work of the laboratory. By indomitable energy and by studying after a hard day's work he took the B.Sc. degree of the London University and the Associateship of the Institute of Chemistry by examination, taking the Fellowship in due course. Mr. Wilkie was always a keen investigator and numerous methods are known by his name. Perhaps the best known of his researches are the paper on the estimation of small quantities of lead, published with Mr. Harvey, the silver methods for the determination of phosphoric acid and the alkaline iodine oxidation of phenols, the two last researches being published in the *Journal* of the Society of Chemical Industry. He also devised a most ingenious method for the estimation of sulphur and oxidised sulphur compounds, which depended on the formation of acid by the bromine oxidation, but this research has only been published in abstract, as he was never quite satisfied that he had brought it to a satisfactory completion, and he shrank from publishing results which did not prove his point up to the hilt. These sulphur oxidation methods have, however, been in use at Boots' laboratory for some years with most satisfactory results. The last four years of his life was devoted to an almost monumental research on the determination of minimal quantities of arsenic. At the time of his death the work was concluded, and he was engaged in putting his notes into order for publication. This research was given to the world in abstract at the highly successful joint meeting of the Society of Public Analysts with the Nottingham Section of the Society of Chemical Industry. Wilkie was always a keen supporter of the Society, and as secretary to the Nottingham Section from 1914 to the present year he was largely responsible for the success of that Section and the great increase in the membership. He put his heart and soul into it, and it is safe to say that without him the interesting programmes of meetings, many of them joint meetings with other societies, would not have been held. He had just relinquished the secretaryship and had become chairman, and although he had only presided at one meeting he signalised that by inaugurating a discussion in which a large number of young members were persuaded to take part. It was always Wilkie's policy to encourage and bring forward the young talent, so much so that at Mrs. Wilkie's special request he was borne to his last resting-place by the young men that he used to encourage and talk about so often.

He was a highly informed man and talked English with great purity; highly conscientious, a hard worker, he persuaded others to work by his enthusiasm, and his colleagues all mourn him as a true and trusty friend. An accident in early youth partially deprived him of the use of the right arm, but nevertheless he was in his youth a keen football player and later in life an enthusiastic golfer. He died on November 29, after an operation.

NEWS AND NOTES

FRANCE

Petroleum

The proposal to establish an "office national du pétrole" has obtained a mixed reception. To meet the objection against State participation in the industry, it is proposed to establish a separate financial organisation with the help of companies and banks interested in the petroleum industry. Discussion between the Government and interested parties is now going on with a view to the formation of this organisation.

A natural-gas well, yielding an average of about 60,000 cb. m. a day, was discovered at Vaux en Birgey (Ain) in 1922. The gas contains 91–92 per cent. of combustible gas, 2–3 per cent. of carbon dioxide, and 4–5 per cent. of nitrogen, the heating value being 8600–9600 calories. The gas is now being supplied to the town of Ambérien, and it is also being stored under pressure in cylinders.

Metallurgy

Tests are being made at the Conservatoire National des Arts et Métiers at Paris of steel tempered after treatment in a new electric furnace devised by Messrs. Wild and Barfield, two English engineers. In this furnace, the moment when the steel reaches its transformation point is recorded automatically, and it can then be removed and tempered. The method is based on the fact that when steel reaches its transformation point it is no longer magnetic, and this is recorded, by means of suitable electrical wiring, by a galvanometer. The energy consumed by the furnace is 4·2 kw. per hour.

Beet Sugar

It is estimated that during the 1923–24 season, 95 beet-sugar factories will be operated in France, and that the production will be 480,000 metric tons of sugar, compared with a yearly consumption amounting to 700,000—800,000 t. In 1923 the area cultivated was 150,000 hectares, and the output of sugar in 90 factories was 445,000 t. In 1913–14 there were 209 factories, with a total production of 785,550 t. from 229,000 hectares, and the consumption was 710,000 t.

The "Quinzaine du Bois"

A number of interesting addresses were delivered during the fortnight devoted to the discussion of problems relating to wood during October in Lyons. Prof. Brot discussed the manufacture of cellulose pulp in France, and stated that the French production was 80,000 metric tons annually, whereas imports amounted to 2,100,000 t. The timber resources of Tunisia were described by M. Barriocilet, and Mr. Guinier dealt with French timber reserves, which cover over 10 million hectares, yielding 8·5 million cb. m. of timber and 17 million cb. m. of firewood per annum. The utilisation of the Landes pine for the production of cellulose for making paper and gunpowder was discussed by M. M. Jaffard. Such cellulose, obtained by the alkali and chlorination processes, was quite comparable to Kraft pulp, and could be used for making viscose and cellulose esters. Further, the yield (based on the wood) of 6 to 8 per cent. of resin suggested use for making resin soaps, dressing paper, etc.

UNITED STATES

Nomenclature of Petroleum Products

The joint committee of the American Society for Testing Materials and the American Petroleum Institute, established to consider the nomenclature of petroleum and its products, has issued a report containing the following definitions of the terms "crude petroleum," "weathered crude," "benzine," "petroleum naphtha," "gasoline," and "petroleum spirits."

Crude petroleum (crude oil, petroleum, crude). —A naturally occurring mixture, consisting predominantly of hydrocarbons, which is removed from the earth in liquid state, or is capable of being so removed.

Weathered crude.—A crude petroleum from which a perceptible quantity of the more volatile constituents has evaporated.

Benzine.—This term is archaic and misleading and should not be used.

Petroleum naphtha.—A generic term applied to refined or unrefined petroleum products and liquid products of natural gas, at least 95 per cent. of which distil below 500° F. when distilled in accordance with the tentative method of test for distillation of gasoline, naphtha, kerosene and similar petroleum products (serial designations: D 86–23 T of the American Society for Testing Materials).

Gasoline.—A refined petroleum naphtha which by its composition is suited as a carburant for internal-combustion engines.

Petroleum spirits. — A refined petroleum naphtha, with a minimum flash point of 70° F. (tag closed tester A.S.T.M. standard), with a volatility and other properties making it suitable as a thinner and solvent in paints, varnishes and similar products.—(*Chem. and Met. Eng., Sept.* 3, 1923.)

JAPAN

The Agar-agar Industry

During the period 1911-1920 the average annual output of agar-agar in Japan was approximately 3 million ℔. For the 1922-23 season the output was estimated at 2,400,000 ℔., but owing to unfavourable weather conditions in February, 1923, considerable quantities were discoloured and had to be sold as third grade. Agar-agar is usually marketed in three grades, the chemical composition of which is the same, the difference in quality being due to colour. It is also produced as shredded or "hoso kanten," or in the block form called "kaku kanten." About 75 per cent. of the output is exported, China and the Malay States taking 60 per cent. of the export, the remainder going to the United States, Great Britain, France and Germany. Shipments to Europe and America during 1923 have so far been very large, amounting to 1,600,000 ℔.—(*U.S. Comm. Rep., Sept.* 17, 1923.)

GENERAL

Projected Entente among Indigo Producers

It is believed that the recent agreement between American, British and Swiss indigo producers will develop into a chemical entente in order to meet the "economic accord" which is said to be projected by the French and German industry, and which may possibly be extended to Italy and Czechoslovakia. This arrangement will have the great advantage that it will enable research and development work to be co-ordinated. The value of association, if not the necessity of it, has been proved by the German cartel which was organised in 1916 and then extended in 1919 to 1999. The possibility that distribution may be allocated is foreshadowed, and it is stated that the chemical and allied industries in the United States, Switzerland and Great Britain are admirably adapted for association.—(*Chem. & Met. Eng., Oct.* 29, 1923.)

REVIEWS

Thermodynamics and the Free Energy of Chemical Substances. *By* Prof. G. N. Lewis *and* M. Randall. *Pp. xxiii*+653. *London: McGraw-Hill Publishing Co., Ltd.*, 1923. *Price* 25*s*.

This is a book on the application of thermodynamics to chemical problems. According to the authors it "is not a text book in the ordinary sense of the term." What authors generally mean when they say this is that most text books are bad, and theirs is good; and in this case there is some justification for the natural pride of the authors. Apart from this, the authors' statement is true in a sense which is not precisely what they intend to convey. An ordinary text-book would be expected to give due attention to all the important original work published on the subject; but the book under review, so far as recent developments of thermodynamics are concerned, consists largely of an exposition of the original work of Lewis and his colleagues and pays comparatively little attention to the work of other investigators. Particularly is this true of German work; Haber receives a few kind references, and a somewhat grudging bouquet is presented to Nernst in the opening chapter; but the work of the latter hardly receives the attention it deserves. Apart from this defect—and it is a defect—there can be little doubt of the value of the book. It is the product of the thought of years and nearly every page of it bears witness to the great care bestowed on it by the authors. It deserves, and will get, the closest attention of all serious students of the subject.

A most important feature of the book is the attention which is paid to the conception of the free energy of chemical reactions. There is often some confusion in other books in the treatment of free energy, but Lewis and Randall attack the subject boldly and successfully. In their discussion of the applications of the third law, they show, by the analysis of a large amount of experimental data, how the free energies of formation of chemical compounds from their elements can be calculated, and how from the figures so obtained, the state of equilibrium in any conceivable chemical reaction between these compounds can be calculated under different conditions. This system suffers from a defect which is unavoidable in the present state of knowledge of the specific heats of gases and liquids. The calculations of the free energies of formation of compounds can only be approximate at the best; hence, if the change in the free energy in any given chemical reaction is small, calculation of the state of equilibrium at any temperature must inevitably be very uncertain. On the other hand, if the change in free energy is large, calculations on Lewis' system will give results of the right order of magnitude. In this respect it seems to the reviewer, that the system expounded in this book is open to objections similar to those which the authors apply to Nernst's system of 'empirical chemical constants,' of which they remark that "the various efforts which have been made to square the calculations based on these constants with the results of equilibrium measurements constitute a regrettable episode in the history of chemistry."

The phraseology employed by the authors occasionally pulls the reader up with a jerk. Is there any real necessity for such elaborations as "partial molal free energy," "limiting molal lowering (of freezing point) "molality," etc ? As for the notation, the authors claim that their system has been tried out thoroughly for many years and has proved satisfactory. This may be so—and certainly once one gets used to the system, there is no ambiguity as to what the authors mean by their notation—but it is a real handicap to a student to find different authors using different conventions, and it does seem that the time has come when there should be some international agreement in this matter.

The book is well printed and produced, and has the merit of possessing a good index. It is a credit to the publishers as well as to the authors.

H. T. TIZARD

1. THE PROPERTIES OF MATTER. *By* BASIL C. MCEWEN, M.C., B.Sc. *Pp. vii*+316. *London: Longmans, Green and Co.* 1923. *Price* 10*s*. 6*d*. *net*.
2. MATERIE, ELEKTRIZITÄT, ENERGIE: DIE ENTWICKLUNG DER ATOMISTIK IN DEN LETZTEN ZEHN JAHREN. *By* WALTHER GERLACH. (*Wissenschaftliche Forschungsberichte. Volume VII.*) *Pp. viii*+195. *Dresden and Leipzig; Theodor Steinkopff,* 1923. *Price* 3*s*. 3*d*.

(1) Mr. McEwen's book follows the usual lines, except that he begins with gases and ends with solids (which seems to be an improvement on the usual order), and includes more Heat than is generally the case. The treatment is clear, and the mathematics simple. The descriptions of experiments are good, and the book is one which students for the Pass B.Sc. will find useful. The symbols are often unusual, *e.g.*, C_v for c'_v, Cm_v for C_v. No mention is made in the long discussion of specific heats of gases that these vary with temperature, and recent work is ignored. The discussion of critical solution temperatures along with the critical temperatures of liquids is confusing. There should have been a fuller discussion of the recent work on the determination of Avogadro's constant—in fact, the neglect of work done during the last ten or twenty years is the outstanding weakness of the book.

(2) Prof. Gerlach's book deals with some branches of the study of atoms, electrons and radiation which have been prominent during the last decade. In pleasing contrast with other works of this type the attention of the reader is invited to a diversity of experimental investigations, and the theoretical discussion is kept within moderate limits. The treatment, although quantitative, is generally non-mathematical, only the necessary formulæ (mostly simple) being introduced. After the discussion of atomic structure, isotopes and the electronic charge, there are interesting sections on matters such as the "super-conducting" state of metals, the radiometer effect, visible, infra-red and X-ray spectra (on the basis of Bohr's theory), photochemistry, etc. There are many literature references but no index. The book is one which all chemists should find interesting and intelligible.

J. R. PARTINGTON

SYNTHETIC INORGANIC CHEMISTRY: A COURSE OF LABORATORY AND CLASSROOM STUDY FOR FIRST YEAR COLLEGE STUDENTS. *By* ARTHUR A. BLANCHARD AND JOSEPH W. PHELAN. *Third edition: entirely rewritten and greatly enlarged. Pp. xiv*+321. *New York: John Wiley and Sons, Inc.*, 1922 *Price* 15*s*.

An authentic student's book of chemistry from so important a centre as the Massachusetts Institute of Technology (known familiarly by the intolerable contraction, "the Boston Tech.") must be of great interest to teachers on both sides of the Atlantic, and the one before us, which might, perhaps, as well have been called by the more familiar title of "Inorganic Preparations," is, indeed, worthy of very close examination. It is, of course, not a book to read in an arm-chair or at a desk, and it is unlikely that any honest reviewer could say that he had read it from cover to cover.

The chief thing a teacher or an ex-teacher looks for in such a work is new light—in beams, rather than in single rays. Does this new book show any broadly better ways of performing the old tasks ? If so, let us commend them to the world. The answer to this may, I think, be fairly said to be "in the negative," but I hasten to add that with still greater definiteness, but this time in the affirmative, would come the answer to a second question: does this book do the old work better than usual ? There is, indeed, evidence throughout of very great care, well collated experience, and an abundance of little novel things which collectively make the whole a pleasure to read and to commend to laboratory teachers.

It should be pointed out that the book is by no means limited to prescriptions, nor yet to rational teaching linked to isolated experiments. There is evidence, throughout, of a lure, which the authors acknowledge, towards a general expository treatment of inorganic chemistry as a whole, and, indeed, there are large stretches where the authors have as it were broken loose from the laboratory bench in their most forgivable ardour as chemical philosophers.

One may hope for large new ideas in the teaching of inorganic chemistry, but, perhaps, hardly expect them. In the details of methods and manipulation, the expectation of something new is more justifiable, and from America, which in so high a degree has been the country of invention (I confess to be thinking of mincing machines, sweepers, and perfect tea-pots). one has hoped particularly for improvements of the kind referred to. Whilst in the book before us there are here and there little modifications, it is not easy to find anything strikingly new which can be quoted. The thing which has stuck most in my mind whilst examining the book has been "the paper towel"—to me an unknown adjunct. It appears to be paper with the absorptive power of filter paper and the tenacity of parchment, but I am not sure. If the paper towels are really effective for wiping glass and for drying crystals; if they can be made at such a price that you can compel every student to have a new one as frequently as the member of a first-class club has a clean one of the older sort, they will contribute an ingredient to the practice of laboratory chemistry that is perhaps more usually lacking than any other.

As one believing most strongly not only in the virtue, but in the necessity of an extended training, of every chemical student whatsoever. in what our authors call synthetic inorganic chemistry, I gladly recommend the work under review. not, as already stated, that there is in it a great deal that is very new, but because it is a book written by earnest men which will certainly give to the watchful teacher a good yield of useful hints.

On the other side of the account one may, of course, point out what appear to be deficiencies, but these, where they exist, are mostly of detail and may best be noted direct to the authors. In a general way one may, and perhaps, must complain of the absence of an index, and on the slight tendency, apt to appear in American works, to what may be gently called a kind of pedantry. Why, for example, drag in "metathesis"? Who ever uses such a term in civilised life? Why say "molal" rather than "molar"? And what in the world is the man in the chemist's shop to understand by "a formal solution"? Such language is positively dangerous. On major questions I venture the opinion that under pre-war Teutonic influence American chemistry tended to "over-ionisation" and that there are still signs of it—I mean an overstrained use of that Ostwaldism which pushed Arrhenius into places far too narrow for his own or other people's comfort.

Arthur Smithells

L'Industrie du Gaz: Distillation de la Houille. *By* R. Masse and A. Baril. *Encyclopédie Léauté. Pp. vii*+292. *Paris*: *Gauthier-Villars et Cie.*, 1923. *Price* 20 *francs*.

L'Industrie du Gaz: Traitement des Produits et Sous-Produits. *By* René Masse and Auguste Baril. *Pp. xvii*+308. *Paris*: *Masson et Cie*, 1923. *Price* 20 *francs*.

The Gas Industry is one of the most important industries of this country, dealing, as it does, with a considerable proportion of our chief natural asset, coal. Not only is the industry itself a vast one, but it provides necessary raw materials for many other industries of prime importance. One of the most striking features of the industry is the wide scope of its operations, and those who read the works under review will be impressed with the skill which has enabled the authors to cover so wide a field in two comparatively small volumes.

The two volumes form part of a series of works (Encyclopédie Léauté) on technical subjects, and serve more by way of a general treatise than a specialised study of the diverse processes carried on. This is not to say that the specialist will not find information of service, as in a number of instances very worthy processes and plants are described to which it would be difficult to find reference in our own language.

The volume "Distillation de la Houille" deals with the process and plant required for carbonising coal and gasifying coal and coke. A short historical introduction repeats the erroneous derivation of the word "gas" from the Dutch "geest"* and gives undue prominence to the experiments of Lebon (1767) in carbonising sawdust. There appear to have been many men in many countries who disdiscovered gas, but no one prior to Murdoch had the audacity to expose himself in its light to the public view.

The consideration given to various types of coal appears inadequate and not in proportion to the excellent treatment given to the generation of heat and application of heat to carbonisation purposes. Thermal and carbon balance sheets are very appropriately inserted. Here and there is evidence that the authors are a little behind the times. The scale of Seger cone temperature indications is now out of date, whilst the Wanner pyrometer is now provided with two scales, one reading from 650–1130° C. and one from 840–2000° C. An improved instrument of similar type is made in this country.

The treatment accorded to the subject of refractory materials is disappointing, and one would imagine that the authors can hardly have been aware of the great improvement in quality and extension in use which silica materials have received in the last few years.

---

* See *Chemistry and Industry*, 1923, 325, 349.

Different types of carbonising plant, including the coke oven, are described; and the design and function of many of the devices used are made particularly clear. Details of labour required for operation of plant is a noteworthy feature.

In the second volume the cooling of the gas, the extraction of tar, various types of exhausters, pressure-regulating governors, gas washers, and purification processes are dealt with in a useful manner. Theoretical calculations are introduced in quite a digestible form.

The measurement, storage and delivery of the gas from station holders are followed by a very brief chapter on the composition and physical properties of coal gas. The distribution of gas occupies some 21 pages, and brings the reader to the sections dealing with byproducts.

The recovery and manufacture of benzol products occupies a prominent place, and some attention is given to the too often neglected subject of the quality and condition of coke.

The working up of ammoniacal liquor with production of ammonium sulphate and concentrated pure ammonia solutions are briefly described, but it is surprising that no mention is made of the great attention recently given—in this country at all events—to improvement in the physical condition and neutrality of sulphate of ammonia.

Methods of treatment of coal tar are well described and short accounts given of the purification of the component liquids and solids.

Finally, the plan and position of the sites of gasworks are discussed. A copy of the model clauses of the "Concession" given to French gas undertakings is appended.

The most serious criticism that one can offer is that in a number of instances the matter is not quite up-to-date, notably in the theory of carbonisation, the subject of refractory materials, and the use of recording instruments. It would have rendered the work far more useful if in all instances references to literature had been added in footnotes, following a name which is mentioned in the text.

The printing is good and the illustrations are very clear, but in one or two cases on a very small scale. The paper is of poor quality. There is one advantage in the paper back, and that is that, in spite of the ingenious argument of the editor, one may remove the miscellaneous advertisements from the end of each volume before re-binding the books for one's bookshelf.

As a general descriptive work, concise and complete, the volumes can certainly be recommended.

GEOFFREY WEYMAN

REPORTS

REPORT ON THE ECONOMIC AND INDUSTRIAL CONDITIONS IN ESTHONIA. DATED JUNE, 1923. *By* J. E. P. LESLIE, *H.M. Consul, Reval, and* W. J. SULLIVAN, *Vice-Consul, Reval. Department of Overseas Trade. Pp.* 28. *London: H.M. Stationery Office.* 1923. *Price* 1*s.*

The economic and political conditions of this new country are strongly bound up, since financial developments are largely dependent on political events. The handling of the Communist element, which has been firm, and the avoidance of currency inflation show, however, that popular opinion is averse to extreme measures.

Agricultural conditions have improved recently and the 1922 harvest was normal. The altered situation in Russia has deprived Esthonian industry of much of its incentive to production. Timber is of prime importance, paper manufactured from wood-pulp making up a good proportion of the exports. The oil shale industry is still in the experimental stage. The output in 1920 was 483,000 tons, one-half of which was used in the cement industry, for which the shale has been found a suitable fuel.

Imports in 1922 included sugar, 14,413 t.; iron and steel, 15,698 t.; copper, 155 t.; glassware, 1532 t.; coal and coke, 90,906 t.; refined oil, 7169 y.; soda, 1192 t.; paints, 208 t. Exports are principally agricultural and textiles. There is a certain demand for British goods. Chemicals are imported mainly from Germany, though it is considered that crude chemicals of British origin, as distinct from drugs, might find a market.

SECOND ANNUAL REPORT OF THE SECRETARY OF MINES FOR THE YEAR ENDING DECEMBER 31, 1922, AND THE ANNUAL REPORT OF H.M. CHIEF INSPECTOR OF MINES FOR THE SAME PERIOD. *Mines Department. Pp.* 195. *H.M. Stationery Office,* 1923. *Price* 6*s.* 6*d.*

The first part of the Report is devoted to a review of the coal-mining industry in 1922, and it is pointed out that production steadily improved until a level approaching that of 1913 was reached, the total output being 249,606,864 tons. The increase in exports helped to compensate for the smaller home consumption. Altogether 229,725 surface and 933,029 underground workers were employed at coal mines, the numbers of persons killed and injured being 1105 and 185,497. The total number of workers employed at all mines in Great Britain was 1,175,280, in addition to 67,849 employed at quarries; 1160 persons were killed and 190,249 injured at mines and quarries.

The output of minerals in the United Kingdom is shown in the appended table.

	Output	
	1922	1921
	tons	tons
Iron ore and ironstone ..	6,867,512	3,477,955
Non-ferrous ores :		
Tin ore, dressed (black tin)	650	1,078
Lead ore, dressed	11,079	6,787
Zinc ore, dressed	1,620	814
Tungsten ore, dressed	3	—
Uranium ore, dressed	393	76
Copper precipitate	167	100
Manganese ore	250	514
Chromite, dressed	595	—

Minerals for Chemical and Allied Industries

	tons	tons
Arsenic (white) and arsenic soot	978	1,032
Arsenical pyrites	354	—
Iron pyrites	5,669	3,943
Bog ore	1,184	817
Ochre, umber, etc.	9,036	10,310
Salt	1,871,397	1,382,629
Barytes and witherite	40,949	24.669
Sulphate and strontium ..	4,711	6,622
Gypsum	257,460	264,840
China clay	666 834	435,844
Potter's clay	166,357	158,196
China stone	38,921	34,886
Alum shale	2,487	2,840
Soapstone	50	—
Oil shale	2,603,996	1,866,896
Petroleum	125	342
	cb. ft.	cb. ft.
Natural gas	100,000	100,000

Minerals used in Iron and Steel Making and other Smelting Processes

	tons	tons
Fluorspar	33,343	23,137
Ganister and silica rock ..	279,882	246,645
Fireclay	1,824,201	1,352,587

Minerals for Building and Roadmaking and for all other Purposes

	tons	tons
Limestone	9,418,678	7,334,064
Calcspar	6,453	1,798
Chalk	3,024,448	3,434,357
Sandstone (other than ganister and silica rock)	2,140,301	1,844,586
Slate	231,410	237,350
Clay and shale	6,407,715	8,348,367
Mica clay	12,984	3.083
Chert, flint, etc.	54,151	45,641
Gravel and sand	2,058,539	2,194,846
Moulding and pig-bed sand ..	195,345	238,852
Igneous rocks	5,927,964	5,700,770
Felsite, felspar and felstone ..	55,605	39,244

The report also contains sections devoted to reviews of the quarrying and mining industries (iron, tin, lead, zinc, radio-active minerals, minerals used in the chemical and allied industries, refractories, fluxes, building and road-making materials and oil borings), together with information on trade developments and prices. Health and safety in the mining and quarrying industries receive consideration, and research done to increase safety in mines or improve working conditions is described at length. The report concludes with a lengthy series of tables of statistics relating to the various industries.

OFFICIAL TRADE INTELLIGENCE

(From the Board of Trade Journal for Nov. 29)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Centrifugal pumps (tenders)	12652 and 12653 E.D. E.C. 2
,, ..	Steel blooms (tender) ..	12634 E.D./E.C./2
Belgium ..	Paper	575
Egypt ..	Linseed oil substitutes	594
,, ..	Type metal (tender) ..	11887 F.E./G.C. 2
Europe ..	Wire ropes, wire netting, galvanised sheets, hardware	8844/T.E.
Finland ..	Steel (tender) ..	8350 F.R./E.C. 2
Latvia ..	Pumping machinery ..	582
Lithuania ..	Asbestos, chemicals, hardware, rubber	583
,, ..	Sugar, caustic soda ..	585
Netherlands	Iron and steel ..	586
New Zealand	Glass jars	12575 E.D./M.C. 2
South Africa	Disinfectants	574
Spain ..	Copper sulphate ..	589
Sweden ..	Chemicals, oils, pig-iron	591, 592
Switzerland	Oils	593
United States	China clay, leather ..	596, 598
Yugoslavia ..	Leather (tender) ..	11874 F.E./M.C.

TARIFF CUSTOMS EXCISE

Germany.—The sugar tax is to be levied on net weight, and is to correspond for glucose to a rate of 14 per cent., and for other sugar to a rate of 35 per cent., of the works price of molasses at Magdeburg.

Poland.—Exports of scrap tin are prohibited.

Spain.—Certificates of origin are required for asbestos, glassware, hardware, iron and steel, copper, tin and other metals, scientific instruments, soap, perfumery, chemicals, paper, silk yarns, and rubber.

The death of Dr. J. Rosenbloom, of Pittsburgh, marks the loss of a medical practitioner well known in bio-chemical circles in the United States.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains a steady tone, both home trade and export continuing to take tolerably satisfactory quantities. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb. Inclined to stiffen in price.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton. Very little demand.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal. German charcoal is again being offered.

Acetate of Lime—	
Brown	£14—£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Competition being met with.
Solvent	6s. per gall. 40% O.P. Fair demand.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. per lb. Weaker, with limited demand.
Crude 60's	2s. 9d.—3s. per gall. Limited business for spot delivery. No market for forward delivery.
Acid Cresylic, 97/99	2s. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall. A little inquiry for forward delivery.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—9½d. per gall. Quiet.
Unstrained	8d.—9d. per gall. Quiet.

Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil Heavy Standard Specification	8½d.—9½d. per gall. according to grade and district. Good business being done.
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s.—1s. 2d. per gall. Market weak.
Solvent 90/190	1s.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 per ton.
Flaked	£19 per ton.
Pitch, medium soft	120s.—130s. per ton. according to district and time of delivery. Little business. Market difficult. Little inquiry forward.
Pyridine—90/140	21s.—23s. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 8d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 8d. per lb. 100% basis d/d
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 7d. per lb. d/d. Drums extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

English makers are steadily gaining ground in the manufacture of pharmaceutical chemicals with the aid of the Safeguarding of Industries Act, and whilst the present position in Germany continues supplies of chemicals manufactured abroad on a low exchange basis will gradually disappear from the market.

Acid, Acetic 80 % B. P.	£48 per ton.
Acid, Acetyl Salicylic	3s. 9d. per lb. Very firm. Makers fully occupied. Demand exceeds supply.
Acid, Benzoic	B.P. quality almost unobtainable. Commercial quality offered forward at 2s. 3d. per lb. for cwt. lots.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5%, for ton lots. Dearer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d. per lb. Very firm market. Expected to advance if demand continues.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5 %. Firmer.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 3s. 3d. per lb. on a short market. No supplies from Continent.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. 3d.—5s. per lb. for English make.
Ammon. Carbonate B.P.	£27 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Continental prices much higher.
Barbitone	18s. per lb. Slightly higher and in shorter supply.
Benzonaphthol	4s. 9d. per lb.
Bismuth Salts	A steady market. Prices according to quantity :

Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	
Potassium	10d. per lb. Remain very firm. Continental prices advancing.
Ammonium	11d. ,,
Sodium	10d. ,,
Calcium Lactate	2s. 9d. per lb. for best English make. Inferior Continental supplies have ceased.
Chloral Hydrate	4s. 3d. per lb. Position very firm and active.
Chloroform	2s. per lb. for cwt. lots. More active.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 14s. per lb.
Hexamine	4s. 6d. per lb. for foreign makes. Manufacture in England has been discontinued since formaldehyde was removed from the dutiable list.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate— Light Commercial	£36 per ton net.
Magnesium Oxide— Light Commercial	£72 10s. per ton, less 2½%. Reduced by £5 per ton.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quality and quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 65s. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	2s. 11d. per lb. for carboys. Brisk market. Higher values expected.
Methyl Sulphonal	22s. per lb.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 7d. per lb. In shorter supply.
Phenacetin	7s. 6d. per lb. Steady market. English makers fully employed. Foreign supplies shorter.
Phenazone	8s. 9d. per lb. In short supply.
Phenolphthalein	8s. per lb. Very firm.
Potass. Bitartrate— 99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Permanganate	9½d. per lb. for B.P. crystal. Shortage of foreign supplies has enabled English makers to regain lost ground.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Salol	4s. per lb.
Silver proteinate	10s. 6d. per lb. Quiet.
Sod. Benzoate	3s. 6d. per lb. Very scarce.
Sod. Citrate, B.P.C., 1923	1s. 5d.—1s. 9d. per lb., according to quantity.
Sod. Hyposulphite— Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 11d. per lb., and Crystal at 3s. per lb. Firm and very active.
Sod. Sulphide— Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	14s. 6d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	4s. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	9s. 6d. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s. 9d. to 13s. 6d. per lb.
Heliotropine	8s. 6d. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	20s. ,, ,,
Linalyl Acetate	20s. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Ketone	47s. 6d. ,, ,,
Musk Xylol	13s. 6d ,, ,,
Nerolin	4s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,
Rhodinol	60s. ,, ,,
Safrol	1s. 10d. ,, ,,

Terpineol	3s. „ „
Vanillin	25s. 3d.—26s. 6d. per lb. Firm with steady demand. Raw materials dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil..	1s. 11d. „ „
Bergamot Oil	13s. 3d. „ „ spot.
Bourbon Geranium Oil..	37s. „ „
Camphor Oil	75s. per cwt.
Cananga Oil, Java ..	9s. 6d. per lb.
Cinnamon Oil, Leaf ..	5d. per oz.
Cassia Oil 80/85% ..	11s. 6d. per lb.
Citronella Oil—	
Java 85/90% ..	4s. 9d. „ „
Ceylon..	Very little on offer.
Clove Oil..	10s. 6d. per lb.
Eucalyptus Oil 70/75%..	2s. 6d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil	2s. 10d. per lb. Higher prices expected.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet ..	11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil ..	24s. 6d. per lb.
Peppermint Oil—	
English	70s. per lb. Market very unsteady.
Wayne County ..	15s. 6d. per lb. Market very unsteady.
Japanese	12s. 6d. per lb. Market very unsteady.
Petitgrain Oil	9s. 6d. per lb. Dearer.

TRADE NOTES

Trade Information

Filter-Cel is a product introduced by the Celite Products Corporation, Victoria Street, London, to make it possible to filter dense liquors that formerly could only be handled by gravity filters of the bag type or by tedious settling processes. Dense liquors yield a tightly packed non-porous cake that prevents filtration, but if Filter-Cel is mixed with such liquor it builds up with the material on the filter cloth a thick porous cake with channels for the flow of the filtrate and filtration becomes possible. Only small quantities of Filter-Cel are added to the liquid prior to filtration, and after it is completely mixed filtration is begun. It should always be used with a retaining medium such as cotton, woollen or wire cloths or fine metal screens, and it can be used in conjunction with all types of filter presses. Sugars, syrups, molasses, glucose yield a clear sparkling filtrate when Filter-Cel is used in small quantity, and it also is employed in the filtration of cider, fruit juices, cereal beverages, fats and oils, dyestuffs, magnesia solutions, tannic acid, varnish, vinegar, waxes, and wines, to mention only a few of its many applications. With its use the capacity of the filter is increased, operating costs are reduced, recovery is increased and the appearance of the filtrates is improved. Filter-Cel, it is stated, is inert and does not affect in any way the chemical composition, taste, or odour of the liquor.

Gas Supply for laboratories situated in districts remote from town's gas has in the past been a serious problem. A solution is, however, provided by the oil-gas apparatus, supplied by Mansfield and Sons, Ltd., of Hamilton Square, Birkenhead. This apparatus enables an efficient substitute for town's gas in the form of oil-gas of some 1350 B.Th.U. per cb. ft. to be manufactured by unskilled labour from any kind of heavy oil or even animal or vegetable oil and fat. Such gas can be used for work varying from heating a test-tube to melting refractory ores, and the apparatus is designed to give durability as well as simple, efficient and economic working. In addition to oil-gas apparatus, Messrs. Mansfield also supply a variety of appliances, such as bunsens, burners, injector and combustion furnaces, ovens, blowpipes and other laboratory apparatus for use in conjunction with oil-gas.

Asbestos is one of those widely-used industrial materials of which little is heard. Yet, owing to its resistance to the attack of mineral acids, it is of particular importance to the chemical and especially the sulphuric-acid manufacturer. For such use it is imperative that the asbestos should be of 100 per cent. purity and free from organic matter. This requisite is, according to a circular we have received, met by the fibres, cloths and yarns manufactured by the Cape Asbestos Co., Ltd., of London, a firm which supplies asbestos in all shapes and forms for industrial use. Net cloth to hold the platinum catalyst in the oleum process, joints for fume mains in nitric-acid plants, packing for acid pumps, filter cloth or fibre for filtering corrosive liquors, acid-resisting cement, diaphragm cloths for electrolysis, asbestos clothing, heat insulation on pipe lines, mattress covers for vats, stills, ovens and the like are but a few examples of the many uses to which this versatile material is put by the Cape Asbestos Co., and even then new uses for asbestos in chemical industry are continually arising.

A Gold Medal has been awarded at the Barcelona Trade Exhibition to P. V. Brand leather cloth, which is made by the British Pluvinsin Co., of Manchester, a company under the control of Nobel Industries, Ltd., of London.

Rubber Supplies

The United States Rubber Co. has concluded a contract with a number of large companies (including two Belgian firms) of Kuala Lumpur, for the supply of 300 tons of rubber monthly. Some of this rubber will be treated by the Hopkinson process at Port Swettenham (Malaya), where a factory will be installed by the American company. Stores will be established, so that latex can be sent by rail to Port Swettenham.

Development of Copper Deposits in India

As a result of recent investigations in the Singbhum district of Chota Nagpur (the property of the Cordoba Copper Co.) a bed of rich mineral territory has been discovered, a section of which has already been prepared for development. Special attention has been given to the Mosaboni mine, where 1576 feet have been driven on copper-bearing lodes. Of this distance, 691 ft. were on ore of an average assay value of 4·66 per cent. copper over an average width of 46 inches. In consequence of the work accomplished at Surda and Dhobani, applications for mining leases have been made for these two areas and also for the Mosaboni mine.

German Petroleum Output in 1922

Natural oil production in Germany is very small. The 1922 output, 45,044 tons, amounted only to 0·04 per cent. of the world's total. Apart from the loss of Alsace-Lorraine, an important source, production has declined from the pre-war figure. In 1908 140,900 t. was obtained within the old boundaries. By 1913 this had fallen to 121,000 t., or 71,400 t. without Alsace-Lorraine, and in 1920 the output was only 34,800 t. The recent increase in output is due to fresh borings in Hanover, the most important oil-bearing district of Germany.

Fertiliser Industry in Germany

A report from Berlin states that in consequence of the depreciation of the mark, an agreement has been made by the representatives of the Government, agriculturists, and the nitrogen industry that the price of rye is to be the basis for fixing the price of nitrogen, the price of 140 kg. of rye being taken as that of 100 kg. of ammonium sulphate. While the nitrogen industry is forced, on account of political conditions, to purchase raw materials from abroad, a supplementary charge for these will be made. The price of calcium cyanamide is to be fixed at eight-ninths and that of sodium nitrate at one and one-ninth of the price of sulphate of ammonia.

Sugar Beet Crop in Hungary

It is estimated that the 1923 beet crop will yield 100,000 tons of sugar. Of this quantity, 60,000 t. are required for domestic consumption, and the remainder will be exported at an approximate value of £800,000 according to present London market prices. Despite the autumn drought, the quality of the beet and the sugar content are reported to be good. The area sown in 1923 was 94.728 cadastral yokes which produced 8·81 million quintals of beet, as compared with 62.598 cadastral yokes and 7·11 million quintals in 1922. Although there is a considerable demand for Hungarian sugar in the Levant and the East, it is probable that some portion will be sent to the London market.

French Company News

The Société de Petits Fils de F. de Wendel et Cie is about to erect a new battery of coke ovens at Moyeuvre-le-Grand (Moselle). This company has now lit six out of ten blast furnaces in its works at Patural.

The "Société générale pour la fabrication de matières plastiques" and the "Société industrielle du celluloid" are to amalgamate under the title "Société industrielle des Matières Plastiques."

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES | LONDON, DECEMBER 14, 1923 | No. 50

EDITORIAL

IF we rest a moment from our distillations, crystallisations, resolutions and precipitations, and take stock of the present state of chemistry, we can hardly fail to be astonished by the disparity between the enormous number of observational facts known, and the extreme paucity of the theories which vivify them. It was not always so: in the days of alchemy the theories were legion and the facts were comparatively few—and both states are bad for chemistry. There are, indeed, two factors essential to scientific progress—ideas and observations. It is idle to discuss which of the two is the more important, since it is perfectly clear that each is indispensable to the other. But it is necessary to insist upon the value of the one when the other appears to be unduly worshipped. The alchemists paid far too much attention to the products of the imagination and far too little to those of the laboratory; at the present day the pendulum has swung very largely to the other side, and a constant stream of more or less uninspired routine work issues with a mechanical and depressing regularity. The output of fruitful ideas bears no sort of relation to the mass of empirical data available, except in one or two conspicuous cases which will occur to our readers at once.

Consider, for example, the ionic theory. Here we have a theory which has remained in practically the same state in which it was first suggested by Arrhenius nearly forty years ago. The comparatively few facts it was intended to cover in its early days it certainly explained fairly well, but what real progress has it made since? Except for dilute solutions it has had to be supported in almost every direction by subsidiary and often fantastic hypotheses, and even with the aid of these it does not give a very convincing picture. In short, to us it appears to be in very much the same kind of position as that which was occupied by the phlogiston theory in its declining days. Both theories explained, to contemporary satisfaction, the facts which led to their formulation, and both became vaguer and vaguer as the number of relevant facts increased. The ionic theory, of course, is based upon a much larger and much more varied absolute number of facts than those correlated by phlogiston, yet is it any greater if compared with the whole contemporaneous field of chemical knowledge? How long will it be before the theory of ions goes the same way as the theory of phlogiston—the common way, indeed, of all scientific theories? It is a platitude to say that no theory is immortal, but it may not be useless to repeat that no theory is "correct" and none "incorrect." To apply the terms *right* and *wrong* to a chemical theory is to avow oneself destitute of the conception of the nature of scientific truth, yet how often do we find it said that, for example, Lavoisier showed that the old theory of combustion was "incorrect," and substituted for it the "correct" one! A theory may be adequate or inadequate to explain various sequences of phenomena, but it can never be said to be absolutely true; with absolute truth, in fact (if there be such a thing), science in its present embryonic stage of development has nothing whatever to do and, as far as we can see, may never have.

Dogma in chemistry, is a fatal handicap, as we all recognise unhesitatingly, except where our own favourite dogmas are concerned, but are we doing all we can to train the younger generations of chemists to a splendid irreverence for established chemical creeds? Or are we allowing the impressive grandeur of modern chemistry to hypnotise them into the belief that, in chemical theory, all is for the best in the best of all possible worlds? It is probably within the experience of the majority of us that the tendency lies very markedly in the second of these two directions, and it therefore behoves us to be up and doing, else we shall produce not chemists, but technicians.

What is needed is a different outlook and a better realisation of the essentially pragmatic nature of scientific truth, otherwise our theories, instead of being tools with which we hammer and carve and blast our way forward, will become superstitious creeds with which we mumble ourselves into a state of ecstasy. The best corrective of the attitude of slavish and blind adoration of the theories of the present is a study of the rise, development and subsequent fate of theories of the past. Perhaps a thorough training in the philosophy of science would serve the purpose equally well, but we cannot all be philosophers, and in many of us the very word "philosophy" arouses a vigorous inhibitive complex, due no doubt to our severely practical nature. In the same way, it is often impossible to get a man to react to theoretical ethics who will yet respond immediately to "The case of Hezekiah Smith: An Awful Warning to Sinners!" It is for this reason that we believe that the systematic study of the history of his subject should be made an integral part of the chemist's training. The time is past when the history of chemistry could be considered as a subject fit merely for the spare moments of the "practical" chemist—a pastime with which he might appropriately beguile his leisure. There is a real need now for men who will undertake historical research in chemistry as their main object in life, who will adopt the same critical attitude, employ the same acumen, and lavish the same unselfish care in rendering the development of the science plain and intelligible to the non-specialist, as are characteristic of the researches with glasses and test-tubes. That their work would be fruitful cannot be doubted: the arid regions of facts, with all their potential wealth, need to be fertilised with fecund ideas, and, while the man of genius must remain a mystery, yet the average mind can be trained to produce ideas with as great ease as the candidate for a doctorate produces new compounds. Let us show the new disciple that theories are not sacrosanct, by holding up to his gaze examples of the past; let us instil into his mind the continuity of chemical thought and its slow evolution throughout the ages, and let us encourage him to realise that chemistry is no cut and dried science in which all the main conceptions are impregnably established, so that the most we can hope to do is to add a brick here or to polish a rough surface there. All this and much more we could do by insisting that he should have an adequate knowledge of the growth of his science. The University of London has a lecturer on the History of Science: we trust it will not be long before every academic chemical department has its own lecturer on the History of Chemistry, whose services to the common cause will be recognised as of at least equal value with those of his colleagues in the laboratories.

* * *

Moving about the chemical world to-day one hears continual comment on the embarrasing growth of chemical science and the impossibility of keeping touch even with the main developments. The elders are bewildered by the pace and begin to consider what is going to happen to the thing they used to know for certain as solid chemistry. They feel rather as they do in a motor car when their nephew "lets her rip"—it is very wonderful, but after all there was something more restful in the less wonderful progress of a carriage and pair. The young man fresh from the University, on the other hand, more than ever feels how very old his elders are, how old-fashioned the foundation on which their structure of chemical knowledge was erected, how tremendously things must have changed since their young days.

Each of these extremes may be forgiven, they are indeed always with us and always will be. But between them we meet men in the fullness and maturity of vigour who are really much distracted by the flood of new knowledge. This is particularly the case among teachers. They will tell you two things in particular. One is that their lecture courses become unmanageable; the changes taking place, not only by the accretion of new knowledge but by far-reaching changes at the foundation, mean that a great deal of the old has simply to be jettisoned, not because it is unimportant, but because a place must be made for the new. There is now a much longer story that must be told of that part of chemistry which is not detail—a part where the experienced man is of most use as a guide. The other thing that you will be told is that young men coming to the staff from centres where the new knowledge is growing most rapidly are often amazingly ignorant of some of the older things which really are still indispensable for the right equipment of a chemist.

These facts suggest the enquiry—is it not time that we considered a re-ordering of the science which is now included under the word chemistry? Fifty years ago organic chemistry was still generally treated as an extra on chemistry proper, which included the general philosophy of the science and the systematic chemistry of all the elements. The increasing magnitude and importance of organic chemistry were clearly marked in this country when in 1874 Sir Henry Roscoe brought about the appointment of Carl Schorlemmer to the first British Chair of Organic Chemistry. The chief difficulty, however, has arisen from the rapid growth of chemistry on the physical side and the treatment of physical chemistry as a branch separable in the same way as organic chemistry from the main trunk of the science.

This has tended to make havoc of inorganic chemistry. It is absurd to talk of teaching inorganic chemistry apart from the general philosophy of the science. Certainly a stuffing process can be, and sometimes is, set up, reducing the subject to a sort of recited pharmacopœia. The only satisfactory solution would appear to lie in the inorganic chemist recovering a considerable fraction of what has been filched from him by the physical chemist, letting this be used as the life-blood of his teaching and leaving out a great deal of the detail of inorganic chemistry. There would still remain an ample field of the higher range of physical chemistry for the separate specialist teacher. It would seem to be a calamity if students are not to be given in the first instance a good measure of strictly unhyphenated chemistry by a first-class teacher.

THE BOHR ATOM AND COVALENCY

By N. V. SIDGWICK, D.Sc., F.R.S.

Dr. Main Smith's article on the Bohr atom (this vol., p. 1073) is chiefly devoted to a severe reprobation of my attempts to extend the Bohr theory to non-polar compounds.

He begins with a criticism of Prof. Bohr's theory, which may be summed up under three heads. The first is that though the theory accounts for the existence of positively charged ions, " no cognisance appears to be taken of the much more important fact that no atomic ions are capable of existence carrying more than one negative charge." The fact may, perhaps, be disputed on the ground of the existence of O^{--} and S^{--}; but apart from this question, any dynamical model which assumes the electrons to be held by the attraction of a positive nucleus gives a reason why negative ions should be less stable than positive. The firmness with which the outermost electron is held depends in the first instance on the positive charge on the rest of the atom. In an ion with a single negative charge, the positive charge is zero : in a divalent anion the charge on the rest of the atom is negative. This explains why triply charged anions are unknown, and doubly charged, if they exist at all, are rare. Singly charged negative ions can only be formed when their electronic arrangement is of unusual stability, and that is why they only occur when their effective atomic number is that of an inert gas.

The second point of attack is that if one of the valency electrons of aluminium occupies a 3_2 orbit, and the other two 3_1 orbits, aluminium should behave as a univalent element : from which he draws " many inferences " of an improbable character. But even if the three electrons were in orbits of the same type, in which case he would admit the trivalency, the work required for the successive steps of the ionisation would be in the ratio 1 : 4 : 9. This difference is not sufficient to prevent atoms from reverting to the inert gas type by the loss of two or three electrons ; and the fact that with aluminium one electron is in a 3_2 and the other two in 3_1 orbits will not affect the result, unless the ratio of energy levels of a 3_1 and a 3_2 orbit is large in comparison with these ratios, which Dr. Main Smith has not ventured to assert.

The third series of criticisms, that the Bohr theory does not account for the formation of complex ions, of carbon monoxide, of nitric oxide, for the absence of compounds of nitrogen and fluorine, and so forth, may be summed up by saying that it does not deal with non-polar linkages. This is admitted. It is precisely because the dynamics of orbits in which more than one nucleus is concerned is too complicated to be dealt with at present by physical methods, that I have made the attempt to approach the subject on the chemical side.

Dr. Main Smith then proceeds to deal with me. He begins by attacking the view, suggested seven years ago by Prof. G. N. Lewis, and now accepted by the majority of chemists interested in the subject, that a non-ionised link is due to the sharing of two electrons.* He says (p. 1075), " It might be supposed " from my accepting this theory " that the existence of covalencies was a proven fact. Actually there is no evidence to support it." A little later he says, " It is not suggested," *i.e.* by himself, " that the covalency postulate does not represent a reality." If it represents a reality, I should have thought that there must be some evidence for it. However, it seems that an inorganic covalency is formed by a single shared electron, but that when we enter " the realm of undoubted aliphatic and aromatic chemistry," two are required. The frontier of this realm is defined by the occurrence of " straight chains containing more than three carbon atoms."

This subordination of chemical laws to the requirements of text-books does not appeal to me. The great advantage of the application of electronic ideas to chemistry seems to me to lie in the fact that it enables us to regard all questions of structure, whether organic or inorganic, from a single point of view. Elsewhere (this vol., p. 848), Dr. Main Smith lays great stress on simplicity as a test of the truth of a chemical theory. This simplicity, it seems, is secured by proclaiming loudly that all valency is one, and then immediately dividing it into two, or, as it would now appear, into three kinds—polar valencies, one-electron covalencies for inorganic use, and two-electron covalencies for use in " undoubted " organic chemistry.

---

* " One of the biggest advances yet made in the study of valency."—Andrade, *Structure of the Atom*, 1923, p. 244, note.

Dr. Main Smith argues that polar and non-polar valencies (though he provides a separate mechanism for them) are "practically undistinguishable," because solutions of some complex salts (such as K_2SiF_6) give reactions of the simple ions. He does not explain why other complex salts fail to give these reactions. The facts were accounted for by Werner by the very probable assumption that the complex dissociates in solution to a greater or less extent. Dr. Main Smith seems to have granted himself a dispensation from the edict which he promulgated against Prof. Lowry, forbidding anyone to tamper with the Werner theory. His whole treatment of the relation between ionisable and non-ionisable links is opposed to Werner's view (see, for example, *Neuere Anschauungen*, 1913, p. 72), and I notice that he has abandoned the use of the square bracket, by which Werner emphasised this fundamental distinction.

The conception that there are two kinds of valency, one due to a transferred electron, and the other to two shared electrons, is, of course, the basis of all my suggestions. If it is rejected, they fall to the ground at once. If it is accepted, the idea of effective atomic number follows of necessity, and is not, as Dr. Main Smith seems to think, a new assumption. If we know the structure of the molecule, we know the number of electrons surrounding any atom within it, and that is all that the effective atomic number means. Some of these electrons are "lone" electrons, the sole property of the atom: the rest are shared with other atoms. These two classes must obviously be distinguished from one another, though we need not make any assumption as to the orbits of the shared electrons, except that they are different from those of the unshared electrons. Since we know from Prof. Bohr's theory what are the stable arrangements of electrons in an isolated atom, it is natural to try to arrange the electrons in a combined atom in a similar way; and this is what I have done. Dr. Main Smith seems to think that it follows that an element which in a compound has a given effective atomic number must behave like an isolated atom of the same atomic number, regardless of the fact that some of its electrons are shared. But this is just the opposite of my view, as he would have seen if he had read my paper with any care. I have always considered the effective atomic numbers strictly in relation to the covalency number. To take his own example, in a compound $K[AlF_4]$ the aluminium has the effective atomic number 18. This is stable because the atom (like silicon in SiH_4) can have the arrangement (2) (4, 4) (*4*, *4*), differing from that of argon only in that eight of the electrons are shared. In $Na_3[AlF_6]$ the effective atomic number of the aluminium is 22 and the covalency 6 (as it is also in AlA_3,* and in the central atoms of $[SiA_3]Cl$, $K_2[SiF_6]$, SF_6, and possibly of $[Mg(NH_3)_6]Cl_2$. The number 22 occurs in combination with a covalency of 6, but not without it, in many stable compounds. It must, therefore, be possible to have a stable arrangement of 22 electrons when 12 of them are shared. I suggest that this may be expressed by writing the six pairs of shared electrons as two subgroups outside the unshared electrons: (2) (4, 4) (*6*, *6*). Dr. Main Smith says that the number 22 must indicate activity, because it is the atomic number of titanium. He entirely ignores the covalency, which is an essential part of my suggestion, and the fact that the activity of titanium is due to the structure (2) (4, 4) (4, 4, 2) (2), which is not possible for a 6-covalent atom, since it does not contain any group of 12 electrons. He says that the numbers in my groups "have no necessity beyond a desire to obtain an inert gas structure, or, failing that, any structure that looks symmetrical." The phrase "failing that" is misleading. It is essential that the number of the 6-covalent atom should be 22 rather than 18, which would lead to (2) (4) (*6*, *6*); this is not a stable grouping, and that is why the effective atomic number 18 does not occur with a covalency of 6. The total number has a "necessity" on the electronic theory, and if it can be shown that when the compound is stable this number can be expressed in a symmetrical way, that, I submit, is an advance of some importance. In titanium, as we know, the electrons are grouped in an unsymmetrical way, and that is why the element is active. Of course the word "symmetrical" requires to be defined more precisely. This can only be done by the further examination of effective atomic numbers; but I have tried to point out some of the conditions of symmetry or stability, founding my ideas of symmetry on those groupings which Prof. Bohr finds to be exceptionally stable in the isolated atom.

Now we come to the rule relating the covalency to the position of the atom in the periodic table. Here I must admit that in my paper in this *Journal* (p. 901), I was led by a desire for brevity to state the rule in a manner open to misconception; and this has enabled Dr. Main Smith to draw a number of absurd conclusions from it. In my paper in the *Transactions* of the Faraday Society (Oct., 1923), I stated it in the form that "the highest covalency number is that of the subgroup" (meaning of course the maximum size of subgroup), "next to the largest completed group in the atom." The maximum size of the successive quantum groups and subgroups according to Prof. Bohr is :—

1-quantum group : $1 \times 2 = 2$
2-quantum group : $2 \times 4 = 8$
3-quantum group : $3 \times 6 = 18$
4-quantum group : $4 \times 8 = 32$

If the principal quantum number is n, the maximum number of subgroups is n, and the maximum number of electrons in each sub-group is $2n$. I may point out to Dr. Main Smith that this is a conclusion of the Bohr theory, and is not my invention. The rule which I proposed is this. If the atom in the compound has enough unshared electrons completely to fill n quantum groups (the number required being 2 for 1, 10 for 2, 28 for 3, and 60 for 4) its maximum covalency is equal to the maximum number of electrons in a subgroup of the $(n+1)^{th}$ quantum group. Dr. Main Smith has overlooked the word maximum, which was stated with reference to the covalency, and clearly implied with reference to the subgroup number. Now we never find that an atom in a compound has more lone electrons than it had in the isolated state. It, therefore, follows that no atom before neon (10) can have a higher covalency than 4, and no atom before nickel (28) a higher covalency than 6. Dr. Main Smith quotes certain substances whose formulæ appear to contradict this rule, and these I will discuss later. The rule certainly accords with the behaviour of the great majority of substances. It is well illustrated by the acetyl-acetonates. It accounts for the fact that aluminium can form AlA_3, while boron, though it also is trivalent, cannot form BA_3, and so forms $[BA_2]X$ instead; and that zirconium can form ZrA_4, while titanium can only reach $[TiA_3]X$. The test case in this group of elements is germanium. This in my view is the lightest of the quadrivalent elements which can form a compound of the 8-covalent type: $GeA_4 : 32+12=44=(2)\ (4,\ 4)\ (6,\ 6,\ 6)\ (\mathit{8},\ \mathit{8})$. The germanium derivative of acetyl-acetone has, however, not yet been described. The reason I gave for this rule, which seems a natural one, is this. In the uncombined atom a subgroup cannot reach its maximum size until the groups of lower quantum number are complete. Thus in the 3-quantum group you cannot have a subgroup of 6 unless the two fours of the 2-quantum group are present. In general, you cannot have any subgroups of $2n$ unless they are supported, so to speak, by the full set of subgroups of $2n—2$, $2n—4$, etc. In the same way it would seem that in the combined atom you cannot have a covalency of $2n$ (which involves two subgroups, or something like subgroups, of $2n$ shared electrons each) until you have a full group of unshared electrons of the $(n—1)^{th}$ quantum number established. Thus of the following formulæ :—

---

* For brevity I write A for the acetyl-acetonyl group.

(1) $BeA_2 \quad : \quad 4+6 = 10_4 = (2)\ (\mathit{4},\ \mathit{4})$
(2) $[BA_2]X : 5+6+1 = 10_4 = (2)\ (\mathit{4},\ \mathit{4})$
(3) $BA_3 \quad : \quad 5+9 = 14_4 = (2)\ (6,\ 6)$
(4) $AlA_3 \quad : \quad 13+9 = 22_6 = (2)\ (4,4)\ (6,6)$

(1), (2), and (4) comply with this rule, and represent actual compounds: (3) does not, since the sixes have no fours to support them, and accordingly no such compound as BA_3 exists. This rule is not proposed as an *a priori* principle of symmetry, but as a generalisation of the observed facts that certain of these compounds are formed, while others, which, apart from these ideas seem equally probable, are not. The rule takes the form to which Dr. Main Smith objects if we suppose that in these highly covalent compounds the lone electrons fill up completely as many of the lower groups as they can, and if we further assign to the covalency electrons a principal quantum number one more than that of the largest completely filled group. But as these assumptions are not obvious, and the last in particular (the assignment of a definite quantum number to the orbits of the shared electrons) is of doubtful validity, it is better to state the rule in the form which I have just explained.

If this form is adopted, it is obvious that it leads to none of the absurd conclusions which Dr. Main Smith deduces. But there still remains to be discussed the series of compounds which he quotes as indicating a higher covalency than the rule allows—compounds supposed to establish a covalency of 6 for boron, of 8 for titanium, of 12 for osmium, and even of 20 for aluminium and tantalum. Some of these do not seem at all to bear the interpretation which he puts on them if we take account of ionisation, or even of probable modifications of structure. Thus $[B(NH_3)_3]F_3$ would have a covalency of 3, and $[Ti(NH_3)_6]Cl_4$ of 6; H_3BF_6 may well be $B(F_2H)_3$, since F_2H is well established as a univalent ion. In the hexa-borotungstates $R_3B(W_2O_7)_6$ he would be a bold man who claimed to know the exact arrangement of the 55 atoms which form the complex. The rest of his selected compounds are open to an objection of a more general kind. Their formulæ express the composition of the solid phase, but no evidence is available, so far as I can discover, of the existence of such molecules in solution. Now in the case of hydrated salts it is generally admitted that there may be water molecules in the crystal which play no part in the molecular structure. Werner certainly took this view, and was often at pains to show that some of the water molecules entered into the constitution of the complex, while others did not. But if this is admitted for water it must certainly be admitted for ammonia likewise: and if for ammonia, why not for other molecules as well? We know from the X-ray results that the crystal unit may contain two or more molecules of the same substance. There is no sign that these are combined chemically: they are packed together in the crystal owing to the operation of crystalline forces, which are altogether subordinate to the forces connecting the atoms in a molecule. If the crystal structure is destroyed by fusion or solution, they separate again. Now if similar molecules can thus be joined crystallographically, why not dissimilar molecules? Why should not the substance $R_{15}TaF_{20}$, which Dr. Main Smith regards as evidence of a covalency of 20 in tantalum, really consist of, say, $R_3[TaF_8]+12\ RF$, forming separate molecules but one crystal unit? It may be said that this gives us great latitude in fixing the formulæ of complexes. The answer is that the composition and structure of a molecule must be determined by examining its properties in the liquid state before we can use it to establish or to overthrow any theories of valency. Werner was always careful to do this. By observing the number of ions formed from the compound in solution, by detecting its isomerism, and most conclusive of all, by producing instances of optical activity, he established a series of types of complex compounds about whose structure there was no doubt. Other methods of investigation can be employed. Non-polar compounds can be distinguished by their volatility, by their solubility in non-polar solvents, such as hydrocarbons,† and still better, if they dissolve in water without decomposition, by the non-conductance of the solution; their molecular weights can be measured in solution or in the vapour. The views I have expressed are founded on the behaviour of substances whose structures have been examined by methods of this kind.

Dr. Main Smith's remarks on hydrogen scarcely call for any reply. I agree with him that an electron cannot revolve in two different orbits at the same time; I also agree that 2-covalent hydrogen must have 4 electrons, only 2 of which can be in 1_1 orbits. If we are justified in giving the shared orbits any quantum numbers at all, the other two presumably occupy 2_1 orbits. But why should they not do so?

His remarks on the last page of his article as to the orbits of shared electrons are I am afraid beyond me. He says, "It is doubtful if the facts or the electrons are so simple or lie so close to the surface." However it may be with the facts, it is certain that the electrons (together with the protons) are the simplest things we know, and that the valency electrons are not only for most of the time near the surface, but constitute the surface, of the atoms. If the orbits of the two shared electrons encircle both nuclei, as he suggests, and as has been suggested before, it seems quite possible that one may be playing its part in the neighbourhood of one nucleus, while the other is doing the same for the other nucleus, and that in the course of a revolution each may change over from one nucleus to the other. The idea that a non-polar linkage is constituted of two electrons, which in some way count in the structure of both atoms is, as Prof. Lewis showed some years ago, a direct inference from the ordinary laws of valency and the conception of atomic number. No facts incompatible with it have yet been brought forward. If Dr. Main Smith can produce any, let him do so. If he claims that such linkages can equally well be formed of a single electron, let him show us, for a simple molecule, such as chlorine or methane, how this can be done. But he will need strong evidence to convince chemists of the truth of his distinction between organic and inorganic phenomena, or of his doctrine that new laws of valency come into being when we pass from propyl to butyl alcohol.

Dyson Perrins Laboratory,
Oxford
November 21, 1923

PERSONALIA

The U.S. National Research Council has appointed Mr. R. B. Sosman, of the Geophysical Laboratory, as American member on the Permanent Committee for the Standardisation of Physico-Chemical Symbols of the International Union of Pure and Applied Chemistry. The other members of the committee are Prof. E. Cohen, University of Utrecht, chairman; Prof. A. Findlay, University of Aberdeen; and Prof. Ch. Marie, the Sorbonne.

Monsieur Rivière has been appointed professor in charge of courses on the silicate industries and the gasification of fuels at the Central School of Arts and Manufactures, Paris. Monsieur Dufour has been appointed professor of general physics at the same school.

C. W. Parmelee, who has become Head of the Department of Ceramic Engineering at the University of Illinois, has been connected with the Institution since 1916 as professor of ceramic engineering, and during the past year has served as Acting Head.

* * *

The death is announced of Mr. H. Barrett, J.P., of the Phœnix Chemical Works.

The following deaths are announced from Germany: Prof. G. E. Emmerick, the founder of the Munich Photographic Institute, and of various photographic publications and associations; Dr. L. Grunmach, professor of experimental physics at the Berlin Technical *Hochschule*; D. H. Jordan-Mallinckrodt, founder and director of the Vereinigte-Glanzstoffabriken A.-G.; and Dr. A. Pfannenstiel.

---

† It is on these grounds that I think the structure recently proposed for basic beryllium acetate by Sir W. Bragg and Prof. Morgan (*Proc. Roy. Soc.*, 104, A, p. 440) is untenable. This substance boils at 330°, giving a normal vapour density, and is soluble in chloroform. In fact these authors themselves admit that "there is no sign of ionic dissociation throughout this group of beryllium compounds." But according to their formula the molecule contains 17 "non-valent, but charged atoms" (4 berylliums and 13 oxygens). This can only mean that the atoms in question are ions. The six $CH_3{\cdot}C-$ groups must presumably also be ions, since none of the other atoms have any valencies to which they could be attached. The molecule of this compound which shows "no sign of ionic dissociation" therefore consists of 23 ions. The structure which I have suggested (*Nature*, vol. III, p. 808, 1923), in which the positions of the atomic centres are the same as in the formula of Sir W. Bragg and Prof. Morgan, but the distribution of the electrons is different, providing non-ionisable linkages for all the atoms in the molecule, seems much more in accordance with the properties of the substance.

FORTHCOMING EVENTS

Dec. 17. THE FARADAY SOCIETY, at The Rooms of the Chemical Society, Burlington House, Piccadilly, W. 1, at 8 p.m. Discussion on the Report on Atmospheric Corrosion, to be opened by W. H. Vernon.

Dec. 17. INSTITUTION OF THE RUBBER INDUSTRY. The Kelvin Room of the Engineers' Club, Coventry Street, Piccadilly, W. "The Position of the Rubber Tyre Industry," by Col. Sealy Clarke.

Dec. 17. INSTITUTION OF MECHANICAL ENGINEERS, *Graduates' Section*, Storey's Gate, S.W. 1, at 7 p.m. "The Management of a Sand and Flint Quarry," by F. E. A. Manning.

Dec. 17. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, London, W.C. 2. Discussion on "Students in Electricity Undertakings."

Dec. 17. THE TEXTILE INSTITUTE, *London Section*, at 38, Bloomsbury Square, W.C. 1, at 7.30 p.m. Discussion on "Comparative Methods of Testing Textiles."

Dec. 19. ROYAL MICROSCOPICAL SOCIETY, 20, Hanover Square, London, W. 1, at 7.30 p.m. "Melanin Formation and its Relation to the Nucleolus in a Melanotic Sarcoma," by Dr. R. J. Ludford, Ph.D.

Dec. 20 INSTITUTION OF MINING AND METALLURGY, Burlington House, W. 1, at 5.30 p.m.

Dec. 20. INSTITUTION OF MECHANICAL ENGINEERS, *Manchester Section*, at The Engineers' Club, Albert Square, Manchester. "Exhaust Valve and Cylinder Head Temperatures in High-Speed Petrol Engines," by Prof. A. H. Gibson, D.Sc., and H. Wright Baker, M.Sc.

Dec. 20. INSTITUTION OF MECHANICAL ENGINEERS. *Birmingham Section*, at the Medical Theatre, The University, Edmund Street, Birmingham. "Engineering Uses of Rubber," by H. C. Young.

Dec. 20. SOCIETY OF CHEMICAL INDUSTRY, *Glasgow Section*. The Ramsay Chemical Dinner, to be held at the Ca'doro Restaurant, Glasgow.

Dec. 20. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "The Relation between the Glow of Phosphorus and the Formation of Ozone," by W. E. Downey. (2) "The Origin of Mutarotation and the Mechanism of Isomeric Change," by T. M. Lowry. (3) "The Action of Inorganic Haloids on Organo-metallic Compounds," by F. Challenger and F. Pritchard. (4) "Organo-derivatives of Bismuth. Part VII. Iodo- and Nitro-derivatives of Triphenylbismuthine," by J. F. Wilkinson and F. Challenger.

Dec. 21. SOCIETY OF DYERS AND COLOURISTS, *Manchester Section*, 36, George Street, Manchester. "The Dyeing of Cellulose Acetate Silk," by L. G. Lawrie.

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

NOTICE TO MEMBERS AND SUBSCRIBERS

The Annual Suscription falls due on January 1 next, and Members and Subscribers are reminded that no issues of the Journal for 1924 will be despatched to them until their subscriptions have been received at the Society's offices.

The formal applications for subscriptions will shortly be despatched to Members and Subscribers.

EXTRA COPIES OF ABSTRACTS

Members and subscribers may find it advantageous to have extra copies of the Abstracts section of the Journal printed on one side of the paper only, for filing purposes. The Society is prepared to supply these for the year 1924 in complete sets at a charge of £1 per set. Members and Subscribers who desire to avail themselves of this offer are requested to communicate with the General Secretary as soon as possible.

CHEMICAL ABSTRACTS

The Bureau of Chemical Abstracts, formed on the basis of an agreement between the Chemical Society and the Society of Chemical Industry, is making arrangements for the issue of Abstracts in two sections, namely (*a*) Pure Chemistry, and (*b*) Applied Chemistry. So far as 1924 is concerned, these sections will be practically of the same form as the Abstracts at present issued by the Chemical Society and the Society of Chemical Industry, respectively.

Members of the Society of Chemical Industry can procure the Abstracts in Pure Chemistry for 1924 for the sum of £1 10s. An order form will be sent out in a few days, together with the application for the 1924 subscription to the Society. This form, when completed and signed by the member, should be sent at once with the appropriate remittance direct to *The Chemical Society*.

DEATHS.

Barker, Hugh S. (elected 1902), of 131, Brownlow Hill, Liverpool, Laboratory Furnisher. On October 20, 1923.

Stead, Dr. J. E., F.R.S. (Original Member), of 11, Queen's Terrace, Middlesbrough, Metallurgical Chemist. On October 31, 1923.

Wilkie, John M. (elected 1903), of 5, Balmoral Avenue, West Bridgford, Notts, Analytical Chemist. On November 29, 1923.

SHAWINIGAN FALLS SECTION

In the absence of the chairman, Mr. R. A. Witherspoon, Dr. F. W. Skirrow presided over the meeting, held in the Cascade Inn, on November 21. After the routine business was disposed of Mr. G. S. Shaw read a paper on "Industrial Hydrogen."

In this paper a review was made of the new uses of hydrogen, chiefly in hydrogenation and in the synthesis of ammonia. In the manufacture of synthetic ammonia the main cost item was that of preparing the pure hydrogen and nitrogen. The chief industrial processes in use to-day were described, special attention being paid to the steam-iron and electrolytic methods of producing hydrogen. This last method was the most interesting to the Shawinigan Falls industry, on account of the cheap power available there. The cost of power in Shawinigan was within the limit set by the cell manufacturers as necssary in order to complete with the costs of the other methods for the manufacture of pure hydrogen. A description was also given of small installations generating hydrogen for experimental purposes with small outlay of capital, although higher cost per unit of hydrogen.

Mr. H. S. Reid followed with a paper on "Automobile Motor Fuels," in which he discussed the growth of gasoline production in the United States from about a quarter of a billion gallons in 1904 to a billion and a half in 1914, nearly five billion in 1920, and finally about six and a quarter billion in 1922. This at first came entirely from straight distillation of crude petroleum, but later was augmented by the light oils compressed from natural gas, and still later by "cracking" the heavier oils of petroleum. Cracking processes were becoming more efficient, and at present about 20 per cent. of the gasoline supply came from this source. Of the present world's production of about 850 million barrels of petroleum, considerably over half originated in the United States, and yet 36 million had to be imported to supply the demand.

It is estimated that at the present rate of consumption there are reserves in sight to last a thousand years, but unfortunately these are not well distributed, and some of the principal consuming countries find it hard to get adequate supplies. If the shortage became severe enough greatly to elevate the price of gasoline, shale oil deposits could be worked which would greatly increase the supply.

Ethyl alcohol was an ideal motor fuel and is used as a substitute for gasoline in Europe, but could never come into very general use on account of the restricted supply. If the three main sources of cheap alcohol in the United States, viz., corn, molasses and wood waste, were thoroughly exploited, the resulting alcohol would run the motors of the country for only nine weeks. Benzol was also a satisfactory motor fuel, but the possible production also was inadequate. Mixtures of benzol and alcohol were used with success in Germany during the war, and were used to-day in such countries as Sweden, which are unfavourably located for gasoline supply. The quality of gasoline can be much improved by proper admixture with small amounts of other substances, such as ethyl lead, aniline and iodine, and considerable research work is being done in this field. The General Motors Corporation had lately put on the market a gasoline treated with "ethyl fluid," which is said largely to eliminate knocking and carbon deposits.

In discussing the papers, Dr. Skirrow suggested that in the future the two subjects, hydrogen and motor fuels, might not seem so remotely related, and recalled certain experiments in Germany where artificial coal, made by exposing wood fibres to immense pressures, had been further changed to a petroleum-like substance by treating it with hydrogen, also under pressure, thus possibly reproducing the way in which nature makes our oil deposits.

MANCHESTER SECTION

A joint meeting of the Manchester sections of the Institution of the Rubber Industry and the Society of Chemical Industry was held on December 7. Dr. H. Levinstein presided, and Mr. J. H. Mandleberg, M.A., chairman of the local section of the Institution of the Rubber Industry, was present. Dr. Levinstein said that at the inception of the Society the Manchester section had many members representing the rubber industry, and, although that industry had so developed that it required an institution of its own, the parent Society embraced all chemists and there was a very close connexion between the chemical and rubber industries. Rubber accelerators were first used at the Faber Fabrik at Leberkusen, where during the war some 3000 tons of synthetic rubber was produced.

A paper on "Methods to be Adopted in Comparing the Activity of Various Accelerators" was read by Mr. G. C. Martin (Superintendent, Rubber Investigations, Imperial Institute). The potency of an accelerator was affected by the purity of the rubber, and some investigators used the acceleration factor $k=\frac{S_a}{S_r}$ where k is the acceleration factor, S_a the rate of vulcanisation in the presence of the accelerator, and S_r the rate of vulcanisation of the same mixing in the absence of the accelerator. This factor depended upon the ratio of two values, both of which were affected by the raw rubber used and not always in the same direction. If the concentration of the accelerator was doubled the acceleration factor was less than $2k$, but recent work suggested that it might be possible to deduce an accelerator constant which was independent of the concentration. Different accelerators had specific effects, but the specific nature was not so important as potency, a factor which was affected by the sulphur content. Other factors affecting vulcanisation were the degree of fineness of the zinc oxide and the temperature. It could be seen that the acceleration factor was not entirely constant under simple alterations of conditions, but the variations in value were not sufficiently great to prevent the factor from being useful, especially for commercial description. The factor should be used for 1 per cent. concentration of the accelerator in the rubber, and the conditions under which it had been determined given. Physical methods of measuring the rate of cure gave larger values for the acceleration factor than the chemical method, but the two sets of values appeared to be inter-related.

A second paper, entitled "The Analysis of Organic Rubber Vulcanising Accelerators," by T. Callan, M.Sc., Ph.D., and N. Strafford, B.Sc., A.I.C., was read by Dr. Callan. Dr. Callan said that much work had been carried out on the comparative vulcanising powers of various accelerators, but very often only the trade-name of the accelerator used was stated, so that it was often difficult to co-ordinate the results of different workers, particularly as the same chemical substance might occur commercially under various proprietary names, and this had undoubtedly checked progress in the use of accelerators in the rubber industry. It is therefore desirable that there should be reliable methods available for the identification and estimation of the many widely different substances used as accelerators.

As there is little published information on the subject, the authors have put forward methods for the identification and quantitative determination of a number of the more widely used organic accelerators, including phenolic, nitroso, and amino compounds, the aryl guanidines such as diphenylguanidine and triphenylguanidine, the biguanides such as *o*-tolylbiguanide, thiocarbanilide and the substituted thiocarbanilides prepared from amines other than aniline, *e.g.*, toluidine, aldehyde ammonia, the derivatives of dithiocarbamic acid such as zinc diethyldithiocarbamate, diethylammonium diethyldithiocarbamate, piperidine piperidyl dithiocarbamate, and their oxidation products, the thiuram disulphides. Most of the methods put forward involve simple volumetric determinations, using ordinary standard solutions. The authors have also determined the physical constants of a number of purified compounds and their derivatives used as accelerators, such data being of considerable value in elucidating the composition of an accelerator requiring to be identified.

INSTITUTE OF CHEMISTRY

The annual dinner was held on December 10, in the Hotel Victoria, under the presidency of Mr. A. Chaston Chapman, F.R.S.

Viscount Haldane, in submitting the toast of "The Institute," said the science of the 'forties and 'fifties had very little relation to industry; consequently, manufacturers were able to get on very well without it, and they beat the world at production. Then a change began to set in, and the new discoveries of science began to be applied to industry. For a time we fell behind, but our methods had since changed. In this century the production of young men of science had gone on with extraordinary vigour, and while they might not produce as many here as were produced on the Continent, he was sure we produced more peaks and pinnacles than were produced there. The problem of the future is to see that more science is applied to industry, and that it is organised in the best way. We are quite capable of holding our own in the world, and the only question is how much we shall suffer through going too slowly.

Mr. A. Chaston Chapman, replying, recalled the purpose for which the Institute was founded in 1877, and said that since those early days its record was one of uninterrupted progress, and in the short space of the past thirty or forty years a great and powerful profession had been built up. Whether we regarded chemistry as essential to an understanding of the world in which we lived, as an agent which had done so much to transform the life of man, as one of the most powerful factors in the creation of material wealth, or, finally, as that department of knowledge on which our national prosperity and our national security so largely depended, its supreme importance was equally manifest. During the war he would not say that chemists were actually discovered, but for the first time the nature of their activities and their great usefulness were widely recognised. Notwithstanding this, could it be said that since the termination of the war the influence of chemists as a body had increased? He believed not, but rather the reverse. He hoped not only that the guests would take away with them recollections of a pleasant evening, but that they would do what they could to increase the general knowledge and better understanding of the services which chemistry was ever rendering to the community.

The toast of the "Houses of Parliament" was proposed by Prof. A. Smithells, F.R.S., and, Viscount Haldane, responding, said that nobody knew what the future would bring forth, but if the future brought forth any changes of a striking nature his impression was that the House of Lords would prove itself equal to the emergency. Mr. Robert C. Nesbitt, M.P., replied for the Lower House.

The toast of the "Forces" was submitted by Sir Robert Robertson, and, responding for the Royal Navy, Captain J. C. W. Henley, R.N., Director of Naval Ordnance, emphasised the extent to which naval efficiency depended upon the chemist. Lieut.-General Sir Noel Birch, Master-General of the Ordnance, replying for the Army, said that in the late war chemists saved us from defeat. In 1915, when the Germans made their gas attack, the chemists came to our assistance and beat the German at his own game. Air Vice-Marshal Sir W. G. H. Salmond also replied.

To the toast of "The Civil Service," proposed by Sir Herbert Jackson, Sir L. Amherst Selby-Bigge, Permanent Secretary, Board of Education, responded.

Viscount Burnham, in proposing the toast of "Science in Industry," observed that in the false security of the industrial life of the last century we allowed manufacture to be largely developed in Germany and America. Late, but not too late, we discovered our default, and we had been trying to think ahead of ourselves ever since. He was glad to say that the benefit of the trained mind, as well as the trained hand, was being recognised every day more and more by the employers of the country. There were no more convinced believers in technical education than the enlightened captains of our industries to-day. Most of the troubles of their industries had a chemical origin. No works could be called efficient or progressive without the works chemist. It was said in derision of a French statesman that he followed the policy of yesterday by the methods of to-morrow. That was what they all ought to do to regain the primacy of England in the trade of the world. That policy was the policy of the merchant adventurers who made the Empire. The methods were the methods of the wonder-makers of science, who put into facts and figures the discoveries and revelations of the master-minds of the world, and who were yoking the forces of nature to the service of man.

Sir John F. L. Brunner, replying, said that it used to be a reproach that science was not applied to industry. Formerly the head of a business hesitated to engage a highly trained chemist because he would not have known what to do with him. To-day the heads of businesses were better equipped and they knew what use to make of chemists. What the industrialist wanted mostly was knowledge which he could turn to pounds, shillings and pence. Science and industry must co-operate; science must help industry, and as an industrialist he would say that industry must help science. He hoped that companies able to do so would endow research, for the Universities to-day were in great need of money to carry on their research work.

To the health of the guests, submitted by Sir W. J. Pope, the Very Rev. W. R. Inge, Dean of St. Paul's, and Lord Justice Sargant replied.

SOCIETY OF PUBLIC ANALYSTS

A meeting was held in the Chemical Society's Rooms in Burlington House, on December 5, Mr. P. A. Ellis Richards presiding, and four papers were read.

Mr. H. Toms, M.Sc., presented an account of "The Crystalline Bromides of Linseed Oil." The "insoluble bromide" of linseed oil, first described by Hehner and Mitchell, appears to consist of mixtures in varying proportions of two crystalline bromides, viz., (1) a linolic-dilinolenic bromo-glyceride, and (2) the trilinolic bromo-glyceride of the oleic-linolic-linolenic bromo-glyceride. These two bromo-glycerides have been obtained in pure condition by crystallisation from ethyl acetate, and melt at 153° C. (corr.) and 117° C. (corr.), respectively. The solubility of the more insoluble bromide in ethyl acetate lies between 0·15 and 0·20 g. per 100 c.c. at 15° to 20° C. The methods of estimating the bromine in these compounds have been studied, and it is shown that theoretical results can be obtained by the method of Carius and by a modification of the method of Stephanow, but not by the lime method. Various methods of estimating the more insoluble crystalline bromides are described, the yields of the purest product from different oils varying from 9·39 to 11·6 per cent. The results obtained suggest that there is some relationship between the yield of this crystalline bromide and the iodine value of the original oil.

A "Plea for Standardisation," was put forward by Mr. M. S. Salamon, B.Sc., who emphasised the fact that in every field of analytical chemistry it was common to find different, although well-recognised methods of analysis yielding varying results. Particularly was this so with dried milks; in one instance a sample of dried milk was sent to four well-known analysts and a considerable divergence of figures resulted according to the methods used, particularly in the estimations of the fat and lactose. In the examination of essential oils, the need for standardisation was urgent, for in many cases minute modifications in detail cause quite substantial differences in results. This was true of inorganic materials of simpler composition, and the author sees a recognition of the difficulties in the details laid down for analyses under the Fertilisers and Feeding Stuffs Act. He strongly advocates the formation of a Committee to consider the whole question.

"A Note on the Estimation of Chromium" was read by Hubert T. S. Britton, M.Sc. The gravimetric methods of estimating chromium as oxide are discussed. Whatever precautions are taken to use only the purest reagents and salts, and platinum crucibles, the ignited oxide always contains some chromate. Hence, such methods give results that are too high. It has been found that chromium can be quickly and accurately estimated volumetrically, by adding to an approximately neutral solution of a chromium salt an excess of sodium peroxide (about 1 g.) and boiling for ten minutes to complete the oxidation to chromate and to decompose the unused peroxide. After acidification with either sulphuric or hydrochloric acid, excess of potassium iodide is added and the liberated iodine is then titrated in the usual way.

Mr. R. L. Andrew described "The Colorimetric Estimation of Lead in Cream of Tartar." During 1921-22 all imports of cream of tartar into New Zealand were examined for lead, and the following method was found to give similar results and to be less cumbersome than the B.P. method. One c.c. of 5 per cent. potassium cyanide solution, 1 c.c. of ammonia solution, and 40 c.c. of water are added to 2 grams of cream of tartar, and solution effected by warming and shaking. After cooling and filtering, any tint is matched in the standards by the addition of very dilute caramel. These standards are prepared in a similar way from 2 grams of lead-free cream of tartar, with the addition of requisite amounts of lead nitrate solution containing 0·01 per cent. of lead. A few drops of 10 per cent. sodium sulphide solution are added and the amount of lead estimated by comparison. If a standard water solution of lead is used a serious error is introduced as the colour is only about half the depth of that produced with a tartrate solution.

CHEMICAL SOCIETY

The President, Prof. W. P. Wynne, F.R.S., occupied the chair at an ordinary meeting held on Thursday, December 6, 1923, at 8 p.m.

The following considerations were put forward by the author :—

The additive formation of four-membered rings. Part III. A system of nomenclature for heterocyclic four-membered rings, and the formation and properties of some derivatives of β-methylene di-imineoxide. C. K. Ingold.

It has been found that the formation of a four-membered ring by the additive union of double bonds (I) is of considerable generality. This confirms the prediction (Part I), made from the analogy with the tautomeric change or internal addition reaction, shown in (II). The variety of new heterocyclic ring-types which have already been produced from the five types of double bond studied (C : C, C : N, C : O, N : N, N : O), is such as to call for a definite scheme for the nomenclature of these compounds. A proposal is made to meet this need. Part of the object of these investigations is to discover which types of four-membered heterocyclic ring are the most stable, in order to learn which of the aromatic heterocylic rings are most likely to possess stable bridged phases. The production of an unusually stable type of four-membered ring is of interest from this point of view. Now, it has been shown in Part II that azomethines of a certain type tend to pass into stable bimerides containing the ring (III). Moreover, there is evidence, confirmed by recent experiments, that many nitroso-compounds pass into stable bimerides containing the ring (IV). Hence, if an azomethine and a nitroso-compound of the types referred to be placed together, they should unite giving either the ring (V), or the ring (VI). Experiment shows that the ring obtained in this way has the structure (V) and not (VI), and that it is quite stable at ordinary temperatures. Its constitution has been established by alternative synthesis, and by a study of its decomposition at a higher temperature.

VI

Dr. H. J. S. Sand gave an account of

The dependence of polarisation-overvoltage on hydroxyl and hydrogen ion concentration. Part I. Polarisation-overvoltage of an antimony cathode in aqueous alkaline solution. H. J. S. Sand and E. J. Weeks.

The overvoltage, ω, of an antimony cathode in alkaline solution, determined by the commutator-method as previously described, has been found to obey to a very considerable degree of accuracy the empirical equation : $\omega = a - 2h$, in which h—briefly referred to as p_H voltage—is the potential difference between a standard (calomel) electrode and a hydrogen electrode in the solution examined, and a is a constant depending only on the temperature. This result, as well as the spontaneous formation of gas-bubbles, may be explained by the assumption that an ion $H(OH)_2''$ exists which has a definite supersolubility limit. When a sufficient number of these ions have assembled in the solid (or liquid) state to produce the energy necessary for the formation of a gas-bubble, they decompose simultaneously (explode). The conclusion has been drawn that the identical overvoltage-p_H voltage relation should be found with other metals which act as indifferent cathodes in alkaline solution.

A paper communicated by Dr. H. King is summarised as follows:—

Stereoisomerism and local anæsthetic action in the β-eucaine group. Resolution of β- and iso-β-eucaine. Harold King.

α- and β-vinyldiacetonalkamines on benzoylation yield O-benzoyl derivatives. Benzoyl α-vinyldiacetonalkamine is known commercially as the local anæsthetic β-eucaine, whilst for convenience it is proposed to call benzoyl β-vinyldiacetonalkamine, iso-β-eucaine. These two bases have been resolved by camphorsulphonic and bromocamphorsulphonic acid respectively. Each resolution presents some novel aspects, that of β-eucaine being effected within the transition interval where the partial racemate dl-β-eucaine d-camphorsulphonate is the most stable form, whilst in the case of iso-β-eucaine the salts being of approximate equal solubility separate alternately from the solution on fractional crystallisation. The circuit of reactions detailed in this investigation is summarised in the following diagram.

$$\begin{tikzcd}
& \text{Vinyldiacetonamine} \arrow[dl] \arrow[dr] & \\
\alpha\text{-Vinyldiacetonamine} \arrow[d] & & \beta\text{-Vinyldiacetonamine} \arrow[d] \\
\text{Benzoyl } \alpha\text{-Vinyldiacetonalkamine} \arrow[d] & & \text{Benzoyl } \beta\text{-Vinyldiacetonalkamine} \arrow[d] \\
\text{d-}\beta\text{-Eucaine} \arrow[d] & & \text{l-iso-}\beta\text{-Eucaine} \arrow[d] \\
\text{d-}\alpha\text{-Vinyldiacetonalkamine} & & \text{d-}\beta\text{-Vinyldiacetonalkamine.}
\end{tikzcd}$$

The relative local anæsthetic actions of β-eucaine, iso-β-eucaine, and the optically active forms are recorded.

In reply to Dr. G. W. Clough, Dr. King said that the physiological action is independent of the acid with which the base is combined, since hydrolysis takes place when the substance penetrates into the tissues.

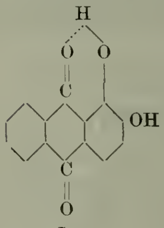
The following paper was read by the author:—

β-Alizarin. An isomeric form of alizarin. Albert Green.

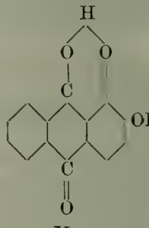
When alizarin is boiled with thionyl chloride to complete solution, and the solvent is evaporated, a light brown solid (m.p. 164–170°) is formed. On immediate recrystallisation from glacial acetic acid and then from benzene or alcohol this yields golden yellow needles melting at 195–7° (uncorr.). The light brown solid fumes on standing in air, owing to decomposition of adhering thionyl chloride, and yields alizarin.

Analyses and molecular weight determinations of the yellow substance yield the formula $C_{14}H_8O_4$. This substance, termed β-alizarin by the author, appears to be stable under ordinary conditions, but is converted into alizarin by boiling with alcoholic solutions of hydrogen chloride, hydrogen bromide or hydroxylamine hydrochloride. The same result is obtained by pouring its solution in concentrated sulphuric acid into water or anhydrous ether, or by acidifying its solution in aqueous sodium hydroxide. On bromination it gives 3.bromo-1.2.-dihydroxy anthraquinone (as does alizarin). On boiling for six hours with acetic anhydride β-alizarin gives pure diacetyl alizarin. Alizarin gave an impure product after 16 hours boiling. β-alizarin is 15 times more soluble at 13° C. in benzene than alizarin. Attempts to isolate intermediate compounds of alizarin and thionyl chloride were fruitless. It is well known that I.hydroxy anthraquinones are alkylated only with much difficulty, while the ethers of 2.hydroxyanthraquinones are easily prepared. This fact has led to the suggestion that the former compounds may have an *o*-quinonoid structure. The easy formation of diacetyl alizarin from β-alizarin is suggested tentatively as evidence of different structures for the two forms, but no definite statement is advanced pending the completion of further work.

Dr. G. W. Clough said that all ten of the dihydroxy-derivatives of anthraquinone which were apparently theoretically possible were known, and their structures had been determined. He referred to the views of Pfeiffer, Dimroth (I), Georgievics (II) and Watson on the structure of alizarin and other hydroxyanthraquinones, and suggested that a comparison of the absorption spectrum of "β-alizarin" in alcoholic solution with the absorption spectra of other hydroxyanthraquinones in the same solvent might give some indication of the structure of the reported new compound. The theoretical and practical importance of Mr. Green's observations made it desirable to extend the investigation to similar compounds, especially to the two mono-hydroxyanthraquinones. He asked whether pure thionyl chloride was used, since the technical product sometimes contains tin, yielding a tin compound with alizarin.

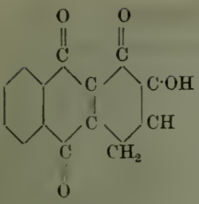


I

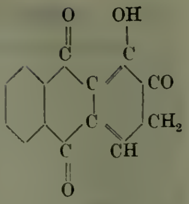


II

Dr. C. K. Ingold suggested, as a simpler working hypothesis than any previously mentioned, that one of the alizarins might be a ketonic individual, such as (III) or (IV). The two alizarins would then be tautomeric bodies,



III



IV

stable enough, however, to require a reagent for their interconversion, as is the case with anthranol and anthrone (the analogue of III).

Mr. Green replied that the thionyl chloride used was the "pure" quality, and was redistilled immediately before use. Isomeric forms of three further hydroxyanthraquinones had been obtained. The peroxide structure for the two carbonyl oxygens seemed to be indicated for the new isomers, for certain regularities had appeared in their properties.

Work on the oximes was described by Dr. O. L. Brady:—

The isomerism of the oximes. Part XV. The supposed fourth benzildioxime. O. L. Brady and F. P. Dunn.

The authors have repeated the work of Atack and Whinyates (*T.*, 1921, **119**, 1184), but have failed to obtain any evidence of the existence of a fourth benzildioxime. Some of the principal objections to a purely structural theory of the isomerism of the oximes as suggested by Atack (*ibid.*, 1175) are brought forward, particularly the existence of two O-ethers.

Taking a freshly-prepared solution of 1 gram of α-benzildioxime in 40 c.c. of $2N$-sodium hydroxide, and a similar solution which had been kept for three hours, the speaker demonstrated that on the addition of an equal volume of a 2·5 per cent. solution of nickel chloride and a little ammonia the colour of the precipitate was the same in each case. In the presence of alcohol both gave a much darker red precipitate. He pointed out that Atack and Whinyates had apparently used alcohol to "stabilise the α-form," and suggested that an explanation might be found in this fact, although the low melting-point remained unexplained.

The President, after complimenting the authors on having removed a compound from the voluminous literature of organic chemistry, said that unless Dr. Atack and Mr. Whinyates could substantiate their challenge, the authors' view of the matter would meet with acceptance.

Mr. W. E. Garner then gave an account of the following work:—

The alternation in the heats of crystallisation of the normal monobasic fatty acids. W. E. Garner and F. C. Randall.

Measurements of the heat of crystallisation of lauric, undecoic, capric, nonoic, and caprylic acids have been made and the following values obtained:—lauric, 43·73; undecoic, 32·20; capric, 38·86; nonoic, 30·54; caprylic, 35·44 cal/gm. The heat of crystallisation of an odd acid is lower than the mean for its neighbours in the series, and the heat of crystallisation curve resembles the melting point curve for these acids. The molar specific heats of the acids in the liquid state also show alternation, but this is very slight; the odd members possess the higher value. These results throw light on the causes of alternation in the physical properties of organic substances with long chains.

The odd acids, undecoic and nonoic, crystallise in two enantiotropic forms, α and β, and the heats of transition of these have been measured and found to be 9·89 and 8·39 cal/gm. respectively. The heats of crystallisation of the β-forms of the odd acids lie slightly above the curve for the even acids, thus giving an example of inverse alternation. The results are in agreement with the view that the even acids are more closely related to the β than to the α forms of the odd acids. The bearing of this on the work of Müller and Shearer on the length of the carbon chains in these acids is discussed, and it is concluded that the differences between the heats of crystallisation of the higher members of the odd and even acids may be ascribed to differences in the mode of attachment of the carboxyl groups in the crystal molecule.

Prof. F. G. Donnan, F.R.S., remarking on the laborious nature of the interesting research, agreed that the explanation given was the best.

Dr. R. H. Pickard, F.R.S., having questioned the legitimacy of a comparison of the curves with those derived from optical measurements in solution, Mr. Garner agreed, explaining that he had used the latter merely in the course of illustration of the views of Sir W. H. Bragg on the nature of the carbon chain.

BRITISH LEATHER MANUFACTURERS' RESEARCH ASSOCIATION

The fourth annual general meeting was held on November 29, under the presidency of Mr. J. A. Janson, Worshipful Master of the Leathersellers' Company. After the business meeting, a lecture was given in the Livery Hall of the Leathersellers' Company, by Dr. R. H. Pickard, F.R.S., director of research to the Association.

Dr. Pickard explained that the policy of attacking fundamental principles had been continued, and he felt confident that they could best assist the trade by devoting their attention to work of this kind. He then discussed the work which had occupied the staff during the past year. The difficulty experienced in soaking back dried, and more particularly sundried hides and skins had been shown to be due to the coagulation of their albumen constituents by the action of heat and light. Application for a patent had been filed provisionally protecting the use of certain salts, which when added to the soak liquors even in very small quantities, had the effect of dispersing these coagulated albumens. Experiments were shown illustrating the rapidity with which skins so treated could be soaked back. In the account of recent work on the formation of "spue" on chrome leather, Dr. Pickard said that the grease originally present in the skins did not seem to be the cause of this defect.

This part of the work was illustrated by a series of microscope slides projected on to the screen. The various fats and greases were stained by selective stains and their fate throughout the various stages of manufacture had thus been traced. On the much discussed subject of "acidity" or "free sulphuric acid" as a cause of deterioration of sole leather, bookbindings, etc., the present state of knowledge was very unsatisfactory. Existing tests such as the Proctor-Searle method and the indicator test recently put forward by the Boot and Shoe Research Association frequently gave misleading results. The subject was being examined thoroughly but the problem was not yet solved.

A series of lantern slides was exhibited, showing sections of defective leathers. This work was being done in order to interpret in scientific terms defects recognised in the trade under the names of tinniness, stretchyness, lack of tensile strength, etc., and to attempt to trace their causes. Many experiments on the formation of sludge in vegetable tan pits were in progress. The work had mostly been devoted to the possible methods of preventing the formation of this sludge by heating, various additions, and blending of materials. Work had also been commenced on the possibility of utilising sludge already formed, and on the effects of moulds and other micro-organisms and their products in the formation of sludge. In conclusion Dr. Pickard thanked those members of the Association who had supplied the staff with a large amount of information and material.

Mr. E. D. Evans, President of the United Tanners' Federation, in proposing a vote of thanks, expressed his appreciation of the lecture and emphasised the utility and great promise of the work of the Association.

On the occasion of its opening meeting, the University of Paris conferred the diploma of Doctor *honoris causa* on Prof. J. J. Thomson, F.R.S., Svante Arrhénius, Señor Torres y Quevedo (Spain), Prof. Golgi (Italy), and Prof. Keen (Philadelphia, U.S.A.).

CORRESPONDENCE

THE THEORY OF CATALYSIS

Sir,—In a paper on "Heterogeneous Gas Reactions" in the November number of the *Journal of the Chemical Society*, Messrs. Hinshelwood and Pritchard develop a theory of catalysis in which the action of a surface in promoting the decomposition of a molecule A B adsorbed on it is attributed to the fixation of the part A, say, on the surface, leaving the part B in a situation in which it can be drawn away from A, the latter being incapable of following B in its course. I have always understood that some such idea was implied in Mercer's theory of catalysis, put forward in 1842, although the explanation (which seems very similar to the one above) given on p. 225 of my "Text-book of Inorganic Chemistry" may be a slight modification of Mercer's theory. I have usually pointed out, as an analogy, that it is difficult for either one of two dogs to divide a rat which he is holding between his teeth, but that the two dogs together can do it easily. This is hardly even "a mechanical picture," but it may please those to whom the "passage of an electron to an orbit of higher quantum number," to quote the two authors mentioned, may not seem very closely related to the phenomena of catalysis.—I am, Sir, etc.,

J. R. Partington

East London College,
University of London

SOURCES OF OIL CAKES

Sir,—I should be very much obliged if any of the readers of the *Journal* could indicate to me a probable source for obtaining some of the undermentioned cakes or meals, which I require for some important research work :—

Beechmast cake
Candlenut ,,
Madia ,,
Safflower ,,
Sunflower ,,
Camelina cake
Hempseed ,,
Olive ,,
Sesame ,,
Poppyseed ,,

Preferably both decorticated and undecorticated.—I am, Sir, etc.,

W. Leslie Carter

Birmingham
December 7, 1923

BRITISH DYESTUFFS INDUSTRY

Sir,—The letter from the Clayton Aniline Company in your issue of December 7 shows that they still labour under the misapprehension that I was responsible for the price of 12s. 3d. for Sky Blue F.F., mentioned in my letter in your issue of September 21.

The price of 12s. 3d. was quoted by Prof. Morgan on page 872 of your issue of September 14, and the Clayton Aniline Company are in error in attributing that price to me and treating it, as if it was the current market price at the date of my letter.

May I therefore briefly state the following:
(1) I said the price of 12s. 3d. for Sky Blue F.F. is 12 times its pre-war price. This is true.

(2) I said that the Sky Blue, marketed by the Clayton Aniline Company was weaker than Chlorazol Sky Blue F.F., and therefore its price must necessarily be a lower one. This statement is true.

(3) In neither of my letters did I question the quality of the Sky Blue made by the Clayton Aniline Company. The best assurance that I can give them on this point, is the fact that I use their product in my dye-house, the supply being obtained through one of their associated firms.—I am, Sir, etc., C. M. Whittaker

Cheadle Hulme, Cheshire
December 8, 1923

THE DECAY OF BUILDING STONE

Sir,—The short report (*Chemistry and Industry*, page 1185) of the communication on "Decay of Building Stones" made by Mr. Harrison and myself to the London Section of the Society is not quite correct in one or two particulars.

The statement attributed to us that nitrifying organisms could not resist "sulphur" in the air is rather startling, since we have no information of value on this subject. The point we endeavoured to make was that any action due to nitric acid in the air, or to nitrifying organisms present in stone, is of altogether secondary importance in towns, particularly London.

We did not condemn all stone preservatives as ineffective, nor are we in a position to make a sweeping statement of this character. In the absence of large scale tests, or of data collected over a long period from exposure tests, it is not possible to pass such a judgment on preservatives generally. All that can safely be said at present is that some stone preservatives may prove an advantage when used carefully for small structures. The application of preservatives to large and elaborate structures which are difficult of access is not, in our view, likely to be of great value in the long run, partly because of the difficulty of renewing treatment.—I am, Sir, etc.,

London J. J. Fox
December 11, 1923

THE DIFFICULT ENGLISH

M. the Editor,—I like you so very much that you have study the examination questions: I have suffer so badly from them. Will you not say us, however: "Is the letters-man not as bad as the chemistry-man, when he ask questions of the poor schools boy?"

Also I like what the Reviewer say of the "molality" and other beautiful* nonsense words in the Thermodynamics of the MM. Lewis and Randall. Truly, I think, they write not the English "in the ordinary sense of the term." Perhaps now he have built the Sky Scrapaire, the—as I have call him—cacologophilic† American will be in a hurry to make him fast ready for a Tower of Babel of the Sciences, which shall be the much biggest thing in the New World—so as to put in all the bad English, whom you shall emigrate. What a beautiful land you then will have—one where the English is once again the spoken. This shall be, I think, the end of your difficulty of the unemployment and the over-population and the cause of the return of the Dr. Marie Stopes to the coal and the stones animals.

The Mr. Reviewer disappoint me a little, I must say me, in his words. Should he not himself be more careful, when he write his so clever notices of the books, and live him up to the Oxford where he was a student, I suppose me? Perhaps, he even have browse with the Prof. Gardner, and wish to show him how much he have profit from the classics. He say: "The phraseology employed by the authors occasionally pulls the reader up with a jerk." I have a friend who draws the picture to laugh. I ask him to do me one of "a phraseology pulling up a reader," which I can send you. You will perhaps have pictures like *The Times*—but, please, no Brides or of the Sport. As the Mr. Smithells so truly say, "such language is positively dangerous." "Phraseology employed" belong to the Gibbs' Rule of Phrases, I suppose. When you instead say the short English "words used," it seem to me so nicer. The English small words are much so nicer and also so saving of the space and of the tongue—and of the temper of the reader, who read him with care.

I have speak before of Anatole France. He say it cost him twenty years' work to write the Jeanne D'Arc. It is tell us:—

"He multiplied the corrections, interpolated phrases, arranged fresh transitions, cut up his sheets until they resembled a puzzle, put at the beginning what was at the end, at the top what was at the bottom and fixed the whole together with the gum brush."

"He suspected that the work, written without leaning towards one point of view or another, with sole respect for the truth, would satisfy but few readers."

Is it not so? This is the way to write of the science! A critic say him, he show deep scientific knowledge of Astronomy and ask him the sources of it. He say, he consulted only a book for the little child, but he add:—

"The important thing is not, perhaps, my scientific baggage, which is light, but rather the reaction of modern discoveries upon a sensibility formed by long commerce with the gentle, subtle and human authors of our country."

---

* Perhaps I say better "activated" nonsense, of the kind of the nitrogen or out-blown charcoal.

† I see the English call the compound of the M. Bunsen cacodyl, not kakodyl.

Pointing to his library, he then say :—

"There are my sources. You will find there nothing save great or charming writers who spoke good French—that is to say, who thought clearly. For one cannot exist without the other."

Is not this a beautiful thought—and true ? Also—to remember ? How can the young man learn well, when he have so bad examples before him to read ? You shall help him much.

Like the Mr. Gosse, of *the Times Sunday*, I am tired and now take me a holiday for the travel. I have not the good enough adjectives for you, so shall sign me only, this last time,

December 10 Parisian

A QUERY

Sir,—In an out-of-the-way place like this one finds it very difficult to obtain information that would need only a few seconds' reference to some up-to-date chemical dictionary. There are two very ordinary substances that are repeatedly referred to in articles and advertisements, but no one ever dreams of assisting unfortunate people like myself by explaining what they are: I mean "lithopone" and "blue water gas." If you or any kind reader would kindly devote a minute or two to a brief explanation I should be greatly obliged.—I am, Sir, etc., E. G. Bryant

Priska, South Africa,
November 19, 1923

[Lithopone is a pigment consisting of a mixture of zinc oxide, zinc carbonate, zinc sulphide and barium sulphate, and is made by heating the mixture of zinc sulphide and barium sulphate obtained by mixing solutions of barium sulphide and zinc sulphate. Blue water gas is the term applied to the unenriched mixture of hydrogen and oxides of carbon formed when steam is passed through incandescent carbon.]

NEWS AND NOTES

FRANCE

Pasteur Day and the Laboratories

It is announced that the sum collected for the benefit of French scientific laboratories on "Pasteur Day" amounted to 13 million francs, or over £160,000.

CANADA

Crude Petroleum in 1922

The production of crude petroleum in Canada in 1922 amounted to 179,068 barrels having a sales value of $520,073, plus Government bounties on these sales amounting to $91,103. In 1921 the production was 187,541 barrels, having a total value of $641,533. The average market value per barrel in 1922 was $2·90 compared with $2·92 in 1921.

Cobalt

Canadian production of cobalt in 1922 was 569,960 lb. valued at $1,852,370, the price per lb. being $3·25. For the last 20 years the major portion of the world's supply of cobalt has been derived from the silver-cobalt-nickel arsenides of the Cobalt district.

Altogether 3719 tons of cobalt ores and residues were treated, the content of metallic cobalt being (by assay) 536,400 lb. The following is a summary of the statistics for 1922 :—

	Output of smelters		Marketed	
	Total lb.	Cobalt contained lb.	Quantity lb.	Value reported by smelters $
Metallic cobalt	106,274	106,274	109,067	282,602
Cobalt oxide . .	360,495	252,347	398,697	798,271
Mixed oxide . .	86,730	39,023	123,605	99,687
Residues exported . .	†	172,311	1,036,000	*156,402
Quantity		569,960	—	1,336,962

* Estimated. † Not given.

BRITISH INDIA

First Groundnut Forecast, 1923-24

A memorandum based on reports received from the three provinces of Madras, Burma and Bombay, which comprise 99 per cent. of the entire groundnut area of British India, states that the total area sown in the present season in these provinces is estimated at 1,687,000 acres, as against 1,855,000 acres (revised) at this time last year, or a decrease of 9 per cent. In Madras the crop has generally been benefited by the September rains, and sowings are proceeding briskly, and in both Burma and Bombay the present prospects are satisfactory.—(*Ind. Tr. J., Oct.* 25, 1923.)

GENERAL

Mauritius in 1922

According to the Annual Report of the Department of Agriculture the sugar crop for the 1922–23 season is estimated at 233,500 metric tons (197,420 t., in 1921–22), about 6 per cent. below the normal output. Approximately 97 per cent. of the crop will consist of Vesou sugar; there will be very little first syrup, and 3 per cent. of low syrup. At present 52 sugar factories are at work, and 174,000 acres are under the crop. The production of alcohol in 1921–22 decreased to 1,749,994 litres, and a further decrease is expected, owing to the new licensing law. A large distillery has been erected for the production of power alcohol of the "Natalite" type. Nothing new is reported of the subsidiary agricultural industries, viz., aloe fibre, coconuts, and vanilla, but experimental work on crops and livestock is being actively continued by the Department.

REVIEWS

TREATISE ON GENERAL AND INDUSTRIAL ORGANIC CHEMISTRY. *By* DR. ETTORE MOLINARI. *Translated from the third (enlarged and revised) Italian edition by* T. H. POPE, B.Sc. *Part II. Pp. viii*+457-897. *London: J. and A. Churchill*, 1923. *Price* 30*s. net.*

The translation of this well-known work has been done in an excellent manner. The division of the organic section into two parts is convenient. In certain parts there are considerable additions to the descriptions of technical operations which appeared in the first English edition. The statistics have been brought up to 1913, and in a few cases only to 1920. The numerous illustrations are mostly of machines made in Germany, and naturally the technical operations described are those in continental practice. The revision of the second Italian edition was probably undertaken too soon after the war for a full description of the great development of many industrial processes which then occurred to find a place.

The work as a whole, and the section of it now under review in particular, seems to be suitable for the student of pure chemistry requiring some information on industrial applications, and for the industrialist who requires a short description of substances allied in properties to those he is using. This section of the work, however, does not appear suitable for the systematic study of that part of organic chemistry to which it deals, either on the pure or applied side.

ROBERT H. PICKARD

ORGANIC CHEMISTRY FOR ADVANCED STUDENTS. PART III. SYNTHESIS. *By* JULIUS B. COHEN, B.Sc., Ph.D., F.R.S. *Fourth Edition. Pp. vi*+412. *London: Edward Arnold and Co.*, 1923. *Price* 18*s.*

The third volume has appeared with commendable rapidity after the first and the second, and is in every way up to the standard set by its predecessors. Amongst the new matter will be found references to the recent work of Ruzička on the terpenes and allied substances, and although in this section the author brings out the more salient facts and gives a fair and concise description of the views held by Meerwein and others, yet in certain cases he exercises a kind of diffidence which does not seem altogether to be warranted by the experimental data. For example, he says (page 242): "Carene . . . is said to occur in Indian Turpentine . . . and has probably the formula . . . " Surely there can be no question that Simonsen isolated Carene from *Pinus longifolia* and that its formula is beyond doubt? The relationship between Pinene and Carene and their connexion with what ought, in the *para* series, to be camphene, but is not, afford a wonderful natural picture which the author has somehow failed to paint effectively. The recent work of Pyman on the glyoxalines and of W. H. Perkin, Robinson and others on the alkaloids is given in detail, the accounts of the work on cryptopine, strychnine and brucine being especially clear and concise. In fact, the whole of the section on the alkaloids is written in a manner which will render it capable of being readily understood by the student. In connexion with the synthesis of camphoric acid (p. 262) it is perhaps desirable to point out that the reference to the 1906 paper of Perkin and Thorpe is misleading. This paper merely confirmed the work described in a previous communication published in 1904, the abstract of which was published in the *Proceedings* of the Chemical Society in 1903, actually prior to the appearance of Komppa's paper in the *Berichte*. It is perhaps unfortunate that the author has refrained from giving any account of the colouring matter of flowers, but refers the student to the well-known monograph by A. G. Perkin and Everest. A brief description would give the reader some idea of these important substances and would lead him to make further enquiries elsewhere. In conclusion it is suggested that in future editions the name index should contain references to each individual author, with cross-references where joint work is concerned. It is not always the author whose name appears first who is primarily responsible for the work.

JOCELYN THORPE

THE MANUFACTURE OF NITRIC ACID AND NITRATES. *By* ALLIN COTTRELL, M. Sc. VOL. VI. THE MANUFACTURE OF ACIDS AND ALKALIS. *By* DR. G. LUNGE, PH.D. *Completely revised and re-written under the editorship of A. C. Cumming, O.B.E. Pp. xv*+454. *London: Gurney & Jackson*, 1923. *Price* 36*s.*

In this volume the author has succeeded in compiling a valuable and instructive account of the pot process for the manufacture of nitric acid. The matter is arranged systematically and the facts stated with a commendable brevity, which makes the book particularly useful to the technical chemist, a great mass of information being condensed into a relatively small space, whilst clarity is maintained by very numerous sub-headings.

The title of the volume is not, perhaps, very well chosen, since only the pot process receives detailed consideration. The section on nitrates is, for the same reason, quite inadequate from the point of view of technical information.

So far as the general arrangement of the book is concerned, only praise can be offered, with the single exception of the sections on analytical methods, which might with advantage be collected into one chapter.

The sections on denitration and the concentration of dilute nitric acid are rather disappointing and stand in great contrast to the other sections of the book. Such an important question as the technical utilisation of dilute nitric acid, for example, is hardly discussed, and the chemical engineering problems connected with this and other phases of the process are not dealt with at all.

The author has added considerably to the value of the book by quoting verbatim original descriptions, reports, etc., but in some cases the change from the ordinary text to the special headings of a factory research report is apt to be confusing unless there is some preliminary description of the size, type and operating conditions of the plant with which the report deals.

The experience gained of large-scale practice during the recent European war rightly occupies an important place throughout the book, but its value would have been enhanced if accompanied by a fuller discussion of the theoretical principles underlying the use of a particular type of plant or modification of a process.

The misprints in the text are exceptionally few and the illustrations admirable. A few cases of undesirable repetition occur, however, but these are minor details which do not detract from the general value of the book.

There is rather an obvious misstatement concerning the Bowman and Scott method for nitric-acid estimation. The author states quite rightly that the method gives only the real nitric acid, but then goes on to say that the results are hence identical with those obtained by the nitrometer method, which, of course, is incorrect. Other minor errors concern the oxidation of nitrous acid in the Pohle air lift, and the titanium sulphate method for the nitrogen acids in nitre cake. These, however, are small errors almost inevitable in a work covering so much ground.

The book should not only maintain, but very much increase, the popularity enjoyed by the earlier editions of Lunge's treatise, and the author must certainly be congratulated on the able manner in which he has created a new and up-to-date account of the process, whilst maintaining the valuable and practical view-point of the former work. H. W. Webb

The Cultivation of the Sugar Cane in Java. An elementary treatise on the agriculture of the sugar cane in Java and more especially on its cultivation on the Krian Sugar Estate. *By* R. A. Quintus. *Pp. xi*+164. *London: Norman Rodger*, 1923. *Price* 12*s*.

In the former of the two parts comprising this book the author treats of the chemistry, physics and bacteriology of the soil with special reference to the conditions that obtain in Java, and then describes the morphology and physiology of the sugar-cane plant and the various diseases to which the plant is liable. The second part of the book is chiefly devoted to the conditions and methods of cultivation of the cane in Java.

The author's style is frequently marred by a carelessness in phraseology which sometimes obscures his meaning, there is needless repetition in some places, and words are occasionally used in a wrong sense. On p. 18 it is stated that "Ammonia is the most powerful base," and the reader is left to infer from the context that what is meant is that ammonia is more readily adsorbed than other bases by colloids. Expressions such as "not too brief a moment," "decrease of growth," and "a short time longer," though not misleading are certainly irritating. Chemical equations are referred to as formulæ, the words "adsorb" and "absorb" are used to describe one and the same phenomenon, and "maximum water-capacity" is used (p. 27) where "maximum water-content" is intended. These are but a few instances of many.

The subject of colloids and their bearing on the texture and fertility of soils is especially important in Java, where rice forms one of the crops in rotation with cane; this subject is dealt with in some detail and useful practical information on the treatment of Javanese soils is given. With regard to the bacterial flora of soils, the author adheres to Russell and Hutchinson's hypothesis of the inimical effect of soil protozoa on the bacteria; he makes the surprising statement, however, that the spores of bacteria are not destroyed in this way (p. 29), thus wrongly ascribing to the protozoa the selective action that partial sterilisation by heat or antiseptics is believed to effect. Cane diseases and their remedies are described adequately and well, though the author makes a curious double slip in connexion with *sereh* disease (p. 69). After stating that the disease is hereditary, so that selection is of no use. he observes in the next sentence that this (*i.e.*, selection) is the only means of combating the disease, and in the next paragraph he gives another method of combating the disease by crossing improved varieties with others that are immune from *sereh*.

Apart from the faulty phraseology previously referred to, the second part of the book is very good and should prove a useful guide, especially to the Javan planter. The author is obviously thoroughly conversant with the practical details of cane cultivation in Java; he gives an excellent account of the complicated system of irrigation and drainage and of the treatment of the soil before and during the growth of the crop. and has supplemented the textual description with nearly forty excellent plates besides other illustrations. The book concludes with some useful statistics concerning the Javan sugar industry.

Lewis Eynon

REPORT

Report on the Industrial and Economic Situation of China in June, 1923. *By* H. J. Brett, *Commercial Secretary, Shanghai. Together with a Report on the Trade of Chinese Turkestan, by* C. P. Skrine, *H.M. Consul-General, Kashgar. Department of Overseas Trade. Pp.* 52. *H.M. Stationery Office,* 1923. *Price* 1s. 6*d.*

The conditions of lawlessness and brigandage previously recorded (*cf. Chem. and Ind.*, 1923, 107) still continue, with adverse effects on trade.

The industrial development of the country progresses in spite of adverse conditions, and there are now few industries not represented in China. Many concerns run without foreign aid are, however, feeling ill-effects from under-capitalisation, absence of reserves, and inefficient management. Few mining developments have taken place recently. Coal output remains at about 20,000,000 t. per annum, the export in 1922 being 1,886,398 t.

The net value of trade in 1922 was a record, amounting to 1600 million taels (the value of the tael was about 3s. 9d. during 1922). Imports were valued at tls. 945 mill. and exports at tls. 655 mill. Imports of dyestuffs, colours, and paints were valued at tls. 24·8 mill. Germany is making progress in the recovery of her pre-war trade. There has been a slight increase in China's total trade with Britain, though actually imports into China have decreased. Traders of all nationalities have had to face great difficulties lately, but it is satisfactory to note that Great Britain's share is being maintained.

COMPANY NEWS

CASSEL CYANIDE CO., LTD.

The net profit for the year ended September 30, 1923, including the balance from last year, amounts to £67,388, and deducting the interim dividend of 3d. per share paid in June, £49,763 remains for distribution. A final dividend of 6d. per share, totalling £35,250, is to be paid, and £14,513 carried forward. The issued capital of the company is £352,500, in 5s. shares.

BRIMSDOWN LEAD CO., LTD.

The annual general meeting will be held at the Great Eastern Hotel, E.C. 2, on December 21, at 2.30. In the circular announcing the meeting it is stated that the negotiations for amalgamation with other important firms carrying on similar business have recently made further progress, and that the directors consider it would be inadvisable that there should be a public discussion of the company's affairs until they are in a position to submit a definite proposition for the shareholders' consideration.

BRITISH OXYGEN CO., LTD.

An interim dividend of 9d. per share, tax free, has been declared.

SCOTTISH OILS, LTD.

Owing to the depression in the oil trade, and pending the result of the full year's working, the directors announce they are unable to recommend payment of the dividend in January on the 7 per cent. non-cumulative participating preference shares.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Dec.* 6)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Aluminium, chemicals, oils, colours, tanners' supplies ..	600
,, ..	Skins, casein ..	601, 602
Chile ..	Earthenware ..	627
Italy ..	Pig tin	613
Japan ..	Drugs, chemicals ..	11490/85/F.E./C.C./2
Netherlands	Rubber	617
Norway ..	Lead sheets and tubes	618
Smyrna ..	Paper, photographic apparatus	624
South Africa	Iron piping (tender)	12696/E.D./E.C./2
Switzerland	Iron, brass, copper and bronze wire, rubber tubing ..	21192/F.W./E.C./2
United States	Leather	21158/F.W./M.C./2

TARIFF CUSTOMS EXCISE

Federated Malay States.—A certificate of registration is required on all sales of rubber.

Italy.—Picric powders and other explosive products have been exempted from the manufacturing tax when destined solely for public works, or industrial and agricultural purposes.

Nigeria.—The export duties have been revised on ground nuts, oils, skins and hides.

Poland.—An increased excise duty is payable on acetic acid.

Sierra Leone.—Exports of palm oil are no longer dutiable.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains a steady tone, both home trade and export continuing to take tolerably satisfactory quantities. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal. German charcoal is again being offered.

Acetate of Lime—	
Brown	£14—£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.-1s. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Competition being met with.
Solvent	6s. per gall. 40% O.P. Fair demand.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. per lb. Weaker, with limited demand.
Crude 60's	2s. 9d.—3s. per gall. Limited business for spot delivery. No market for forward delivery.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall. A little inquiry for forward delivery.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—	
Strained	9d.—10d. per gall. Better demand. Little material available.
Unstrained	8d.—9d. per gall. Quiet.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Market very firm.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 1d.—1s. 2d. per gall. Market weak.
Solvent 90/190	1s. 1d.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 per ton.
Flaked	£19 per ton.
Pitch, medium soft	110s. per ton. Little business. Market difficult. Little inquiry forward.
Pyridine—90/140	22s.—23s. per gall. Demand good. Supplies short.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 8d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—9½d. per lb. naked at works.
Aniline Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 8d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 7d. per lb. d/d. Drums extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	12s. lb. 100% basis d/d.
R. Salt	2s. 7½d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8½d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s. per lb. d/d.
m-Toluylene Diamine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

English makers are steadily gaining ground in the manufacture of pharmaceutical chemicals with the aid of the Safeguarding of Industries Act, and whilst the present position in Germany continues supplies of chemicals manufactured abroad on a low exchange basis will gradually disappear from the market.

Acid, Acetic 80% B.P.	£48 10s. per ton.
Acid, Acetyl Salicylic	3s. 7d.—3s. 9d. per lb. Very firm. Makers fully occupied. Demand exceeds supply.
Acid, Benzoic	B.P. quality almost unobtainable. Commercial quality offered forward at 2s. 3d. per lb. for cwt. lots.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5%, for ton lots. Dearer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d.—2s. 7d. per lb. Very firm market. Expected to advance if demand continues.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5 %. Firmer.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 3s. 3d. per lb. on a short market. No supplies from Continent.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. 3d.—5s. per lb. for English make.

Ammon. Carbonate B.P.	£27 15s. per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Continental prices much higher.
Barbitone	18s. per lb. Slightly higher and in shorter supply.
Benzonaphthol	4s. 9d. per lb.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.

Bromides—	Per lb.	
Potassium	9d.—10d.	Remain very firm. Continental prices advancing.
Sodium	9½d.—10d.	
Ammonium	10d.—11d.	

Calcium Lactate	2s. 9d. per lb. for best English make. Inferior Continental supplies have almost ceased.
Chloral Hydrate	4s. 3d. per lb. Position very firm and active.
Chloroform	2s. per lb. for cwt. lots. More active.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 14s. per lb.
Hexamine	4s. 6d. per lb. for foreign makes. Manufacture in England has been discontinued since formaldehyde was removed from the dutiable list.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—Light Commercial	£36 per ton net.
Magnesium Oxide—Light Commercial	£72 10s. per ton, less 2½%. Reduced by £5 per ton.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 62s. 6d. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	2s. 11d. per lb. for carboys. Brisk market. Higher values expected.
Methyl Sulphonal	22s. per lb.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 6d.—1s. 7d. per lb. In shorter supply.
Phenacetin	7s. 6d. per lb. Steady market. English makers fully employed. Foreign supplies shorter.
Phenazone	8s. 9d. per lb. In short supply.
Phenolphthalein	8s. per lb. Very firm.
Potass. Bitartrate—99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Permanganate	9d. per lb. for B.P. crystal. Shortage of foreign supplies has enabled English makers to regain lost ground.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Salol	4s. per lb.
Silver proteinate	10s. 6d. per lb. Quiet.
Sod. Benzoate	3s. 6d. per lb. Very scarce.
Sod. Citrate, B.P.C., 1923	1s. 5d.—1s. 9d. per lb., according to quantity. Very firm, in common with other citrates.
Sod. Hyposulphite—Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 11d. per lb., and Crystal at 3s. per lb. Firm and very active.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	4s. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	10s. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s. to 13s. 6d. per lb.
Heliotropine	8s. 6d. per lb.
Iso Eugenol	15s. 9d. per lb.

Linalol ex Bois de Rose	20s. ,, ,,
Linalyl Acetate	20s. ,, ,,
Methyl Anthranilate	8s. 6d. ,, ,,
Methyl Benzoate	6s. ,, ,,
Musk Ketone	47s. 6d. ,, ,,
Musk Xylol	13s. 6d. ,, ,,
Nerolin	4s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	16s. ,, ,,

Safrol	1s. 10d. ,, ,,
Terpineol	3s. ,, ,,
Vanillin	25s. 3d.—26s. 6d. per lb. Firm with steady demand. Raw materials dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.
Anise Oil	1s. 11d. ,, ,,
Bergamot Oil	13s. 3d. ,, ,, spot.
Bourbon Geranium Oil	37s. ,, ,,
Camphor Oil	75s. per cwt.
Cananga Oil, Java	9s. 6d. per lb.
Cinnamon Oil, Leaf	5¾d. per oz.
Cassia Oil 80/85%	11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	4s. 9d. ,, ,,
Ceylon	Very little on offer.
Clove Oil	10s. 6d. per lb.
Eucalyptus Oil 70/75%	2s. 6d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil	2s. 10d. per lb. Higher prices expected.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet	11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian	34s. per oz.
Anatolian	26s. per oz.
Palma Rosa Oil	24s. 6d. per lb.
Peppermint Oil—	
English	70s. per lb. Market very unsteady.
Wayne County	15s. 6d. per lb. Market very unsteady.
Japanese	12s. 6d. per lb. Market very unsteady.
Petitgrain Oil	9s. 6d. per lb. Dearer.

TRADE NOTES

World Trade in Sulphur and Copper Sulphate

According to information in the International Year Book of Agricultural Statistics, 1922, published by the International Institute of Agriculture, Rome (price 8s.), and quoted in the *Board of Trade Journal* of November 8, Italian sulphur production in 1922 fell to 172,000 metric tons, as compared with 274,000 t. in 1921 and 385,000 t. in 1913; exports, however, increased considerably as compared with 1921, a year of intense crisis in the sulphur trade of Sicily. The United States, in 1922, maintained its sulphur out-turn (1,860,000 metric t.) at almost the highest level, which was attained in 1921, and exceeded the 1913 yield by about 1350 m.t. The exports from the United States in 1922 amounted to 496,000 m.t., a figure never previously reached.

During 1922, Germany, France, the United Kingdom, Sweden and Canada notably increased their imports of sulphur as compared with 1921 and 1913. Prices of sulphur, both in Italy and in the United States, were in 1922 fixed at a much lower level than in 1921. In the United States the monthly quotations were even below those obtaining before the war.

Production of sulphate of copper was for 1922 higher than for 1921 in France and the United Kingdom; but, whereas the French production showed a notable increase on the pre-war outturn, the yield of the United Kingdom showed a great decrease. Figures for the output in the United States in 1922 are not available, but those for 1921 indicated a great diminution in production, especially in comparison with 1913. Figures of the Italian yield in 1922 are also not available, but it may be stated that the recent growth of manufacturing plant now gives Italy the lead in capacity for producing copper sulphate.

Foreign Patents

The following table has been compiled in order to show the cost of taking out a patent in various countries:—

Country	Taxes $	Average Working Charges $	Average Total Cost $
Argentina	120	125	450
Australia	32	350	560
Austria	940	385	1,500
Belgium	480	390	950
Brazil	662	420	1,280
Canada	40	—	175
Chile	—	270	640
Cuba	—	40	180
Denmark	627	360	1,270
England	654	—	870
France	403	180	710
Germany	1,327	—	1,510
Holland	635	480	1,520
India	305	300	730
Italy	351	180	660
Japan	163	120	490
Mexico	—	—	135
New Zealand	51	300	490
Norway	337	—	510
Panama	—	45	340
Peru	—	150	410
Philippines	—	—	75
Porto Rico	—	—	75
Portugal	125	210	440
Spain	493	425	1,050
Sweden	259	—	440
Switzerland	312	385	820

These figures, it is stated, are not to be compared with the $500 estimated as the cost of a United States patent, because these figures for foreign patents pre-suppose that the application has already been taken out in the United States, which means that a large amount of hard work has been done, and the filing in a foreign country means little new thought or consideration.—(*Chem. & Met. Eng., Oct.* 15, 1923.)

Import Licences for Dyestuffs

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during November, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee :—

The total number of applications received during the month was 612, of which 485 were from merchants or importers. To these should be added 8 cases outstanding on November 1, making a total for the month of 620. These were dealt with as follows :—

Granted—433 (of which 413 were dealt with within seven days of receipt).

Referred to British makers of similar products—119 (of which 105 were dealt with within seven days of receipt).

Referred to Reparation supplies available—40 (all dealt with within two days of receipt).

Outstanding on November 30, 1923—28.

Of the total of 620 applications received, 558, or 90 per cent., were dealt with within seven days of receipt.

Foreign Company News

Switzerland.—It is reported that a company with a capital of 2 million (Swiss ?) francs has been registered under the title "Borvisk" at Zurich, for the manufacture of artificial silk by a new process due to Mr. Borzykowski.

Foreign Patent Rights in France

In 1922 the number of patents taken out in France was 18,300, of which 10,879 were due to French, and 7421 to foreign patentees. Of the foreign patentees, 1875 belonged to the United States, 1504 to England, and 1480 to Germany. Figures showing the number of chemical patents taken out in 1922 are not available, but in 1921, out of 955 chemical patents 236 or 25 per cent. were taken out by Germans, who were also the holders of 12 per cent. of all the patents of all kinds taken out in that year.—(*Chem. Ind., Dec.* 1, 1923.)

French Company News

By the end of 1924 the "Société des Produits Azotes" will possess works representing a total of 12,000—14,000 k.w., and it is hoped to produce 12,000—15,000 metric tons of calcium carbide. At present the output of calcium cyanamide lies between 40,000 to 50,000 t.

A group comprising over twenty Belgian, English and French petroleum companies has been formed in Paris, under the title of the "Comité interallié des compagnies petrolifères en Russie," to defend their rights in Russia, on the lines laid down by the assembly of the "Groupement international des Sociétés naphtifères en Russie" in September (*cf. Chem. & Ind.*, p. 1020).

Two new companies are being founded by French mining and chemical enterprises for the recovery of the by-products of coal. The first company, including the following companies :—Mines de Lens, Dourges—Nœux, Houillères de Sarre et Moselle, Cie. d'Alais et Camargue, is to utilise the Casale process to produce synthetic ammonia, a plant being erected at each battery of coke ovens belonging to the group. The second company, including most of the companies previously mentioned, is to extract and treat coal tar, in a factory to be erected at Pont à Vendin.

It is evident that there is a general tendency to similar joint action throughout the heavy chemical industry in France. Thus the amalgamation has recently been announced of the Compagnie Nationale des Matières Colorantes and the Etablissements Kuhlmann, thus leading to the formation of the sole French company with an output covering the whole realm of organic and inorganic products. The new company will be known as the Cie. Nationale de Matières Colorantes et Manufactures du Nord Réunies. Etablissements Kuhlmann. The capital of the Etablissements Kuhlmann is to be raised to 150 million fr. by the emission of 50 million shares of 10 fr. each, which will be exchanged for shares in the Cie. Nationale. In future the work will be distributed between the two companies to avoid any duplication of effort.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, DECEMBER 21, 1923 No. 51

EDITORIAL

WE have received a most interesting book on Technical Writing, by Mr. T. A. Rickard, a lecturer at the University of Harvard and some other universities. Mr. Rickard quotes a statement of Sir James Barrie that "the man of science appears to be the only man who has something to say just now—and the only man who does not know how to say it." He furnishes us with abundant instances of inaccurate, slovenly, and ungrammatical writing, of vague and high-flown phrases, and he points out to us how these can be corrected or improved. He has an excellent chapter on jargon, that prevalent infirmity which shrinks from the simple and direct, and loves the indefinite, wordy phrases, unduly crammed with meaningless prepositions. Many writers prefer the long words of Latin or Greek origin to the shorter English words; they are afraid to use the simple words and forget that the long ones are commonly so hackneyed as to be unwelcome. The style of many of the articles in our newspapers and scientific journals is deplorable, but these articles are full of stock phrases which sink into the memory and easily slip into our conversation and into any hurried writing. During our year of editorial work we regret to find we have acquired many such, and we think the surest way to spoil the lucidity of an author is to read much scientific writing. Mr. Rickard's book will not teach an author how to write well, but it will point out to him a number of common faults which can easily be avoided. Here and there are statements with which we do not agree; every now and then he quotes with dissatisfaction sentences that appear to us to be tolerable. But these are points of taste where some individuality is allowed. There is no reason why we should all adopt the same rules when we are considering minute variations of style. With nine-tenths of the examples in the book we cordially agree, and we hope that this book will be read in every university and technical college in this country.

* * *

The English language has only one reliable standard, the usage of the best writers. These do not all adopt, in trivial matters, the same practice; each author is entitled to the enjoyment of a few fads, provided that in the main he adheres to the principles accepted by the great masters of literary English. The phrases of the Authorised Version of the Bible, of Macaulay's History, of the Essays of Addison, de Quincey, Hume, Lamb and Huxley, will be a safe guide. Taste and grammar have varied a little during the last three hundred years, and some allowance should be made for these changes, but the books we have mentioned and the writings of Ruskin, De Foe, Lyell, Mark Pattison and a score of others furnish us with a good standard, adequate for our needs. Mr. Rickard has what we consider a justifiable fad in preferring, in many cases, the word "that" to "which." The rules he gives are doubtless convincing, but a rule which does not permit the phrase, "Our Father, which art in Heaven," must not be too rigidly applied. We hastily read a few pages of the Vicar of Wakefield, of Francis Bacon, Cowley, Swift, de Quincey, John Addington Symonds, Henry Mackenzie, Hazlitt, Lamb, Lyell and Giekie, and satisfied ourselves that their practice is not uniform. We confess to a few fads of our own; perhaps we are unduly annoyed by an attempt to fit together the singular and the plural; we dislike "the Company are," "the Board of Trade have," "the Chemical Society say," "the agenda provides," "optimum conditions," "those kind of things," and "none are." Among our chemists are some notable instances of writers who think clearly and write good English, but there are many who take no pride in their writing and show no signs that the perusal of transactions and abstracts has been supplemented by the reading of our standard authors. To all these Mr. Rickard's book will be amusing and valuable.

* * *

Thus with the year, seasons return; for those who have young children this is a season for school reports and school bills, for fancy dress and other parties, for cakes and ices, for late hours and indigestion. For all of us it is a time when we change our occupation, the men cut a large slice out of a working day and devote the time to hurried and concentrated shopping. We are all actors, as even more gifted authors remarked before chemistry became a science, and many of us are compelled to put aside the learned look, which is so appropriate to a lecturer or a participant in the sacred rite of titration, and to become for a brief space a Father Christmas, a Malvolio, or a Touchstone. It is refreshing to see a Fellow of the Royal Society with a false nose, or a University Professor with a burnt-cork moustache, romping with a younger generation. Those who can describe themselves as "directors of a public company" relax their eyes severe and forget their wise saws and modern instances and easily shift into the garb of a lean and slippered pantaloon. Perhaps the most agreeable change for many of us is that we shall be free for a few days from committees. Of all methods of earning an honest livelihood, talking is the most remunerative. Compare it with writing, for instance: and of the many varieties of talking, not lecturing, nor preaching, nor advocating, is so likely to lead to that combination of affluence and rheumatism which denote success, as talking at a board meeting or a committee meeting. This is a penalty of our complex civilisation; were the heroes of Homer with us now, we predict that Nestor would alone be the proprietor of a Rolls-Royce, Hector and Achilles would be glad of temporary employment in Bavaria or the Balkans, and the god-like Odysseus would find that his cunning, his fertile imagination and his disregard of the highest forms of accuracy would have involved him in monotonous and ill-paid labour on Dartmoor. But in chemical matters do we not rather overdo our committees? We probably have not too many committees in existence, but they are too large; committees which meet regularly and do useful work can act only after overcoming the inertia of the slowest members; the larger the committee, the more leisurely it operates.

MILK

By H. R. WHITEHEAD, M.Sc.

Milk is one of our most important foodstuffs, since it contains all the substances necessary for the maintenance of life: protein substances which supply tissue-building material; sugar and fat, which provide energy for both muscular work and heating; and, lastly, various enzymes, vitamins and inorganic salts, the action of which is still obscure, but which are known to be of prime importance to life. Since milk is the principal food of children and invalids, it is of the utmost importance that every care should be taken to maintain its quality and to protect it from contamination.

There are two aspects of the subject of milk production. The farmer has to look at the matter from a commercial point of view, and thus has gathered a large amount of practical knowledge concerning the breeding of cows, their feeding, and the milk production of different types. From the academic point of view, great interest attaches to the value of milk in nutrition, to its chemical constituents, and to the effect of bacterial contamination. The co-operation of both sides is necessary to solve the problem of providing the country with a supply of clean milk. In this paper, however, the matter will be considered from a theoretical standpoint, and more especially from the point of view of bacteriology.

Milk Proteins

The principal protein of milk, occurring to the extent of 3 per cent., is casein. It belongs to a class of substances of very high molecular weight, and it is moreover one of the most complex of this class. Casein is weakly acid and probably occurs in milk in pseudo-solution as the calcium salt. When diluted milk is acidified the casein is precipitated, entrapping the fat globules and leaving a clear whey. This is substantially what happens in ordinary souring. The clot of casein obtained in this manner is not the same as that formed by the action of rennet, which hydrolyses the casein into a protein, paracasein, of half the molecular weight of the original protein, and as the calcium salt of paracasein is insoluble, this separates out.

On treatment with acids, alkalis and enzymes, casein, like all proteins, is hydrolysed into simpler nitrogenous bodies and finally into amino acids. This is what happens in the body. The enzymes in the stomach and intestine, pepsin and trypsin, break down the casein molecule into soluble peptones and amino acids, which can pass into the blood stream, there to be rebuilt, so to speak, into the proteins of animal tissue.

These hydrolytic reactions are also made use of in bacteriology for the preparation of culture media, since micro-organisms require amino acids or similar bodies for their nutrition.

For example, when trypsin, the enzyme of the pancreas, is allowed to act upon casein at 37° C. for ten days, a clear brown fluid results which forms an excellent medium for the growth of many bacteria.

Milk also contains about 0·4 per cent. of other proteins which differ from casein in that they are coagulated by heating to about 70° C. These proteins are known as lactalbumin and lactoglobulin, and, together with a certain amount of fat, constitute the skin which forms on the surface of boiled milk.

MILK SUGAR

The sugar, which constitutes 3·74 per cent. of cow's milk, is lactose, a disaccharide like cane sugar, but less soluble and much less sweet to the taste. On hydrolysis it breaks down into galactose and glucose, sugars which can be assimilated by the animal body. Many micro-organisms can ferment lactose, forming lactic acid as a main end-product. When this happens in milk we get the familiar souring with precipitation of casein.

MILK FAT

Milk fat consists of a mixture of the glycerides of at least nine fatty acids, and is found in the shape of small globules, varying in size from 0·01 mm. to 0·0016 mm. Owing to their high refractivity the globules can readily be seen under the microscope, the smaller drops showing Brownian movement. On standing, the droplets slowly coalesce and rise to the surface of the milk as cream. The determination of the fat content is one of the necessary tests of milk under Government regulations, 3 per cent. being the lower limit allowed.

OTHER CONSTITUENTS OF MILK

Besides the proteins, fat and sugar, milk contains about 0·75 per cent. of mineral salts (mainly chlorides and phosphates), traces of urea, hypoxanthine and other nitrogenous bases and colouring substances. Several enzymes and some vitamins give evidence of their presence, but their chemical nature is so far entirely unknown.

The Government regulations require that the percentage of total solids not fat in milk shall not fall below 8·5 per cent., so that in addition to the fat, the total milk solids must be estimated by evaporating a definite quantity of milk to constant weight on a water bath. The object of this test is to detect any adulteration. It might be thought that a determination of the specific gravity would suffice, but as the removal of fat would raise the density, and since adding water would lower it, a skimmed milk adulterated with water might well have the same density as a genuine milk.

PRESERVATION OF MILK

The problem of keeping milk at a fairly constant chemical composition is comparatively simple when compared with that of preventing changes taking place during distribution. Milk is an ideal medium for bacterial growth, and its temperature at the time of milking is especially favourable for the growth of micro-organisms. Thus it is practically impossible to keep the milk in the sterile condition in which it leaves a healthy cow's udder, much less so when the conditions of milking and distribution are not of the cleanest. Bacteria from the coat of the cow, from the air of the byre, from the person of the milker, and from the vessels used, all gain access to the milk. Many of these organisms are harmless, both as regards their effect on human beings and their power of producing changes in the milk, but the total number of organisms present in any sample affords a good indication of the degree of contamination. The only method of ensuring that disease-producing organisms shall not be present, is to prevent the introduction of any organism whatever, *i.e.*, the milk must be kept sterile.

It is important to point out the fallacy that exists in the "dirt test" sometimes applied to milk as a criterion of cleanliness. Many bacteria gain access to the milk in company with particulate matter, such as hay, straw and manure, but since filtration through muslin or cloth will remove much of the dirt without affecting the bacterial content in the slightest, it will be clear that the sediment test determines the efficiency of the straining rather than the bacterial contamination, which is much the more important point. In other words, a well strained but contaminated milk may appear much cleaner by the sediment test than one produced with more care but less efficiently strained. As Savage says, "Take care of the bacteria and the sediment can take care of itself."

BACTERIA IN MILK

The bacteria found in milk may be classified as :—

(A) Non-pathogenic organisms
(B) Pathogenic organisms

The most important of the first class of organisms from the dairyman's point of view are the lactic acid bacilli. These are rod-shaped organisms which ferment lactose, lactic acid being the main, but not the only, substance formed. Traces of the following substances have been detected in sour milk: acetic, butyric and succinic acids, carbon dioxide, hydrogen and alcohol. This group of bacilli may be subdivided into :—

(i) Bacilli which form acid and gas.
(ii) Bacilli which form acid alone.

The main organisms comprising the first subdivision are *B. coli* and *B. lactis aerogenes.*

These are particularly important from the point of view of public health, as they are almost invariably derived from the excreta of the cow, and their presence in milk indicates the degree of pollution. The test for the presence of these organisms is part of the routine of bacteriological examination of milk.

The other bacilli in the second subdivision, such as *B. acidi lactici* and *B. bulgaricus,* are useful rather than harmful, because the reactions they bring about tend to inhibit the growth of pathogenic organisms, and further, by producing changes in the milk (souring and clotting) they prevent the sale of stale milk laden with other possibly harmful bacteria, which give no such indication of their presence.

Next in importance among the non-pathogenic bacteria found in milk are the streptococci, round organisms which grow in chains, varying in length according to the type of organism and the conditions of growth. They are sometimes derived from the cow's udder if this is affected with inflammation, or mastitis, and as cow dung contains on the average 10–100 million streptococci per g. they may gain access to the milk in the same way as *B. coli*, through faulty milking. Many streptococci ferment lactose, producing acid, and some observers have isolated a lactic acid streptococcus, bringing about the same changes as *B. acidi lactici.* Although the streptococci are included among the non-pathogenic organisms, their presence in milk is regarded with suspicion, some observers claiming that they are the cause of gastro-intestinal catarrh, infantile diarrhœa, and sore throat in human beings. But the identification of streptococci is still not satisfactorily worked out, so that the issue is obscure.

Another coccus present almost invariably in milk is *Staphylococcus,* an organism similar in shape to *Streptococcus,* but growing in clusters instead of chains. There are many varieties of the organism, but as their effect on milk is not to be compared with that of the lactic acid organisms, and as they have no harmful effect on human beings in the general way, no great interest attaches to their presence.

The next group of organisms is that of the spore bearers, of which there are both aerobic and anaerobic varieties. These are rod-shaped organisms which have the power, when in surroundings uncongenial to their growth, of changing into a round or oval form very resistant to destruction by drying, heat or antiseptics, and remaining in a quiescent condition until they find themselves once more in a suitable medium, when they resume their vegetative form and reproduce in the usual way. These organisms became prominent during the war as being the invading agent in cases of gas gangrene. Some of the spore-bearing bacilli will grow only in the absence of oxygen, and of these *B. Welchii,* derived from cow dung, is sometimes present in milk. It does not grow in the milk, being an anaerobe, and is non-pathogenic to man, except in special conditions, such as lacerated wounds, but its presence affords evidence of manurial contamination. Milk containing the spores of the organism and incubated (after being heated to 80° C. for 30 mins. to destroy other organisms) under anaerobic conditions, soon exhibits well-marked changes : the casein separates as a clot, and there is abundant gas formation.

The aerobic spore-bearing bacilli found in milk are derived mainly from hay and straw, and are non-pathogenic, but decompose the milk proteins. Since all the sporing organisms are very resistant to heat, they constitute one of the greatest difficulties to be overcome in the sterilisation of milk.

The organisms enumerated constitute the majority of those found in milk, but since milk is such an excellent medium for bacterial growth and is exposed in so many ways to infection, there is really no end to the varieties of organisms which may be found. There are organisms which cause various colour changes, blue, red and yellow, and almost invariably yeasts and moulds are present. The only other organisms which require mention are those pathogenic to man.

PATHOGENIC ORGANISMS

Milk has been shown to be the carrier of the infecting agent in epidemics of cholera, typhoid fever, scarlet fever, diphtheria, malta fever and sore throat. The infection of the milk by the specific organism of a disease is generally brought about by some person who is suffering or recovering from the disease, or who is a "carrier" of that particular organism, *i.e.,* he exhibits no symptoms of the disease although he harbours the organism and spreads infection. Typhoid fever may also gain access to milk through polluted water used to wash out the milk vessels. Most of the pathogenic organisms occuring in milk cause no obvious changes such as souring and clotting, and their presence is generally only discovered after they have caused illness in human beings.

TUBERCULOSIS

By far the most common pathogenic organism found in milk is *B. tuberculosis,* which occurs in the milk of cows suffering from the disease not only when localised in the udder but in any part of the body. For many years there was doubt whether tubercle bacilli of bovine origin could cause tuberculosis in human beings, but it is now established that many cases of tuberculosis are caused by infection from tuberculous milk. It has been found that 86·6% of the infections of children up to 5 years old suffering from tuberculosis of the cervical glands are bovine in origin. In 1068 cases of various tubercular lesions the following percentages proved to be of bovine type.

Age	Per cent
0—5	37·5
5—10	29·45
10—16	14·66
Over 16	6·25

B. tuberculosis does not multiply to any extent in milk, and the surest method of detecting its presence is to inject the milk into the peritoneum of a guinea pig. If tubercle bacilli are present, the animal develops the disease, and at the end of about six weeks a post-mortem examination will reveal specific lesions. This examination is continually being carried out with samples of milk offered for sale, and where milk is found to be tuberculous the infected animal is traced, if possible, and removed from the herd.

Another method of detecting tuberculosis in cows is by applying the tuberculin test. Tuberculin is a fluid prepared by growing tubercle bacilli in glycerin veal broth, sterilising in an autoclave, concentrating *in vacuo* and filtering. If an appropriate dose be injected into an animal suffering from the disease, a well marked reaction indicated by a rise in temperature takes place, whereas in most healthy animals no reaction occurs; 0·4% of normal bovine animals do, however, give a reaction. In this way tuberculous animals can be eliminated with a fair degree of certainty from any herd.

STANDARD MILK

Milk is usually sold without any restriction as to its bacterial content; it merely has to satisfy the chemical standards. The Government is, however, proceeding along the right lines in introducing standards to which milk dealers can voluntarily conform. Ultimately it is to be hoped that all milk sold will satisfy these standards. There are, under the recently introduced regulations, three grades of milk apart from ordinary ungraded milk :—

I. Grade A certified milk.

II. Grade A milk (which may also be tuberculin tested).

III. Pasteurised milk.

This grading deals purely with the bacterial content, since all milk must perforce conform with the chemical standards. The significance of the grades is as follows :—

Grade A certified milk must be produced from tuberculin-tested cows and must not contain more than 30,000 organisms per c.c. as delivered to the consumer. The test for *B. coli* must be negative in 3 tests of 0·1 c.c.

Grade A milk must contain less than 200,000 organisms per c.c. as delivered, and the *B. coli* test must be negative in 3 tests of 0·01 c.c. There is no absolute guarantee that the milk is not tuberculous, unless it is specifically stated to be from tuberculin-tested animals.

Pasteurised milk must have undergone an approved method of heat treatment, and must not contain more than 50,000 organisms per c.c.

When milk is sold under any of these three labels it is tested periodically in the bacteriological laboratory. An inspector collects a bottle of the milk during delivery, puts it into a special ice box and delivers it at the laboratory. The testing of the milk is then carried out as follows. The bacteriologist has before him three bottles each containing 90 c.c. of water, plugged with cotton wool and sterilised. With a sterile 10 c.c. pipette he measures 10 c.c. of milk into the first bottle, inserts a sterile rubber stopper and shakes the bottle thoroughly. With a second sterile pipette he measures 10 c.c. from the first bottle into the second, inserts a stopper and shakes. Similarly 10 c.c. are transferred from the second to the third bottle. Thus three dilutions, $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, of the milk are obtained. Next 1 c.c. of each dilution is pipetted off with a sterile pipette, mixed with 15 c.c. of melted medium in a tube and the tubes poured into sterile glass Petri dishes. The medium is made from commercial peptone, Lemco meat extract, and agar, a solidifying agent. It is prepared according to standards laid down by the Ministry of Health so that constant results are obtained throughout the country. The plates of medium are then allowed to set.

The *B. coli* test is carried out by pipetting 1 c.c. from the appropriate dilution bottle into a tube containing McConkey's broth. This broth contains peptone, lactose, litmus as an indicator and bile salt or sodium taurocholate which favours the growth of *B. coli* and tends to inhibit other organisms. In the tube, a smaller test tube is inverted in the broth. If *B. coli* is present in the milk it forms acid and gas from the lactose; the acid is indicated by the reddening of the litmus and some of the gas is trapped in the small tube. The presence of *B. coli* is only taken as proven when both acid and gas are producedi because other organisms such as the streptococc, produce acid only from lactose.

When the agar has set, the plates are incubated, together with the McConkey tubes, in an incubator at 37° C. The first reading of results is made after 48 hours, when the McConkey tubes are examined and the colonies on the three plates counted. The plate prepared from the 1 in 10 dilution contains the organisms from 0·1 c.c. of the original milk and the other two contain those from 0·01 and 0·001 c.c. respectively. Each colony is assumed to have originated from one organism in the milk. From the counts of the three plates the number of bacteria in 1 c.c. of the original milk is calculated by averaging. The McConkey tubes after having been read are incubated for a further 24 hours before the final reading is made, when they are marked as positive or negative.

It is of little use to introduce bacteriological standards unless all those who have to deal with milk learn how to avoid bacterial contamination. In milking, all that is required is extreme cleanliness; the cow's udder and flanks should be washed; the byre should be kept clean and as free as possible from dust; the milker should wash his hands immediately before milking and should wear a clean overall; the milk vessels should be sterilised by scalding before use and they should be kept covered when containing milk.

Most of the organisms found in milk grow best at the temperature of the human body, 37° C. As the milk leaves the cow it is roughly at this temperature and the organisms which do gain access to it, however great the care of the milker, begin to multiply rapidly unless checked. The further the milk has to travel the greater the bacterial content when it reaches the consumer.

There are three main ways of keeping down the number of bacteria, viz., by (1) efficient cooling, (2) pasteurisation or sterilisation, and (3) the addition of antiseptics.

The first method is the only really satisfactory one at the present time. In milk kept at freezing point the bacteria will not multiply to any extent for several days, whereas there may be a 14-fold increase in 24 hours in milk kept at 15° C. Of course the cooling will not eliminate disease germs if these have entered the milk already. It should be emphasised that cooling to temperatures far below 0° C. does not kill bacteria.

The second method consists in heating the milk above the thermal death point of the organisms present and thus rendering it sterile. The disadvantage of the method lies in the fact that a temperature sufficient to destroy with certainty all the organisms including spores will bring about chemical changes in the milk, altering its taste, and perhaps destroying vitamines and enzymes valuable in nutrition. Any temperature above 60° C. will almost certainly bring about chemical changes and since spores can only be destroyed at temperatures over 100° C. or by heating to boiling point several times in succession it will be seen that it is almost impossible to obtain unaltered sterile milk by any method of heat treatment. According to the latest results *B. tuberculosis*, the most resistant of the vegetative bacteria, is killed in milk by heating to 60° C. for 20 minutes.

The third method is bad since a substance capable of destroying bacteria in milk, generally has a harmful effect on human beings and especially on children. Substances commonly added to milk are boric acid, formaldehyde, sodium carbonate, and salicylic acid. Their use merely stifles the bacteria, disguises the true condition of a contaminated milk and puts a premium on uncleanly dairying. Consequently the use of antiseptics and preservatives is prohibited by law.

The soundest method therefore of keeping down the bacterial content of milk is by clean milking and by maintaining the milk at a low temperature during delivery. The practice of delivering milk in sealed bottles is infinitely preferable to delivery in bulk and the subsequent measuring out of smaller quantities in a dusty street. Finally the milk must be produced from healthy cows and no one concerned in its production or distribution must be a disease carrier.

In conclusion I would quote a rather humorous paragraph from Savage's *Milk and Public Health*, referring to the present methods of delivering milk.

"The dairy shops scattered about the towns are usually scrupulously clean, the milk vessels are equally clean and the attendant neat and tidy. Indeed for those who know the average conditions under which milk is produced and the gross contamination to which the milk sold in such dairies has probably been subjected, there is keen irony in the beautiful surroundings which envisage the milk as soon as it comes within the purview of the consumer and a whited sepulchre comparison is felt to be not unwarranted."

RESINS IN THE FAR EAST

Copal, dragon's blood, gamboge, gurjunbalsam, elemi and rosin are the principal resins produced in Eastern Asia. In 1920, 1,019,834 kg. of copal was exported to India, Great Britain, United States, Belgium, France, Spain, Japan, China and Australia, and in 1921 the total shipments were 542,700 kg. Large quantities of dragon's blood (obtained from *Calamus draco*, which grows in the Dutch East Indies, Straits Settlements and the Federated Malay States) is shipped to India, China and Europe from Singapore and Batavia, the two chief export centres. Several trees produce gamboge, the chief variety coming from *Garcinia morella*, which flourishes in Siam, the islands on the east coast of the Gulf of Siam, various parts of India and the southern areas of Cochin China. The chief export centres are Bangkok, Saigon and Singapore. Gurjunbalsam, which is exported chiefly from Singapore, is an oleo-resin obtained from several species of *Dipterocarpus*, of which *D. turbinatus* is found in the Straits Settlements and French Indo-China and *D. trinervis* in Java and the Philippines. The trade in gurjun is mostly carried on between various Eastern countries, and some is also shipped to America and Europe. Kwangtung and Kwangsi, provinces of China, are the chief sources of supply of rosin in Eastern Asia, shipments being exported from Kowloon, Canton, Swatow and Wuchow. Hongkong imports practically all the Chinese output of rosin, Japan being the next largest purchaser. Elemi is produced in the Philippines, Great Britain and the United States being the largest importers.—(*Ch. Comm. J., Oct.* 5, 1923.)

FORTHCOMING EVENTS

Dec. 29 to Jan. 9. Scientific Novelties Exhibition, King's College, Strand, W.C. 2. Demonstrations and Experiments, 2—5 p.m., and 6—9 p.m.

Jan. 2. Institution of Electrical Engineers, *Wireless Section*, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "Some Experiments on the Screening of Radio Receiving Apparatus," by R. H. Barfield, M.Sc.

Jan. 3. Society of Chemical Industry, *Bristol Section*, Chemical Department, The University, Bristol, at 7.30 p.m. "The Chemical Technology of Canned Foods," by O. Jones.

Jan. 7. Institution of Electrical Engineers, Savoy Street, Victoria Embankment, W.C. 2, at 6 p.m. "Troubles with Domestic Electrical Appliances." Discussion opened by J. W. Beauchamp.

Jan. 7. Society of Chemical Industry, *London Section*, in the Rooms of the Chemical Society, Burlington House, W. 1, at 8 p.m. "The Estimation of Butyric Acid in Presence of Acetic Acid," by Dr. E. Fyleman; "The Estimation of Cadmium in Spelter and Zinc Ores," by C. E. Barrs.

Jan. 7. Institution of Rubber Industry, *London Section*, The Engineers' Club, Coventry Street, W. 1, at 8 p.m. "Consistency of Rubber and Rubber Compounds," by Dr. S. S. Pickles.

Jan. 8. Institution of Mechanical Engineers, *Swansea Section*, at Chamber of Commerce, Swansea, at 6 p.m. "Modern Developments in Steam Raising," by Sir J. H. R. Kemnal, F.R.S.

Jan. 8. Institute of Metals, *Birmingham Section*, Chamber of Commerce, New Street, Birmingham, at 7 p.m. "Nickel Brasses," by O. Smalley.

Jan. 8. Institute of Metals, *North-East Coast Section*, Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "The Action of Molten Brass on Nickel-Steel," by H. M. Duncan, B.Sc.

Jan. 10. Institute of Metals, *London Section*, Institute of Marine Engineers, 85—88, The Minories, Tower Hill, E. 1, at 8 p.m. "X-Rays and Metallurgy," by W. T. Griffiths, M.Sc.

Jan. 10. Institution of Mechanical Engineers, *Glasgow Section*, Royal Technical College, Glasgow, at 7.30 p.m. "Radiation and Atomic Structure," by Prof. J. Muir, D.Sc.

Jan. 11. Institute of Metals, *Sheffield Section*, The University, St. George's Square, Sheffield, at 7.30 p.m. "Influence of Casting Temperature on the Physical Properties of Metals," by F. H. Hurren. (Conjoint Meeting with the Institute of British Foundrymen).

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

EDITORIAL NOTICES

The Society as a body is not responsible for statements and opinions appearing in the Journal.

Members of the Society, and others, are invited to submit original articles, news, notes and other relevant information to the Editor of *Chemistry & Industry*. Such contributions should be clearly written (preferably typewritten with double spacing), and be accompanied by a stamped and addressed envelope. They will be paid for if inserted. Sources of information should always be given, not necessarily for publication.

Hon. Secretaries of Local Sections and of other Societies are asked to forward notices and reports of meetings as early as possible, and publishers to send books for review, direct to :—The Editor, *Chemistry & Industry*, Society of Chemical Industry, Central House, Finsbury Square, E.C. 2. [Telephone: Clerkenwell No. 2429.]

Hon. Secretaries of Local Sections and of other Societies are asked to note that announcements of forthcoming events cannot be inserted in the next issue of the Journal *unless they are received not later than Tuesday in any week.*

Matters relating to the Transactions and Abstracts, including Papers intended for insertion as Communications, should be addressed to The Editor of Transactions, at the same address.

CHEMICAL SOCIETY'S LIBRARY

The Library of the Chemical Society will be closed for the Christmas Holidays from Monday, December 24, to Thursday, December 27, inclusive.

LIST OF MEMBERS ELECTED

December 14, 1923

Bishop, Wilfrid B. S., Department of Chemistry, The University, Sydney, N.S.W., Australia. Demonstrator.

Boan, R. Farquharson, Borthwicks Pty., Ltd., Elizabeth Street, Waterloo, N.S.W., Australia, Chief Chemist.

Briggs, Chas. V., 126, Glenville Avenue, Allston 34, Boston, Mass., U.S.A. Chemist.

Campbell, George I., 63, Palace Road, Tulse Hill Park, London, S.W. 2. Wax and Oil Merchant.

Cocks, Leslie V., 38, Egerton Park, Rock Ferry, Cheshire. Research Chemist.

Coutinho, Dr. Constancio, Municipal Offices, Victoria Terminus, Bombay. Municipal Analyst.

Eadie, Robt. G. W., 22, Whitevale Street, Dennistoun, Glasgow. Chemist.

List of Members Elected (*cont.*).

Garrod-Thomas, R. Noel, 166, Piccadilly, London, W. 1. Barrister-at-Law.

Heaton, John S., C.P.A. Central Laboratory, Rhodes, near Manchester. Research Chemist.

Hetherington, Arthur C., St. Kitts, Slateford, Midlothian. Research Student.

Hill, J. Bennett, The Barrett Co., Frankford, Philadelphia, Pa., U.S.A. Chemist.

Hirst, Joseph F., 3, Wolseley Gardens, Gunnersbury, London, W. 4. Chemist.

Hoffert, Wilfred H., Dept. of Coal Gas and Fuel Industries, The University, Leeds. Research Chemist.

Holmyard, Eric J., The Brow, Clevedon, Somerset. Schoolmaster.

Honey, Harry E. E., Incorporated Oil Seed Association, Exchange Chambers, 24, St. Mary Axe, London, E.C. 3. Analytical Chemist.

Hopkins, David G., Physical Chemistry Dept., The University, Bristol. Research Chemist.

Hotton, Donovan H., c/o Messrs. Bristowes Tarvia, Ltd., St. Stephen's House, Victoria Embankment, London, S.W. 1. Technical Chemist.

Louden, Chas. R., 4, South View, Dalmuir, Dumbartonshire. Chemist.

McLeod, William G., The Harris Abattoir Co., Ltd., Toronto, Ont., Canada. Chemist.

Malcolm, George, 12, Miller Street, Shawlands, Glasgow. Chemist.

Mann, William, 2, Albin Street, Morley, near Leeds. Textile Chemist.

Mieras, Adrian P., Keith Lodge, Beaverhall Road, Edinburgh. Analytical Chemist.

Miller, Stuart P., The Barrett Co., Margaret and Bermuda Streets, Frankford, Philadelphia, Pa., U.S.A. Chemist-Superintendent.

Morrison, Robert E., c/o Blanchard, 9, Antigua Street, Edinburgh. Chemist.

Munro, Reginald J., "Dunmore," Eccles Road, Hunters Quay, N.B. Chemist.

Read, Harold R., 62, Dale Street, Liverpool. Analyst.

Reid, John H., Westgarth, Formby, Lancs. Chemist and Manager.

Scholes, George R., Oxo Factory, Southwark Bridge, London, S.E. 1. Technical Chemist.

Schorman, William A. P., 51, Douglas Drive, Toronto, Ont., Canada. Consulting Engineer.

Slater, Albert V., 20, Clifford Street, Hornsea, E. Yorks. Chemist.

Tait, John B., 32, Ryehill Terrace, Leith. Works Chemist.

Walker, George, "Aldersyde," North Street, Stanmore, Sydney, N.S.W., Australia. Demonstrator in Chemistry.

Whytlaw-Gray, Robert W., The Chemistry Dept., The University, Leeds. Professor of Chemistry.

Williams, Edward T., 49, Grasville Road, Higher Tranmere, Birkenhead, Cheshire. Research Chemist.

Wood, Benjamin, 10, Mansard Close, Jeffcock Road, Wolverhampton. Analyst.

Wright, Ethel C., c/o Leach Neal and Co., Ltd., Spondon, near Derby. Industrial Chemist.

LIVERPOOL SECTION

A meeting was held in the Rooms of the Over-Seas League, on November 30, Mr. Edwin Thompson, the Chairman of the Section, presiding. The principal business of the meeting was a discussion on "The Society of Chemical Industry and what it stands for," which was opened by the President, Dr. E. F. Armstrong, F.R.S.

The Chairman, before calling upon Dr. Armstrong, said that it was hoped to make the Section as useful to everyone as possible and to induce members to attend the meetings because they found them interesting, and not merely as a matter of duty. The Sections should be a real help to the Society, and he hoped that the President would go back convinced that the Liverpool Section was doing its share.

The President said that a Society such as the Society of Chemical Industry had two main purposes. The one was to be of assistance to the academic chemist; the other to represent those engaged in industrial chemistry. The Society was really complementary to the Chemical Society, because papers were read before its Sections dealing with the industrial side of the science. Their past records contained many very important papers, and their abstracts had been an achievement of which they were justly proud. The Institute of Chemistry represented, in the main, professional chemists, and could not cater altogether for that large class which was engaged in chemical industry. Our Universities were turning out hundreds of highly trained men, and they were naturally asking if the Society could not do something for them. He (the President) thought that there was great scope for assisting these chemists, and nothing fitted a man better for his career than a scientific training, although he need not necessarily become a chemist. In after life, though he might go in for finance, commerce or some other branch of business, he would be none the worse for a preliminary training in science. Every year the world was becoming more scientific; educated men were expected to understand technical matters of which their fathers knew nothing, and they found this scientific knowledge of use to them. What they required was some chemical body to keep these men in touch with science, and he would like to see such persons members of our Society, attracted to it by its activities, by its Journal and by its club life. He had felt a certain sense of shame that a body of the importance of the Society of Chemical Industry had no meeting place of its own, and this aim might be realised if all these people on the fringe of the profession, but who were not actually chemists, would join with them. He did not know what could be done to make the meetings more attractive, but he felt that they must endeavour to interest people outside the profession, and by so doing they would provide better opportunities for chemists.

Prof. I. M. Heilbron agreed that it was necessary to obtain the active support of some of those on the border line of chemistry, and get them to attach themselves to the Society. He asked if it would not be possible to associate with other bodies in Liverpool, so that the aims and objects of the Society should be more widely known, and thus the position of chemistry strengthened. He foresaw the difficulty as the years went on of maintaining sectional meetings, owing to lack of appropriate material for papers. He suggested that the experiment might be tried of inviting members of the Institute of Chemistry to attend the meetings and thus ensure closer co-operation. Similarly, meetings with other local societies might be arranged. The Chairman mentioned that it was proposed to hold a joint meeting with the Liverpool and North-Western Section of the Institute of Chemistry on January 18. Mr. W. Mansbridge pointed out that there was co-operation between the learned societies of the district; last year a delightful soirée was held in the Liverpool Museums, and among other activities of the Committee of Learned Societies, the proposal to obtain a common meeting place was under consideration.

Mr. A. A. Robertson observed he was glad that there was a desire to instil life into the Section. He thought that a closer connexion between the University and industry in Liverpool would be a great advantage, and that the Section could provide a suitable meeting-ground. Students of chemistry should be invited to attend. Dr. C. H. Clarke said that by working together and getting the support of the heads of the profession they would be able to interest others in influential quarters. People looked to the Society to keep chemists together, and he thought that they would get larger attendances if popular subjects were chosen rather than technical ones. Mr. A. T. Smith strongly endorsed the President's suggestion that a training in chemistry would serve a man well in after life. It would be useful in giving him an appreciation of the value of exactitude. Their Society was one which diffused knowledge of chemistry, and he thought it would do a great deal of good if they could get some of the older members to come among them and talk things over. If they could infuse more life into the Society it would be a very good thing.

Mr. E. H. Shepherd pointed out that the Society was working on much the same lines as the Institute of Chemistry, and that what was required was to co-ordinate the work of the two. What was needed was the right "emulsifying agent." Mr. J. C. Cunningham pleaded for the junior members, and suggested that they might be specially invited to speak at the meetings. Mr. T. W. Stuart, speaking as a member of the Society since the commencement, thought that they had not much to complain of. They had papers of general interest, and he had found that the meetings enabled them to get to know one another and to revive old friendships. He regarded the social side as of importance, and he thought they should try to induce the seniors to attend more frequently; it would be to the benefit of the younger members. Prof. W. H. Roberts agreed with Mr. Stuart that the older members should attend the meetings as much as possible, as the younger men did not get much opportunity of meeting them. If they intermingled more it would be better for both.

Prof. Baly fully concurred in the view expressed by the president that an education in chemistry was an admirable one. The value of this education lay in the fact that students, after graduation, gained great advantage by undertaking research work, during which they learned to think for themselves and to apply the knowledge they had obtained as undergraduates since they were breaking new ground. He felt that a University education in chemistry, including agricultural chemistry, would be an excellent one for all owners of land. It might be thought worth while to discuss the proposal with the Council of the University. As regards the suggestions made for the sectional meetings, he rather deprecated the advertisement of the work done by chemists. The proposal to approach the citizens of Liverpool, possibly through the Rotary Club, with the view of interesting them in the many activities of chemists appealed to him. Too many papers on pure and applied chemistry of the ordinary type should not be read, as in his opinion members felt more interest in matters outside their ordinary day's work. He appealed for more papers of the type of the chairman's address and as an instance suggested a paper and discussion on the chemistry of photography.

On December 12 a Joint Meeting with the Chemical Engineering Group was held at the Over-Seas Club, Mr. Edwin Thompson in the chair.

A paper was read by Mr. J. T. Brewis on "The Extraction of Oil from Seeds, Nuts and Kernels." The author dealt firstly with the variable nature of the raw materials handled and with the methods adopted for cleaning, and described separators, seed and lint cleaners, and the arrangement of plant for cleaning seed and lint. The linting and defibrating process was discussed and illustrated, and a comparison drawn between the English method of pressing cottonseed and the American process, which involves previous decortication. Decorticating plant was described and also types of magnetic separators through which all seeds should pass before milling. The subsequent operations of reducing, milling, cooking and pressing were described in detail and types of open and closed presses shown. The author then proceeded to describe the extraction of oil by means of solvents, the relative merits of various solvents being discussed. Illustrations were given of plant for washing and for the separation of oil and solvents.

A discussion followed in which Mr. Reavell, chairman of the Chemical Engineering Group, Prof. J. W. Hinchley, and Messrs. Austin, Briggs, Savage and Sibbald took part.

Previous to the meeting a party was conducted through the African Oil Mills (Co-operative Wholesale Society, Ltd.), by the courtesy of the Directors, and at the close of the proceedings the officers and committee of the Chemical Engineering Group and the Lecturer were entertained to dinner at the University Club.

NOTTINGHAM SECTION

At the meeting, held on December 12, Prof. A. R. Ling gave a lecture entitled "Some Points in the History of Fermentation, particularly as Applied to the Brewing Industry."

Prof. Ling introduced his subject by defining fermentation as a phenomenon, directly or indirectly connected with life, producing a simplification of chemical substances (catabolic changes), accompanied by evolution of heat. The reactions attending the processes of respiration, digestion, assimilation, excretion and putrefaction all came under the heading of fermentation.

The lecturer then outlined the historical development of fermentation processes, the first recorded being the making of wine from rice and bread from wheat in 1998 B.C. by Ching-Nouang in China. The Egyptians made beer from barley as early as the Fourth Dynasty.

During the period of alchemy (350-1525 A.D.) many theories to explain fermentation were put forward, but it was not until 1648 that Van Helmont came near to the discovery of the living nature of yeast by observing that during fermentation something passes from the ferment into the fermenting liquid, and it is the growth of this something which actually causes the fermentation. In modern times the theory of alcoholic fermentation could be traced through three distinct epochs—chemical, biological and biochemical. Stahl considered that a ferment was a body in a state of active motion which it could communicate to another body, and later Lavoisier showed that when sugar was fermented the weights of alcohol and carbon dioxide produced were together equal to the weight of sugar. Latour and Schwann independently and almost simultaneously asserted that yeast was a living organism—a theory ridiculed by Wöhler and Liebig.

The second epoch (biological) opened with the work of Pasteur, who stated that "alcoholic fermentation is a phenomenon correlated with the life, and not with the death of yeast." The researches of Pasteur forced Liebig to admit the living nature of yeast, although he still maintained that the life of yeast was a thing apart from fermentation.

In the third epoch (biochemical) the views of Pasteur and Liebig were linked up in 1897 by Buchner, who discovered that the yeast cell contained an enzyme (zymase) which could convert sugar into alcohol.

Prof. Ling then described the processes of malting and brewing, mentioning the pioneer work of H. T. Brown and O'Sullivan, and the value of the chemical training which had enabled them to improve the industry so successfully. Finished malt contained very little maltose, but chiefly starch with a little saccharose. After discussing the fermentation of wort, the different races of yeast were described and the curious intraconvertibility of different yeasts, such as top and bottom yeasts, pointed out.

Prof. Kipping asked what was the explanation of the formation of saccharose during germination, and why one yeast could take on other functions (after a time). Mr. Pentecost referred to the use of thin starch in stiffening textiles and asked if it could be determined when the thinning (say with diastase) had gone far enough; also if boiling the starch solutions would completely destroy all enzymes.

Prof. Ling, in reply, said that the production of saccharose during fermentation had yet to receive a proper explanation; it was similar to the conversion of the starch of green apples into varying amounts of invert sugar and saccharose during ripening. With regard to the intraconvertibility of yeasts any yeast was a product of its environment. Thus in the four systems of wort fermentation, each system had its own yeast, and at first a different yeast will spoil the brew. After a time, however, such a yeast will change its characteristics and be capable of performing different functions—gradually becoming accustomed to the altered conditions. It should not be difficult to regulate the action of diatase on starch, and the polarimeter, and Fehling's and the iodine reactions could be used to follow the change. All enzymes in the starch solution would be destroyed by boiling, but this should be done rapidly; alkali (10 per cent.) would also destroy enzymes in starch solution.

NEWCASTLE SECTION

At the meeting held on November 28, Mr. Arthur Trobridge in the chair, a vote of sympathy was extended to the relatives of the late Dr. J. E. Stead. Subject to the approval of the Council, it was decided to admit Associate Members. It was announced that the Saville Shaw Memorial Medal had been awarded to Mr. Stanley Peat for his special work on the analysis of the old Chinese alloy, "Tutaneg."

A paper was read by Mr. W. S. Coates on the "Utilisation of Low Grade and Waste Fuels in Power Production." The paper dealt with the methods adopted by The Newcastle-on-Tyne Electric Supply Co., Ltd., to produce electrical energy at a very low cost. The company produces the highest amount of power per pound of coal burnt, the fuel used being largely low-grade coal containing a high ash content (up to 30 per cent.) and of relatively low calorific power. This fuel is, as a rule, of very small size, about 40 to 50 per cent. passing through ¼-in. mesh sieve. The paper was illustrated by slides, which depicted the various boilers, grates and automatic pulverisers utilised.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

On November 30, the Economic Group met, under the presidency of M. Duchemin to hear an address by Prof. H. Hauser, on "American Industry."

Prof. Hauser, who has recently been "exchange professor" at Harvard University, said that the dominant character of American production is the attempt to obtain the maximum yield with the minimum of effort. The rhythm of industrial life in America is accelerated, and everything is organised to maintain that acceleration by speeding up methods of working. After describing means of transport, Prof. Hauser indicated the importance given to technical education in the universities, to which are attached veritable works with admirable equipment. Another impression remaining from a stay in the United States was the immensity of that country's resources, whether in minerals or crops. The use of electricity was a common feature of daily life, and this favoured the installation of enormous electric generating stations, some of which even now were not charging prices more than those of 1913. However, as everything is directed towards maximum output without care of rational utilisation, there is an immense wastage of raw materials. Coal is extracted by defective processes, the intensive manufacture of wood pulp is carried out without care to conserve the forests, and the production of petrol is insufficient in comparison with the development of the engineering and motor car trades. In contrast to the wastage of raw materials the greatest care was taken to economise labour, to maintain the productive capacity of each workman at its best and to close the country to immigrants unsuited to industrial life. A consequence of this economy of labour is the extraordinary development of machinery to reduce the human factor as far as possible, *e.g.*, in the Taylor system. Great importance is attached to social work, and workers' representatives play an important part when questions were discussed, not only relating to wages, but also to the management of the works.

The general impression gained by Prof. Hauser was that the prosperity of the United States depended on the vast absorption capacity of the interior markets, so that the question of exportation was of secondary importance. But the acceleration of production could surpass this capacity of absorption, which has, so far, not been affected by the increases in wages. If the appreciation of the dollar continues to limit exportation, a renewed interest by the United States in European economic interests might not be impossible in the future.

ACADÉMIE DES SCIENCES

M. Friedel read a paper on November 26, on certain black inclusions in diamonds, the inclusions being shown to be lamellæ of graphite. At the end of the meeting, Prof. Aimé Cotton was elected a member of the physical section, in place of the late Prof. Violle.

On December 4, M. Jentil communicated a note by M. Lazareff, on magnetic anomalies in Russia, shown over two bands, 200 km. long and 50 km. apart, and due to the presence of iron. Iron ore has actually been discovered at a depth of 500 ft., the mineral containing 40 per cent. of iron, the percentage increasing in depth. The author claimed that this deposit was the largest yet found, as it was calculated to contain 16 times the total mass of iron of the rest of the world.

The Abbé Senderens described some researches on the catalytic dehydration of hydroaromatic alcohols, by means of which he has obtained little-known aromatic compounds.

M. d'Arsonval announced that the Cie. Générale d'Electro-ceramique had constructed a high-tension laboratory for research on currents of 1,000,000 volts.

On December 10, Monsieur Bigourdan communicated a paper by M. Henry, describing a self-registering thermo-electric actinometer, similar in principle to that of Arago, in which the difference in temperature between two black spheres placed in a vacuum is measured by means of a thermo-couple of great sensitivity.

Dr. Roux communicated a paper by MM. Girond and Durand of the Pasteur Institute, Tunis, on certain streptococci which produce colour when cultivated anærobically in the presence of starch.

Prof. Le Chatelier described work by Prof. Matignon, indicating that mono-sodium aluminate, zirconium silicate and aluminium nitride are worthy of consideration as refractory materials.

At the conclusion of the meeting, Monsieur Bigourdan was elected president, Monsieur L. Bouvier, vice-president for 1924, and MM. E. Picard and A. Lacroix were elected as perpetual secretaries.

From the Lontreuil Bequest 10,000 francs was awarded to the Central Electrical Laboratory of Paris for researches on the standard international ohm; 10,000 frs. to the international committee of tables of constants, and 5000 frs. to the Office Central de Chauffe Rationale, for work on the industrial measurement of high temperatures.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

A lecture entitled "From Test-tube to Tank Wagon in Three Years" was delivered by M. A. Appleyard, M.Sc., of Bristol University Fruit Research Station, at the meeting on December 3, Prof. G. T. Morgan, F.R.S., presiding.

After a summary account of the production of higher alcohols by fermentation, Mr. Appleyard discussed the cultural characteristics of the acetone organism with which he had carried out the Weizmann process in England and in India. The method of sub-culturing the organism, and the best way to secure a virile culture, were described. The mechanism of the reactions which take place when carbohydrate is fermented with the acetone organism was considered, and emphasis was laid on the necessity for further work on the question of the nitrogen nutrition of this bacillus.

The reasons for failures to ferment wort successfully in the early stages were attributed to the fact that sufficient protein was often absent from the wort. The importance of Dr. Thaysen's discovery of *Bacillus volutans* was commented upon, and a tribute was paid to the work of Dr. H. B. Hutchinson, Dr. A. C. Thaysen, Mr. F. Hirst, and Mr. A. Gill, B.Sc., who did a great deal to make the Weizmann process a success on a large scale. Experience indicates that the types of infection against which it is imperative to guard are those found on the grain itself, and success with the process is measured by the extent to which such infections can be destroyed or suppressed.

A description was given of the types of cookers, vats, stills most suitable for the process, and slides were shown illustrating various acetone plants in England, Canada and India. Owing to recent developments in America by the Commercial Solvents Corporation of New York, it was more appropriate now to refer to this process as the butyl alcohol process. A large number of butyl derivatives which are being used to a large extent in the United States were exhibited. The large development of the nitro-cellulose industry in the United States was referred to in some detail, and the steps taken by the Commercial Solvents Corporation of New York—the assignees of the Weizmann patents—to meet the needs of this industry were described. The United States can consume annually for known uses no less than 6000 tons of high boiling solvents; Germany consumes from 600 to 800 t.; whilst Great Britain requires about 400 to 500 t. a year. Probably about 80 per cent. of the butyl alcohol produced is converted into and used as butyl acetate, which is a satisfactory substitute for amyl acetate as a solvent of nitro-cellulose. Other uses are constantly being suggested, and there is little doubt that in a short time many butyl derivatives recently made available in large quantity will be found useful in industry.

INSTITUTION OF ELECTRICAL ENGINEERS

On December 13 a paper on "Pulverised Fuel and Efficient Steam Generation" was read by Mr. D. Brownlie, B.Sc., M.I.Chem.E.

The first mention of pulverised fuel dates as far back as 1820, and remarkable work was carried out by T. R. Crampton, of London, in 1868, but pulverised fuel was first used on a large scale in the cement industry, especially in the United States, shortly after 1890, and to-day about 90 per cent. of the cement of the world is made with pulverised coal. The present total consumption of pulverised coal for all purposes in the United States and Canada, but particularly in the cement, iron and steel, and glass industries, is now over 30 million t. per annum. Little progress was made in application to steam generation in the United States until 1913, the real development commencing in 1920 with the Lakeside plant at Milwaukee. The general principles of the process consist in crushing the coal, passing it over a magnetic separator to remove iron, drying down to 1–2 per cent. moisture, and pulverising in ball mills so that 90 per cent. will pass through a 100-mesh screen (100 holes per linear in.) and 65 per cent. through a 200-mesh screen. The pulverised coal is conveyed to bunkers, and then to "feeders," which mix the coal with 10 per cent. of the air required for combustion and deliver it to the burners, in which 90 per cent. of the air, preheated to a high temperature, is then added. The result is an intensely hot flame of over 2000° F. with complete combustion, 17–18 per cent. carbon dioxide and entire absence of smoke.

The "Lopulco" system of pulverised fuel embodies many improvements, the chief being the water screen (a series of water-cooled 4-in. steel tubes in the bottom of the furnace), which prevents the ash becoming molten. Further, cold air circulating through the hollow brickwork becomes heated to 300-700° F., and is used to supply the 90 per cent. of secondary air to the burners. The average efficiency with which 90 million t. of coal is burnt per annum in the steam boilers of Great Britain is less than 60 per cent., representing an avoidable loss to the country of 20 million t. of coal per annum. In Great Britain, apart from three small installations, only one large boiler plant, that of the Hammersmith Electricity Station, uses pulverised coal.

The advantages of pulverised coal include:—Higher boiler-plant efficiency; complete combustion of the ash; the fuel is free from moisture; convenient of transport in the boiler house; flexibility of the steam output of the boiler, permitting overloads of 100 per cent. for long periods; reduced stand-by and banking losses; greater ease of scientific control; and reduced labour costs. The various disadvantages, such as excessive power consumption, wear and tear and risk of breakdowns; danger of explosion and spontaneous combustion; troubles with the ash; and higher capital cost as compared with mechanical stoking, are now proved, as the result of experience, to be almost entirely avoidable.

Extraordinary efficiencies are obtained with pulverised coal. Lakeside is running regularly at 85–86 per cent. boiler plant efficiency, and 89 per cent. has been obtained on ordinary short tests. The loss of heat in the chimney base is only 8 per cent. Labour costs with pulverised coal are approximately 20 per cent. less than with mechanical stoking; and the unburnt material in the ash of pulverised coal is 0·40–0·75 per cent. carbon, whereas the best stoker figures are 2 per cent. with 3–5 per cent. for a large number of stations.

The quality of the coal that can be burnt varies enormously, so that differences in the heating value do not affect the efficiency of the plant, on the contrary, to mechanical stoking. It is difficult to obtain authentic figures for the capital cost, but roughly there is not much difference between pulverised coal and mechanical stoking.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held at the Offices of the Association on December 13, 1923, Sir Max Muspratt presiding.

The Council extended its congratulations to Sir William Alexander, Sir John Brunner and Dr. G. C. Clayton on their election as Members of Parliament.

Dr. A. Ree presented a report of a conference which had been arranged by the Trade Marks, Patent and Designs Federation to consider the International Industrial Property Convention of 1883, which regulates international relations in industrial property matters and which is due to be revised in the near future. It appears that at the conference certain resolutions were passed including one recommending the abolition of revocation of patent rights either for non-working or for abuse of monopoly rights, but permitting each country at its discretion to grant compulsory licences in such cases. Another resolution was opposed to a proposal as to the desirability that the laws of the Convention Countries should contain an uniform clause providing that no patent be granted in respect of:—(*a*) Products resulting from the combination of defined chemical elements; (*b*) pharmaceutical products; or (*c*) patent medicines of all kinds. The Council was strongly opposed to these recommendations and the General Manager was instructed to convey this decision to the Trade Marks, Patents and Designs Federation.

In connexion with the British Empire Exhibition the General Manager reported that a contract had been entered into with Messrs. Gaze & Sons, Ltd., for the erection of the shell stands in the Chemical Section.

A report from the Transport Manager indicated that the conditions of carriage of merchandise by merchandise train at owners' risk had been approved by the Railway Rates Tribunal after being agreed between the railways and the traders' representatives. The question of the retention of exceptional rates in accordance with Section 36 of the Railways Act, 1921, has also been the subject of negotiation with the railway companies and it is hoped to be able to announce a definite settlement of a scheme to deal with the matter at the end of the present week.

CORRESPONDENCE

COLOUR EFFECTS

Sir,—Referring to the extremely interesting article by Mr. Rex Furness in your issue of November 23, it seems to me that he overworks the words "disperse" and "dispersion" in connexion with colour effects. Why disregard the old doctrine of interference, as, for instance, in the case of "Newton's rings," and the colours of the peacock and of selective absorption as in the case of atmospheric effects?

Spectrally, a blue sky is simply a minus yellow. The spectrum gives every colour in the rainbow, but a comparative dimness in the yellow. In other words, not the normal amount of yellow light. Now, in a transparent or partially transparent medium like the air, it is inevitable that the same medium that reflects one colour from white light should show the complement of that colour to an observer looking at the course of the light through the medium. For instance, in the evening, the prevailing colour on the side away from the sun is bluish and on the side toward the sun yellowish or reddish. Nevertheless, these tints are modified by the actual absorption of a certain amount of light, but generally speaking, white light is analytically divided: part of it is reflected and part transmitted.

In connexion with the subject of camouflage and in particular of concealed insignia at the time of the world war, I made some study of pigments and dyes and found three things:—

First, natural colours are never monochromatic.

Second, pigments are never monochromatic although some, as for instance ultramarine, are quite nearly so. By ultramarine I mean the artificial lapis lazuli.

Third, synthetic dyes are more nearly monochromatic than natural colours. They show practically a total absence of certain parts of the spectrum and by a very careful study and selection of dyes and of colour screens, determined by actual spectrum analysis of both, very interesting and extraordinary effects can be obtained.

I was shown in the laboratory of Mr. Pevear, the colour expert who arranged the colour effects in the great celebration of the Massachusetts Institute of Technology in the year 1917, three yellows indistinguishable by the naked eye, of which one was simply a minus violet, showing every colour in the spectrum excepting violet ; another was a monochromatic yellow; and the other contained no yellow, but was simply a mixture of blue and green. I was shown at the Bureau of Standards in Washington a brilliant canary yellow shade of paper on which, to the naked eye, there was not the slightest trace of any marking of any kind or sort, and on looking at it through a yellow colour screen writing appeared as black as ebony.—I am, Sir, etc.,

Godfrey L. Cabot

Boston, Massachusetts
Dec. 7, 1923

TURKEY RED OIL

Sir,—I should be obliged if any of your readers would give me any information regarding "Turkey Red Oil," its price and where it is obtainable.—I am, Sir, etc.,

R. J. C.

Dec., 16, 1923

PERSONALIA

Monsieur Mailag has been appointed professor of industrial chemistry, and Monsieur Calerns, professor of agricultural chemistry in the University of Toulouse.

The Royal Academy has formed a committee of artists and scientists to investigate the qualities of artists' materials and the various methods of cleaning old pictures. The committee includes the following scientific members : Prof. A. P. Laurie, Sir H. Jackson, F.R.S., Sir A. Schuster, F.R.S., Dr. A. Scott, F.R.S., Mr. C. F. Cross, F.R.S., Dr. R. S. Morrell and Mr. N. Heaton.

* * *

We regret to announce the death, on December 18, of Prof. F. Clowes, at the age of eighty-five. Prof. Clowes occupied the chair of chemistry at University College, Nottingham, from 1881 to 1897, when he became chemical adviser to the London County Council, and since 1913 he had been expert adviser on gas supply to the Corporation of London. He was President of the Society of Chemical Industry in 1897–1898, a vice-president of the Institute of Chemistry, and an active member of other scientific bodies. He was the author of standard textbooks on analytical chemistry, and published a number of investigations bearing on analysis, the bacterial treatment of sewage, and the estimation of gases in the air.

NEWS AND NOTES

BRITISH INDIA

Second Forecast of the Sesamum Crop, 1923-24

According to reports received from provinces which contain an average of 99·6 per cent. of the total area under sesamum, the area so far reported under the crop is 3,016,000 acres, as compared with 3,432,000 acres at this time last year, a decrease of 12 per cent. The present condition and prospects of the crop are, on the whole, reported to be fair.—(*Ind. Tr. J., Oct.* 25, 1923.)

Second Forecast of the Sugar-cane Crop, 1923-24

The area planted to sugar-cane in provinces which contain on an average 99 per cent. of the total area under sugar-cane, is estimated at 2,787,000 acres, as compared with 2,460,000 acres at this time last year, an increase of 13 per cent. The weather has not been unfavourable to the crop, and present prospects, on the whole, are satisfactory.—(*Ind. Tr. J., Oct.* 25, 1923.)

CANADA

Pulp and Paper Industry

There were 104 pulp and paper mills in operation in Canada in 1922, the total net value of the production being $155,785,388, according to a preliminary report issued by the Dominion Bureau of Statistics. The amount of capital invested in the industry increased from $379,812,751 in 1921 to $381,006,324 in 1922. The number of employees in the pulp and paper industry in 1922 was 25,830, whilst wages and salaries amounted to $32,918,955. More than 50 per cent. of the exports of pulp. wood was supplied by the Province of Quebec.

UNITED STATES

The Use of Glue in Coating Paper

The Bureau of Standards is carrying out some experiments dealing with the use of glue in coating paper. Nine runs have been made on the experimental coating machine, using two makes of bone glue for eight of the runs and a French casein glue for one. A good grade of English coating clay (Lee Moor) was used for all runs, and the results indicate that the water resistance of glue-bound coating containing chrome alum, compares favourably with that of casein-bound paper containing no formaldehyde. It is believed that the degree of waterproofness will prove sufficient for most of the papers used in half-tone printing. Difficulties have been experienced in obtaining a uniform coating, because of variation of the fluidity of the coating mixture, and mechanical defects in the machine, so that additional work will be necessary before paper suitable for printing tests can be produced.—(*Chem. & Met. Eng., Oct.* 22, 1923.)

REVIEWS

Motor Fuels, their Production and Technology. *By* E. H. Leslie, Ph.D. *Pp.* 681. *New York: Chemical Catalog Co., Inc.*, 1923. *Price* $7.

To the many books dealing with petroleum, published during the last few years, particularly in the United States, that under review is certainly an important addition.

The author, Dr. Leslie, fully explains his aim and objects in an excellent preface. A study of the book will demonstrate how well these have been achieved. Perhaps the most striking feature of the book is the critical attitude adopted by the author. Realising that "the tendency of the human mind is to travel in ruts" and that "too often much ingenuity is extended in trying to perfect an apparatus which is inherently incorrect," he points out the necessity for an accurate knowledge of the underlying principles of physics, thermodynamics and chemistry. In the chapters dealing with plant construction and operation, he points out the application of these principles, exemplifying this by the critical study of actual plants.

The book opens with an introductory chapter in which the development of the petroleum industry and the problem of future supplies of motor fuel are briefly discussed. This is followed by a chapter on the composition of petroleum, which, however, deals practically only with the crudes of the Western hemisphere, many interesting types of crudes of the Old World receiving no mention.

Chapter III gives a short summary of the working-up of crude oils in the refinery, which is quite sufficient for the purposes of the book.

Chapters IV to VII deal with the manufacture of motor fuels, the principles of the theory of fractional distillation and their applications being fully discussed. The application of the laws of fluid flow and heat transfer to the refining plant is also well treated, the difficulty of the subject being fully recognised.

The chapter on refinery equipment is very good, the modern types of plants are described, and important practical details dealt with. His condemnation, "Distillation equipment now in general use in the petroleum industry can hardly be said to be better than crude," is too often well merited.

An interesting chapter on the thermal reaction of hydrocarbons leads up to a description of the chief cracking processes which have actually been in use.

The question of the chemical refining of gasoline is fully discussed and the modern methods of refining, such as the Edeleanu, silica gel and hypochlorite processes are described.

A chapter on the natural gas industry concludes the portion of the book which deals specifically with petroleum products.

In a short chapter the production and manufacture of alcohol and its possibilities as a motor fuel are discussed. This is followed by a short chapter on the more interesting of the composite motor fuels, such as Natalite and Alcogas.

The latter quarter of the book deals with specifications, methods of analysis, with tables of useful data, constants, etc.

As specifications are liable to change from time to time and as these and the methods of analysis are so readily accessible in the publications of the "United States Bureau of Mines," of the American Society for Testing Materials, etc., the chapters dealing with these form the least valuable portion of the book. As many of the data given in Chapter XVII, however, are not readily available elsewhere, this chapter is one of considerable value.

On the whole the book confines itself rather to American practice and American oils. It is up to date and includes most modern work of interest. It is a pity that a section was not devoted to the use of motor fuels and the behaviour of the various types of hydrocarbons and other fuels in the automobile engine. No mention is made of the important work of H. Ricardo in this connexion published in the *Automobile Engineer* in 1921. The book is well printed and the copious references to the literature of the subject should prove very useful. It is certainly one of the most useful books that the reviewer has come across, and the author is to be congratulated on the mass of useful information contained therein, and on the way in which the subject is handled.

J. Kewley

Coke and Its Uses, in Relation to Smoke Prevention and Fuel Economy. *By* E. W. L. Nicol. *Pp. xii*+132. *London : E. Benn Bros., Ltd.*, 1923. *Price* 19*s*. 6*d*.

This is a somewhat short treatise in non-technical language, dealing with the use of coke, particularly from the point of view of steam and power generation (other than gas producers), being essentially a plea for the use of coke instead of raw coal. Mr. Nicol, who, as is well known, is the engineer and fuel expert to the London Coke Committee, is naturally an enthusiast on the subject, but in view of his long and specialised experience very few people indeed are better qualified to write a book of this character.

For steam generation, coke, provided the moisture content is not over, say, 7-8 per cent., is a most excellent fuel, and Mr. Nicol states the general advantages concisely and without exaggeration. In fact, more might be made of this aspect ; thus, for example, coke as a rule gives a granular ash which consequently is easy to clean out. Some of the prejudices that still exist against the use of coke, such as that it corrodes boilers, and "has had all the nature taken out of it," are dealt with trenchantly

In this connexion Mr. Nicol states that prior to 1913 the use of gas coke as fuel for steam raising was practically unknown outside the gas industries, which is rather a neat, and presumably unconscious, commentary on the characteristic lack of enterprise and imagination displayed by the gas industry in the matter. During the past century millions of tons of coke breeze have been simply thrown away, and apparently millions of tons of gas coke sold at a price much below their true value, for want of organisations such as the London Coke Committee, which was only founded ten years ago. A considerable space is, quite rightly, devoted to the "sandwich" system for burning coke and coal, and although this is generally applied to chain-grate stokers, it is interesting to learn the same principle will work with the "Underfeed Type E" stoker. Unquestionably we shall have to devote more attention to the efficient burning of refuse fuels in these hard times, and mounds of coke breeze are one of the best arguments for a more progressive policy on the part of the steam user in general.

Mr. Nicol does not discuss the most serious objection to coke, the varying moisture content, and as far as can be made out all his comparisons with coal are based on coke of 12,000 B.Th.U., and 5 per cent. moisture. To anyone who has had much practical experience of coke this seems hardly fair, and whilst for example with dry coke 9½ lbs. of water can be evaporated per lb. of coke, the consumption being 20 lbs. per square foot of grate area per hour, most commercial coke will not do this. The book is extremely well printed on excellent paper, and the illustrations are adequate, but it somehow gives the impression of being "skimpy," and the index could be improved.

David Brownlie

COMPANY NEWS

THE BRITISH CYANIDES CO., LTD.

The directors take advantage of the opportunity afforded by the payment of the preference dividend to give shareholders a brief account of the company's progress. At the annual general meeting in July last, the chairman stated that an interim dividend on the ordinary shares would be considered before the end of the year, subject to the proviso that the conditions of trade did not depart from the normal to any great extent. Unfortunately, conditions have been by no means normal since then, and the directors, therefore, do not feel justified in declaring a dividend. The plant for the manufacture of permanganate of potash was started up last August and is earning revenue. The first unit plant for the fixation of atmospheric nitrogen, mentioned at the annual meeting, has been installed and was started up in November. The process is producing and promises well, and further units are being installed.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for Dec.* 13)

OPENINGS FOR BRITISH TRADE

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Aden ..	Photographic accessories	630
Australia ..	Hardware, crockery ..	631
,, ..	Tinplate, crockery, hardware, glassware, building materials	631 *
,, ..	Engineering supplies, builders' requisites	412/7/1/1/189
Belgium ..	China, crystal glass, earthenware	**
Canada ..	Liquid chlorine ..	12639/E.D./E.C./2
Egypt ..	Paint, oil (tender) ..	11944/F.E./C.C.

** The Belgian Chamber of Commerce, 24, St. Dunstan's Buildings, St. Dunstan's Hill, E.C. 3.

TARIFF CUSTOMS EXCISE

Australia.—The application of the duty on metal cordage, paper, and iron and steel has been further postponed.

Bulgaria.—Imports of artificial fertilisers are allowed duty-free.

Italy-Spain.—Reduced duties are prescribed for Spanish citric and tartaric acid and rubber imported into Italy, and for Italian fish oil and skins imported into Spain.

Poland.—A list is given in the current issue of reduced duties on certain articles imported from the United Kingdom.

Rumania.—The import duty on rubber goods is increased.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains a steady tone, both home trade and export continuing to take tolerably satisfactory quantities. Prices are firm.

Acetic Acid. 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder ..	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d.—6d. per lb.
Potass. Chlorate ..	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide ..	4s. 9d. per lb.
Carbon Bisulphide ..	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide ..	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark ..	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite ..	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal. Naphthas are an unsettled market.

Acetate of Lime—	
Brown	£14—£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor..	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.-1s. ,, ,, 14/15° Tw.
Wood Creosote	2s. 7d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Competition being met with.
Solvent	6s. per gall. 40% O.P. Fair demand.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead ..	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. per lb. Weaker, with limited demand.
Crude 60's	2s. 9d.—3s per gall. Little business passing.
Acid Cresylic, 97/99 ..	2s.—2s. 1d. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall. A little inquiry for forward delivery.
Anthracene Paste 40%..	4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—	
Strained	9d.—10d. per gall. Better demand. Little material available.
Unstrained	8d.—9d. per gall. Quiet.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil	8½d.—9½d. per gall. according to grade and district. Market very firm.
Heavy	
Standard Specification	
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 1d.—1s. 2d. per gall. Market weak.
Solvent 90/190	1s. 1d.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 per ton.
Flaked	£19 per ton.
Pitch, medium soft	100s.—105s. per ton. Rather more inquiry, but little business passing.
Pyridine—90/140	22s.—23s. per gall. Demand easier.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 7d. lb. 100% basis d/d.
Acid Naphthionic	2s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—10d. per lb. naked at works.
Aniline Salts	9½d.—10d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 7d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 6d. per lb. d/d. Drums extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 6d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. lb. 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s.—4s. 6d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The demand is falling off as the end of the year approaches, but further appreciation in prices may be expected after the holiday period.

Acid, Acetic 80% B.P.	£48 10s. per ton.
Acid, Acetyl Salicylic	3s. 7d.—3s. 9d. per lb. Price hardening. Some makers asking 4s. In very steady demand.
Acid, Benzoic	B.P. quality almost unobtainable. Commercial quality offered forward at 2s. 3d. per lb. for cwt. lots. Makers fully sold ahead.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5%, for ton lots. Dearer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d.—2s. 7d. per lb. Very firm market. Makers hard pressed to meet demand.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Firmer. More inquiry for forward delivery.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 3s. 6d. per lb. on a short market.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. 3d.—5s. per lb. for English make. Cheaper than other benzoates.
Ammon. Carbonate B.P.	£27 15s. per ton.

Atropine Sulphate	12s. 6d. per oz. for English make. Dull market.
Barbitone	18s. per lb. Without much inquiry.
Benzonaphthol	6s. per lb. Very much firmer.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9d.—10d. Remain very firm. Continental prices advancing.
Sodium	9½d.—10d.
Ammonium	10d.—11d.
Calcium Lactate	2s. 9d. per lb. for best English make. A better market.
Chloral Hydrate	4s. 3d. per lb. Position very firm and active.
Chloroform	2s. per lb. for cwt. lots. More active.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 14s. per lb.
Hexamine	4s. 6d. per lb. for foreign makes. Manufacture in England has been discontinued since formaldehyde was removed from the dutiable list.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£72 10s. per ton, less 2½%.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 62s. 6d. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	3s. per lb. for carboys. Brisk market. Slightly advanced.
Methyl Sulphonal	22s. per lb.
Methylene di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 7d. per lb.
Phenacetin	7s. 6d. per lb. Steady market. English makers fully employed. Foreign supplies shorter.
Phenazone	8s. 9d. per lb. In short supply.
Phenolphthalein	8s. 6d. per lb. Very firm.
Potass. Bitartrate—99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Permanganate	9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d.—5s. 9d. per lb. Neglected.
Salol	4s. per lb. In more plentiful supply.
Silver proteinate	10s. 6d. per lb. Quiet.
Sod. Benzoate	3s. 6d. per lb. Scarce.
Sod. Citrate, B.P.C., 1923	1s. 5d.—1s. 9d. per lb., according to quantity. Very firm, in common with other citrates.
Sod. Hyposulphite— Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 11d. per lb., and Crystal at 3s. per lb. Firm and very active. Supplies still scarce.
Sod. Sulphide— Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	4s. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	10s. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s to 13s. 6d. per lb.
Heliotropine	8s. 6d. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	20s. ,, ,,

Linalyl Acetate ..	.. 20s. ,, ,,
Methyl Anthranilate	.. 8s. 6d. ,, ,,
Methyl Benzoate	.. 6s. ,, ,,
Musk Ketone ..	.. 52s. 6d. ,, ,,
Musk Xylol ..	.. 19s. ,, ,,
Nerolin	.. 4s. ,, ,,
Phenyl Ethyl Acetate	.. 10s. ,, ,,
Phenyl Ethyl Alcohol	.. 16s. ,, ,,
Rhodinol.. ..	.. 60s. ,, ,,
Safrol	.. 1s. 10d. ,, ,,
Terpineol ..	.. 3s. ,, ,,
Vanillin	.. 25s. 3d.—26s. 6d. per lb. Firm with steady demand. Raw materials dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 14s. 6d. per lb.
Anise Oil.. ..	.. 1s. 11d. ,, ,,
Bergamot Oil ..	.. 13s. 3d. ,, ,, spot.
Bourbon Geranium Oil	.. 37s. ,, ,,
Camphor Oil ..	.. 75s. per cwt.
Cananga Oil, Java	.. 9s. 6d. per lb.
Cinnamon Oil, Leaf	.. 5¾d. per oz.
Cassia Oil 80/85%	.. 11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	.. 4s. 9d. ,, ,,
Ceylon.. ..	.. Very little on offer.
Clove Oil.. ..	.. 10s. 6d. per lb.
Eucalyptus Oil 70/75%	.. 2s. 6d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil ..	.. 2s. 10d. per lb. Higher prices expected.
Lemongrass Oil ..	.. 2¾d. per oz.
Orange Oil, Sweet	.. 11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 34s. per oz.
Anatolian ..	.. 26s. per oz.
Palma Rosa Oil	.. 24s. 6d. per lb.
Peppermint Oil—	
English ..	.. 70s. per lb. Market very unsteady.
Wayne County	.. 15s. 6d. per lb. Market very unsteady.
Japanese ..	.. 12s. 6d. per lb. Market very unsteady.
Petitgrain Oil ..	.. 9s. 6d. per lb. Dearer.

TRADE NOTES

Exhibition of Educational Materials in Argentina

The Department of Overseas Trade is informed by the British Legation at Buenos Aires that the American Academy of History is organising an International Congress of History and Geography of America and exhibition of educational materials to be held in Buenos Aires in 1924.

The Academy invites all scientific and geographical institutions to participate, as well as manufacturers of and dealers in materials concerned in the supply of educational institutions, libraries, science laboratories, etc. Particulars of the scheme may be obtained from the Secretary of the Academy, Dr. A. E. de la Guardia, Academia Americana de la Historia, Buenos Aires.

Market News from Belgium

Prices of iron and steel products have a downward tendency, but the situation is uncertain. There are no signs of a fall in the price of coal, as there are no stocks at the mines, and importation is hindered by the appreciation of sterling. Coke is in very short supply. The situation in the plate-glass industry is excellent, and all the works are in full production. Window glass is in good demand, and orders have even been refused. Prices for bottles are very firm. There is a good demand for cement.

The British Fertiliser Industry

The report of the British Sulphate of Ammonia Federation for the year ending May 31, 1923, states that production increased by 50 per cent., exports by 58 per cent., and home deliveries by 3 per cent., as compared with the previous year. Exports were satisfactory during the last six months, although prices have declined. Many of the Canadian producers have joined the Federation.

The superphosphate industry continues to suffer from Continental competition, and several large factories have been closed for some months. Competition is felt chiefly from French, Belgian and Dutch makers.—(*Bull. F. B. I., Dec.* 4, 1923.)

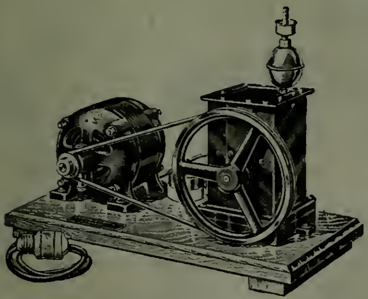
London Depot: **28, Victoria Street, S.W. 1.**

The Cenco
HYVAC PUMP
For producing a Vacuum of 0·001 mm. without Backing Pump

Is Proving Very Popular in Canada and the United States

(Canadian Representative: J. H. Wilson, Toronto)



No. 10999

(Kindly Specify Voltage Available when Ordering.)

¶ It fills the requirement of unfailing support for mercury vapor pumps of all types. This is not true of pumps which will give a vacuum not better than 0.01 mm.

¶ It is so constructed that the freedom of wear of the working parts will insure long life with no visible diminishing of its original characteristics.

¶ IT IS NOISELESS IN OPERATION. This is a valuable feature not only for lecture table demonstration but for laboratory or research department where a loud grinding, clicking or buzzing sound is a strain on the nerves.

Prices F.O.B. New York
(Including Export Boxing)

No. 10996 (without Motor) - $52.00
No. 10999 (with Motor) - $95.00

Refrigerating & Ice Making Plants

World-wide experience—

No. 2 London.

This plant installed by us for Messrs. Harrods deals with the storage of meat, fish, poultry and game, and the production of ice. There are also separate machines for cooling rooms, for the storage of furs and for the chocolate and restaurant departments.

The plant is giving complete satisfaction, due to the careful preliminary discussion as to requirements and local conditions to be met.

We invite you, therefore, if you are considering ice-making plants or refrigeration machinery in any part of the world, to send for our catalogue and to discuss the matter with us.

Forty-five years' experience of refrigeration and 135 years of general engineering.

THE CHEMIST
PREFERS
DUROSIL

The new and improved laboratory glass of high thermal endurance and chemical resistance.

BEAKERS, FLASKS, BASINS, TEST TUBES, etc., of the finest quality.

DUROSIL Round Bottom Basins may be used for evaporation to dryness over a bare flame.

For all laboratory purposes requiring agitation or cooling, particulars should be obtained of the Hickman Circulators and Agitator.

Wm. JOHNSON & SONS
ARMLEY, LEEDS. (LEEDS), LTD.

Established 1860.

Engineers and Original Makers of Ball Mills, Tube-Mills, etc., for Fine Grinding.

CHEMICAL WORKS PLANT.

Machinery Specially Designed and Built to Suit your Particular Duty.

SPECIALITIES:
Chemical Works Machinery Generally.
Crushing, Grinding, Screening and Drying Plant for any Material.
Washing and Levigating Tanks.
Wet or Dry Mixers, Blenders, &c.
Cement and Plaster Plant.
Elevators, Conveyers, Feeders and Distributors.
Roasting and Calcining Plant.
Brick, Block and Briquette Machinery.

OUR LATEST IMPROVED COMBINED BALL - TUBE MILL produces in one unit the FINEST POWDERS or SLIMES from rough material without the use of sieves or separators.

NATIONAL SCHEME FOR DISABLED MEN

THE BRITISH ENGINEERS' ASSOCIATION B E A

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND

EXAMINATIONS for the Associateship and Fellowship are held in January, April, and July. Application forms may be obtained from the Registrar. Other particulars will be forwarded to Candidates whose applications are accepted by the Council, and who intend to present themselves.

REGULATIONS for the admission of Students, Associates and Fellows: Gratis.

APPOINTMENTS REGISTER.—A Register of Chemists who are available for appointments is kept at the Office of the Institute. The facilities afforded by this Register are available to Companies and Firms requiring the services of Analytical, Research, and Technological Chemists, and to Universities, Colleges, Technical Schools, &c., requiring Teachers of Chemistry and Technology.

All communications to be addressed to the Registrar, The Institute of Chemistry, 30, Russell Square, London, W.C. 1.

Spectrographic Analysis

Infinitely small traces of Metallic elements—even beyond detection by chemical methods—are easily recorded by Spectrography.

PRINCIPLES OF CHEMICAL ENGINEERING

By

William H. Walker, Warren K. Lewis, and William H. McAdams,

Professors of Chemical Engineering, Massachusetts Institute of Technology.

624 pages, 6 x 9, 156 illustrations.

Price 25s. net.

The book presents the principles of stoichiometry, describes the phenomena accompanying the flow of heat and the flow of fluids, together with the laws governing these operations, discusses fuels and their efficient combustion, and treats the processes of crushing and grinding, mechanical methods for separating materials, filtration, and the processes depending upon vaporization.

CONTENTS.—I.—Elements of Industrial Stoichiometry. II.—Fluid Films. III.—Flow of Fluids. IV.—Flow of Heat. V.—Fuels and Power.—VI.—Combustion. VII.—Furnaces and Kilns. VIII.—Gas Producers. IX.—Crushing and Grinding. X.—Mechanical Separation. XI.—Filtration. XII.—Basic Principles of Vaporization Processes. XIII.—Evaporation. XIV.—Humidity and Wet and Dry Bulb Thermometry. XV.—Humidifiers, Dehumidifiers and Water Coolers. XVI.—Drying. XVII.—Distillation.

PATENTS.

THE PROPRIETORS OF THE PATENTS
No. 174,041, Improvements in or relating to apparatus for the synthesis of ammonia ;
No. 130,086*, Process of effecting exothermic chemical synthesis taking place under pressure and at a high temperature ;
No. 129,637, Method of purifying the gases intended for the synthetic production of ammonia ;
No. 130,365, Process for the conversion of synthetic ammonia into a solid product applicable for agricultural purposes in conjunction with the production of carbonate of soda ;
No. 142,150, Apparatus for the synthesis of ammonia at very high pressures ;
No. 150,744, Improvements in or relating to processes and apparatus for the direct synthesis of ammonia ;
No. 153,254, Improvements in or relating to catalytic materials adapted for use in the synthesis of ammonia ;
No. 160,172, Improvements in or relating to processes for the production of bicarbonate of soda and ammonium chloride ;
No. 160,811, Improvements in or relating to the synthesis of ammonia ;
No. 161,195, Improvements in or relating to the synthesis of ammonia ;
No. 171,970, Improvements in or relating to the synthesis of ammonia ;
No. 171.972, Improvements in or relating to the synthesis of ammonia ;
No. 175,958, Improvements in or relating to devices for the withdrawal of liquids under gaseous pressure ;
No. 177,494, Improvements in or relating to the synthesis of ammonia by means of hyper-pressures ;
No. 177,777, Improvements in or relating to the synthesis of ammonia by means of hyper-pressures ;
are desirous of entering into arrangements by way of licence and otherwise on reasonable terms for the purpose of exploiting the same and ensuring their full development and practical working in this country. —All communications should be addressed in the first instance to HASELTINE, LAKE AND Co., Chartered Patent Agents, 28, Southampton Buildings, Chancery Lane, London, W.C. 2.

SITUATIONS WANTED.

HONOURSMAN, with 20 years' manufacturing experience, can give part-time services in London area.—Box 215, Willing's, King's Cross, London, W.C. 1.

MISCELLANEOUS SALES.

HALL'S No. 4 CO, REFRIGERATOR. COPPER JACKETED PAN, 2 ft. 6 ins. diameter by 2 ft. deep, tilting. Werner Pfleiderer Mixer, about 40 gallons capacity.—Gardams, Engineers, Staines.

FOR SALE, Journal of the Society of Chemical Industry, complete from 1882 to date; all bound but last 6 volumes.—Offers to Box 909, c/o The Society of Chemical Industry, 46, Finsbury Square, E.C. 2.

Very Low Price for Quantities. Enquiries Invited. Apply Box No. 872, c/o Society of Chemical Industry, 46, Finsbury Square, London, E.C. 2.

SOCIETY OF CHEMICAL INDUSTRY

CENTRAL HOUSE,
FINSBURY SQUARE,
LONDON, E.C.2.

PUBLICATIONS

THE JOURNAL OF THE SOCIETY :—

Consisting of Chemistry and Industry, Transactions and Abstracts in Applied Chemistry issued weekly on Fridays during the year. To non-members of the Society £4 4s., post free, to any part of the world. Extra copies to members of the Society, £2 10s., also post free. Single numbers 1s. 9d., postage extra.

CHEMISTRY AND INDUSTRY :—

Issued as a separate publication, under the title of Chemistry and Industry Review, weekly on Fridays during the year. Annual Subscription £1 1s. (Home), £1 5s. (Overseas). Single numbers 6d., postage extra.

ABSTRACTS IN APPLIED CHEMISTRY :—

Published weekly, on Fridays, during the year, are supplied (under a reciprocal arrangement) to Fellows of the Chemical Society who are not members of the Society of Chemical Industry, at an Annual Subscription of £1 10s., post free.

Members of the Society can, for the Annual Subscription of £1, receive the weekly issues of these Abstracts, *printed on one side of the page only*, to facilitate filing for reference.

BACK NUMBERS OF THE JOURNAL :—

The Society has a considerable stock of back numbers of the Journal from 1882 onwards, although many of the issues are out of print. Inquiries for back numbers should be sent to the General Secretary, who will quote prices for them.

DECENNIAL AND COLLECTIVE INDEXES :—

The Society has still a stock of the Collective Index to the Journal, Vols. 1-14 (1882-95), and of the Decennial Index comprising Vols. 15-24 (1896-1905). The prices of these are 5s. 6d. and 7s. 6d. respectively, post free.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY :—

Vols. 1 to 7 of these Reports have been published, and Vol. 8, covering the year 1923, will, it is hoped, be ready about the month of March, 1924. Vol. I. has long been out of print, but copies of the other volumes 2, 3, 4, 5, 6 and 7 can be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d. and 7s. 6d. respectively, and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d. and 12s. 6d. respectively. The price of Vol. 8 to members and non-members will be 7s. 6d. and 12s. 6d. respectively. If volumes 2, 3, 4, 5, 6 and 7 are ordered at the same time as Vol. 8, the set may be obtained by members for £2 2s. 6d. and by non-members for £3 15s. The books are sent to purchasers post free, and all orders (accompanied by the appropriate remittance) should be sent to the General Secretary of the Society at the above address.

B.D.H. FINE CHEMICALS

BRITISH MANUFACTURE.

The Fine Chemicals supplied under the above Trade Mark are of guaranteed purity. Analytical data of the B.D.H. products, including melting points, boiling ranges, and other purity criteria of all organic substances, will be supplied on request.

Ask for our Catalogue comprising 3000 *Reagents for Research and Analysis.*

WHY NOT TRY ADAMANTINE

H.B.H. BLUE BRICKS

for paving the floors of your factories?

They are hard, tough and durable; they stand fire and acid and alkalies.

CHAS. DAVISON & CO., LD., BUCKLEY, CHESTER. (1)

FILTER-CEL CAKE

FILTER-CEL

(Registered Trade Mark)

Any filterable liquid can be improved with Filter-Cel, and cloudiness does not develop with standing. Used with all types of pressure filters, it simplifies filtration, securing an increased rate of flow, longer cycles, greater production.

Filter-Cel is an inert mineral powder, neither alkaline nor acid. A small percentage mixed with the liquors prior to filtration entrains the finest particles of suspended matter, resulting in an absolutely clear filtrate.

Write us what products you filter and we will send without cost or obligation complete filtration data, together with a sufficient quantity of Filter-Cel for testing. Stocks at London and Liverpool.

Write for Bulletin B.40.

INDISPENSABLE BOOKS

GENERAL CHEMISTRY
An Elementary Survey emphasizing Industrial Applications of Fundamental Principles.
By HORACE G. DEMING.

A thoroughly modern text-book presenting an outline of all topics covered by modern chemistry, such as the Electron Theory, Hydrogen Ion Concentration, the Structure of the Atom, the recent developments in Colloid Chemistry, and Synthetics. Indispensable to anyone requiring a clear outline of the tendency of present-day developments.

616 pages. Med. 8vo. Fully illustrated.
Price **17s. 6d.** net.

PHARMACEUTICAL AND FOOD ANALYSIS
A Manual of Standard Methods for the Analysis of Oils, Fats and Waxes and Substances in Which They Exist; together with Allied Products.
By AZOR THURSTON.

This volume is the outgrowth of a long and intensely practical experience. It will admirably cover the requirements of chemists engaged in the analysis of foods and drugs, as the author has included, besides his own knowledge, the very essence of all that others know on the subjects treated.

429 pages. Illustrated. Med. 8vo.
Price **21s.** net.

FOOD INSPECTION AND ANALYSIS
By ALBERT E. LEACH & A. L. WINTON.

The work has been thoroughly revised and enlarged. Much new matter on the constituents of food, numerous analyses, and recent analytical methods have been incorporated.

1090 pages. 160 figures.
Price **42s. 6d.** net.

DETAILED PROSPECTUSES
"C. 9"
FREE ON REQUEST.

CHEMISTRY AND ANALYSIS OF DRUGS AND MEDICINES
By H. C. FULLER.

Fills a want long felt by chemists and pharmacists for a compilation of analytical methods, both qualitative and quantitative, covering the field of drug and medicinal chemistry.

1072 pages. Fully illustrated.
Price **50s.** net.

A GERMAN-ENGLISH DICTIONARY FOR CHEMISTS
By AUSTIN M. PATTERSON, Ph.D.

Contains over 30,000 definitions. It includes terms from all branches of Chemistry and the various chemical industries, and such terms from allied sciences as are likely to appear in chemical literature.

332 pages. Flexible binding.
Price **12s. 6d.** net.

A FRENCH-ENGLISH DICTIONARY FOR CHEMISTS
By AUSTIN M. PATTERSON, Ph.D.

Defines over 30,000 words and phrases and contains many irregular verb forms, and all common general words likely to appear in scientific literature, together with a valuable article on the conjugation of French verbs.

403 pages. Flexible binding.
Price **15s.** net.

CHAPMAN & HALL, LTD.,
11, HENRIETTA ST., LONDON, W.C. 2.

CHARCOAL
(WOOD)
From Stick to Powder of 150 Mesh.

Solvents for Lacquers, Varnishes, etc.
Rectified Oils of Tar
Pitch

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES London, December 28, 1923 No. 52

EDITORIAL

FARADAY discovered benzene in the year 1825, and the number of derivatives prepared from benzene is infinite. Ought we not to celebrate in some worthy manner the hundredth anniversary of this discovery? The occasion is noteworthy, and Faraday himself was a great man; this was not the greatest of his discoveries, he made many of supreme importance, but this one is the most significant in the domain of pure chemistry and can be identified with one particular date. The Faraday Society keeps his name before us and plays an important part in promoting knowledge of the frontiers of chemistry and physics, but we think some additional prominence should be given to the achievement of Faraday as a chemist, and that chemists might profitably consider in their leisure moments the most fitting means of celebrating the anniversary. Will our readers give the chemical world the benefit of their suggestions? It is not too early to consider the matter; if the thing is to be done, and done well, a good deal of organisation and publicity will be necessary.

* * *

It has been borne upon us of late that the pessimism regarding the status of chemistry in the public esteem is, perhaps, rather exaggerated. Before the war it was reasonably true to say that our wasted oil unprofitably burns, like hidden lamps in old sepulchral urns, but now we are inclined to think that the effect of this long-continued combustion is beginning to be perceptible—dimly, it may be, but still perceptible. Our readers will already have seen a headline in their favourite daily paper announcing the election of a new President of the Swiss Federation. But in the gloom and cold of these winter mornings such an announcement would hardly earn anything more than a casual glance. Yet it indicates a unique event, for it is the first time that a chemist has attained such a position of dignity. Monsieur Ernest Chuard, the new President, was professor of industrial chemistry at Lausanne when he was elected Federal Councillor in 1914, and since then he has been the head of the Finance Department. As far as we remember, one or two scientists have occupied high public positions; and we all know how journalists are favoured candidates for the Presidency across the Atlantic; but the news that a chemist has been chosen as the highest official in a modern and important State cannot fail to rejoice our hearts. We will not pause to consider how significant it is that the new President is, or was, concerned with industrial and not academic chemistry, as there should be no need of the distinction. We can safely point out that the Swiss are practical people, of great administrative ability, so that their choice of a chemist as their President implies that they, at least, do not consider that a knowledge of chemistry unfits a candidate for the highest office.

* * *

Hard upon the announcement recorded above come other cuttings from the daily Press that are of interest. At the Distribution Day dinner of the Salters' Company, Lord Askwith pointed out how industry was crying out for the help of science, but that science could do little unless industry also came to its help. He then showed how the Salters' Company was trying to bring science and industry together, and said that from the Salters' Institute great things would be expected. This is a spirit which should be far more common than it is. Memories of past inactivity, of neglected opportunities of applying science are far too abundant. We recorded in a previous issue the statement that somewhere in the '60's the Government of the day rejected experiments on the preservation of building stone because an expenditure of £150 would have been necessary; but the lack of permanence of certain artists' materials has been obvious, not only in Turner's pictures, but ever since the days of Leonardo da Vinci, whose experiments have, unfortunately, deprived us of more than one masterpiece owing to the lack of durability of his materials. Possibly it was necessary to wait for the present state of knowledge of oils, varnish and pigments before the question could be examined scientifically, but we are glad that, at last, the Royal Academy has appointed a committee, including both scientists and artists, to investigate the qualities of artists' materials and the various methods of cleaning old pictures. The composition of the committee warrants the hope that definite knowledge will be forthcoming to replace the empiricism that hitherto has characterised the choice of materials which serve to preserve the fleeting moment for the delight and instruction of future generations.

* * *

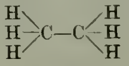
The Press, it will be realised, is now paying rather more attention to the doings of chemists, and it is all to the good that the public should be told that, for instance, the services of Dr. Alexander Scott and of Mr. A. Lucas are considered necessary to ensure the preservation of the objects found in the tomb of Tutankhamen. Dr. Scott has already done valuable work on the restoration and preservation of objects in the British Museum, and Mr. Lucas has, we understand, had similar experience during his directorate of the Egyptian Government Laboratory, Cairo; so it is to be hoped that as the "new" knowledge—too often "new" only in the sense of lacking application—spreads, we may be spared the sight of melancholy ruins displayed to our dismay in museum cases. Some attempts to record scientific events in the daily Press have been far from happy, however. A little time ago we were shown an illustration depicting a laboratory in which a chemist, supposed to be testing rubber, was pouring a fluid on a complete motor tyre, which he held easily at arm's length, and, more recently, the Press reports of one of our own Sectional meetings were not quite satisfactory. Prof. Ling recently gave a valuable review of the history of fermentation, particularly as applied to the brewing industry, at a meeting of the Nottingham Section. There was no lack of interesting points that could have been utilised in preparing a short account for public consumption, but apparently appreciation of these points was lacking, for a great London evening newspaper headed its note "Brewing in 1998 B.C.," which was repeated by a provincial paper, with the sub-heading, "What Ching-Young taught the Chinese." Our newspaper magnates are supposed to know exactly what the public wants, but we are indeed surprised to find that the history of science is so much appreciated. Yet we must be thankful for so much as this, for it is a beginning, and, for the present, that must suffice. It is well, however, to note that there is a slight period of three thousand odd years which remains to be bridged.

THE ACTIVATION OF HYDROGEN IN ORGANIC COMPOUNDS*

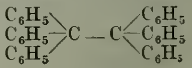
By EDITH HILDA USHERWOOD, Ph.D.

As a result of recent work on heavily substituted derivatives of ethane, everyone is now familiar with the idea that the strength of the carbon-carbon bond can be so diminished, that there is a progressive tendency towards dissociation in solution into two radicles, on passing, for instance, from ethane, through hexaphenylethane, which exists partly as triphenylmethyl in solution, to still more heavily substituted ethanes, for example tetraphenyldi-α-naphthylethane, which exists almost entirely as diphenyl-α-naphthylmethyl in solution (Gomberg and Schoepfle, *J. Amer. Chem. Soc.*, 1919, **41**, 1655. Gomberg, *Ber.*, 1904, **37**, 2049. Schmidlin, *Ber.*, 1908, **41**, 2471. Wieland, *Ber.*, 1909, **42**, 3029; and others).

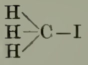
A similar phenomenon can also be noticed in the case of carbon-halogen bonds. Thus while this bond in methyl iodide is comparatively stable, it has been found by Walden (*Ber.*, 1902, **35**, 2029, 2031) that tertiary butyl iodide is ionised in sulphur dioxide solution:—



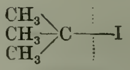
(stable)



(unstable)



(stable)



(unstable)

There is no doubt that a similar variation exists in the strength of the carbon-hydrogen bond, and although the weakening of the bond only proceeds in rare instances to such a degree that electrolytic dissociation occurs in solution, nevertheless the writer hopes to show that such variability as undoubtedly does occur is one of the main factors which govern the occurrence and reversibility of a great variety of apparently unrelated organic reactions, and, furthermore, is consequent upon certain well defined structural conditions. Before discussing the effect of structure, however, it is necessary to show that the presence of activated hydrogen in an organic molecule is indicated by a number of definite but independent criteria, which, however, point to an identical conclusion.

In the first place we may consider the group of criteria which arise from the relationship of this activation of hydrogen to dyad and triad tautomerism. The extensive researches which have centred around the class of phenomena which usually reveals itself in the fact that certain compounds afford ambiguous evidence of their structure have rendered it clear that the majority of such compounds contain the so-called triad system of the type :—

---

* Paper read before Section B (Chemistry) of the British Association on September 14, 1923.

$$(H)\ X-Y=Z \rightleftarrows X=Y-Z\ (H).$$

Since in the course of this reversible interchange the hydrogen atom, (H), must at some stage become detached from the terminal atoms, X and Z, of the system, it seems reasonable to suppose that tautomeric mobility of this kind will always necessarily be associated with the occurrence of hydrogen in that loosened or activated condition which is responsible for the wide range of organic reactions referred to in the preceding paragraph. An examination of the facts shows this to be the case, and hence we must include the usually accepted criteria for tautomeric mobility within the more extensive series of criteria for the activated condition.

Another widely applicable criterion of the existence of activated hydrogen is furnished by the formation of metallic derivatives. It will be evident that there is a remarkable parallelism between the property of forming metallic derivatives and capacity for tautomerism, and it is probably true to say that all substances which are capable of yielding metallic derivatives, and which, in addition, contain an appropriately situated double or triple bond, are actively tautomeric under suitable experimental conditions. The case of acetylene is an apparent exception, for it does not seem to have been previously suggested that acetylene is a tautomeric substance. However, the close formal and chemical analogy with hydrocyanic acid, which contains the dyad system, $(H).C\equiv N \rightleftarrows C=N(H)$ (Usherwood, *Trans. Chem. Soc.*, 1922, **121**, 1604) leads one to believe that acetylene might contain a similar mobile system, $(H).C \vdots CH \rightleftarrows C:CH(H)$, and it is of interest to note that Nef (*Annalen*, 1897, **298**, 332; 1899, **308**, 325) has obtained evidence of the existence of two series of halogen acetylenes corresponding with the two forms suggested for the parent hydrocarbon. If this analogy is sound, acetylene, although consisting mainly of $CH \vdots CH$, should be in equilibrium with a minute amount of $C:CH_2$, and a series of experiments designed to test the truth of this deduction are at present being carried out by the writer. In the meantime, therefore, it may be permissible to reserve the question as to whether acetylene is really an exception to the generalisation suggested at the commencement of this paragraph.

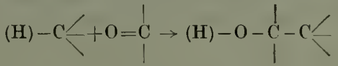
Capacity for alkylation is yet another important criterion of the presence of activated hydrogen. A cursory examination of the properties of typical tautomeric compounds shows that capacity for alkylation is intimately connected with the mobility of the system. For instance, the hydrogen atom of the carboxyl-group, which is sufficiently activated to be partly ionised in aqueous solution, is very readily replaced by an alkyl-group. Hydrocyanic acid, ethyl acetoacetate, ethyl β-aminocrotonate, ethyl glutaconate and indene, to mention only a few typical tautomeric substances, are all capable of alkylation, and indeed the parallelism of the two sets of phenomena is rendered obvious by the briefest survey of the evidence. The following table exemplifies this :—

System	Hydrogen tautomeric, X Hydrogen not tautomeric –		H replaceable by alkyl, X H not replaceable by alkyl –
Carboxyl group	X	..	X
Aci-nitro-group	X	..	X
Diazoaminobenzenes ..	X	..	X
α-γ-Diphenylamidines ..	X	..	X
Diphenylpropenes ..	—	..	—
Benzylidenebenzylamines	—	..	—
Glutaconic esters	X	..	X
Acylacetic esters	X	..	X
Indenes	X	..	X
Propylenes	—	..	—

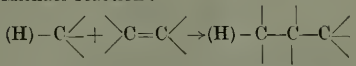
The power of a substance containing activated hydrogen to act as an addendum towards an unsaturated compound affords yet another means of recognising hydrogen in the activated condition, for the characteristic feature of additive reactions of this type is the separation of the activated hydrogen atom from the residue to which it was previously attached :—

$$(H)-X+A\overset{\cdot}{=}B \rightarrow (H)-A-B-X$$

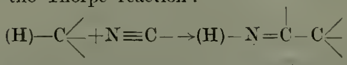
The aldol reaction :—



the Michael reaction :—



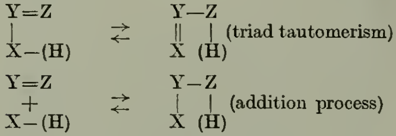
and the Thorpe reaction :—



are three well-known addition processes which belong to this type.

Now it is evident that only certain compounds contain a hydrogen atom which is sufficiently activated for the occurrence of additive reactions of this type. For instance, although acetaldehyde readily unites with itself to give aldol, and benzaldehyde easily combines with acetaldehyde, no one has hitherto succeeded in combining benzaldehyde with ethyl alcohol to give the compound $C_6H_5.CH(OH).CH_2.CH_2.OH$ or with ethane to give the compound $C_6H_5.CH(OH).CH_2.CH_3$. Similar remarks apply to the Thorpe and Michael reactions, and, in fact, an examination of the whole field shows that all these reactions follow upon certain well defined structural conditions which will be specified more definitely hereunder; in the meantime it is sufficient to point out that in the study of these reactions we have another means of obtaining information regarding the activation of any particular hydrogen atom.

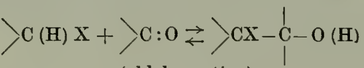
The correlation of this criterion for activated hydrogen with those previously discussed yields interesting results inasmuch as it leads to a number of striking and easily verifiable predictions. It has already been pointed out that activated hydrogen may migrate within the molecule thus giving rise to the phenomenon of triad tautomerism. Since, in order that this reaction should occur, it is necessary that the molecule should contain not only the residue with activated hydrogen but also an appropriately situated double bond, the change can be regarded as a kind of addition reaction, the residue containing activated hydrogen adding to the unsaturated residue, much as in the intermolecular additive processes now under discussion :—



$$\begin{array}{l} Y{=}Z \\ | \\ X{-}(H) \end{array} \rightleftarrows \begin{array}{l} Y{-}Z \\ \| \quad | \\ X \quad (H) \end{array} \text{ (triad tautomerism)}$$

$$\begin{array}{l} Y{=}Z \\ + \\ X{-}(H) \end{array} \rightleftarrows \begin{array}{l} Y{-}Z \\ | \quad | \\ X \quad (H) \end{array} \text{ (addition process)}$$

From this point of view, provided the addition processes can be shown to be reversible, a close formal similarity between the intra- and intermolecular types of change becomes immediately apparent, and we may, for instance, regard keto-enol tautomeric change as the intramolecular form of the aldol reaction :—



(aldol reaction),

(keto-enol tautomerism)

and so forth ; we may, in fact, institute a general comparison between reversible additive reactions involving activated hydrogen in the manner indicated and each of the principal kinds of triad tautomerism.

The analogy is not only a formal one. Taking the aldol reaction and keto-enol tautomeric change as an illustration, it will be shown below that both transformations are dependent on the condition of the hydrogen atom marked (H), activation in each case following upon identical or extremely similar structural conditions. Moreover, the writer has shown experimentally that the aldol reaction is reversible, and that aldols undergo fission into their factors under the conditions of their formation, the result being in each case a balanced action and an equilibrium which can be approached from either end, just as in keto-enol tautomerism. Thus both reactions are reversible and both are conditioned by the same type of activating influence (p. 1249) ; the essential difference between them is that the first is intermolecular and the second intramolecular. Hence we are led to regard the keto-enol change as an intramolecular aldol reaction, which takes place because the substance contains, side by side within the same molecule, both the residues, the carbonyl residue and the residue containing active hydrogen, by interaction of which an aldol reaction occurs. Essentially the same idea can more reasonably be expressed by saying that both the aldol and the keto-enol change are to be traced to a generally prevailing tendency towards the interaction of the two residues mentioned, and that this tendency operates whether the residues are in the same or in different molecules, hence arises the completeness of the analogy between the two processes.

The analogy between the Michael reaction and three-carbon tautomerism is equally complete, although no measurements of equilibria have as yet been made in any instance of three-carbon tautomerism.

Ingold and Powell (*Trans. Chem. Soc.*, 1921, **119**, 1976) first observed the reversibility of the Michael reaction, and Ingold and Perren (*ibid.*, 1922, **121**, 1414) subsequently showed that neither the direct nor the retrograde reaction depends on the conversion of one of the reacting esters into the sodio-derivative.

Hence it is suggested that the three-carbon change is merely an intramolecular Michael reaction, and that the occurrence and reversibility of changes of both types are due to a general tendency towards the interaction of an unsaturated residue with a residue containing active hydrogen, whether these residues occur within the same or in two different molecules.

From this point of view every triad system (H).X.Y=Z, may be regarded as consisting of two elementary parts, (H)–X and Y : Z, by inter-union of which tautomeric change takes place.

It may reasonably be enquired whether the development of this principle serves any purpose in the discovery and collation of organic chemical data. The answer is that it enables one to predict the hitherto unsuspected reversibility of well known additive processes, the aldol reaction for example, and the existence of new types of tautomerism, for instance, the various types of ring-chain tautomerism now under investigation in this laboratory (*compare* Ingold, Perren and Thorpe, *Trans. Chem. Soc.*, 1922, **121**, 1765).

A series of relationships have now been traced between several distinct, and, indeed, entirely dissimilar types of organic chemical reaction. The various manifestations of dyad and triad tautomerism, alkylation, the formation of metallo-derivatives, and additive reactions depending on the separation of hydrogen, have been brought into collation. Further, an explanation for the existence of these relationships has been offered in the suggestion that each of the phenomena dealt with depends ultimately on the same circumstance, namely, the occurrence of a hydrogen atom (or ion, perhaps) in a special condition which has been termed the activated condition. It is therefore of the utmost importance to enquire into the structural factors which give rise to that condition.

Two main classes of compounds containing an activated hydrogen atom have to be considered: (*a*) compounds in which hydrogen is attached to the electronegative atoms oxygen, sulphur or nitrogen; (*b*) compounds in which hydrogen is attached to carbon.

(*a*) Hydrogen attached to oxygen, sulphur or nitrogen is always activated, although naturally the degree of mobility depends on the configuration of the rest of the molecule. In cases in which nitrogen is attached to two hydrogen atoms, only one of these is in the activated condition, but if this becomes replaced by an alkyl group, then the other hydrogen atom becomes activated in turn.

(*b*) Hydrogen attached to carbon may or may not be mobile. It will be evident from the preceding survey that the loosening of a carbon-hydrogen bond runs closely parallel with the presence of the so-called negative groups—C : O,—CO_2Et, etc. That this is not an ordinary electrical effect is shown by the fact that elements such as chlorine and bromine, which, from their position in the periodic table and reactions in inorganic chemistry, are to be considered as strongly electronegative, when attached to carbon do not activate the adjacent hydrogen atom. For instance, there is a very marked difference between the activity of the hydrogen atom marked * in α-γ-dibromopropane and acetyl acetone: $Br{\cdot}CH_2{\cdot}CHH^*{\cdot}CH_2Br$. $CH_3{\cdot}CO{\cdot}CHH^*{\cdot}CO{\cdot}CH_3$. Apparently, then, the unsaturated condition represented by the double or triple bond is also necessary. But it alone is obviously insufficient, because ethylene, for example, which contains a double bond, does not contain an activated hydrogen atom. Neither is an oxygen (or nitrogen or sulphur) atom alone sufficient as may be seen by reference to the case of ethyl ether. Again, the presence of an electronegative element is not always necessary as the case of acetylene shows. It is evident, therefore, that the circumstances necessary and sufficient to secure activation are by no means simple; but it is possible, nevertheless, to embrace in two general formulæ the complete results of the preceding investigation:

(1) *The hydrogen atom represented by* (*H*) *in the group* $[H]{\cdot}C{\equiv}X$ *is activated no matter whether* X *is* C *or* N.

(2) *The hydrogen* (H) *in the group*

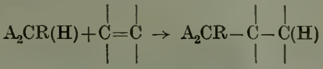
$$\left\{\begin{array}{l}(H)-C-X=Y\\(H)-C-X\equiv Y\end{array}\right.$$

is activated, no matter whether X *is* C *or* N, *provided* Y *is either the electronegative* O, N *or* S, *or is* C, *which itself is involved in the group*

$$\left\{\begin{array}{l}=C-X=Y\\=C-X\equiv Y\end{array}\right.$$

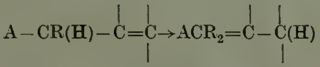
It will be noticed that these generalisations include both Lapworth's α-γ rule, and certain aspects of the more recently developed hypothesis of alternate polarities. There is no doubt that the material of this paper could with interest be interpreted in the light of the polarity hypothesis, but the writer's object, however, is not so much to institute proposals regarding the ultimate cause of organic chemical phenomena, as to effect a collation of data with the minimum of tacit hypothesis, to reduce tendency to undergo reactions to terms of molecular structure, and hence to seek the immediate rather than the ultimate cause of the facts which are on record.

It is to be borne in mind in interpreting the general formula given above, that the same degree of activation is not implied in all cases. Thus whilst two carbethoxyl or cyano-groups (A) are required so far to loosen the hydrogen atom in the system $A_2CR(H)$ that it can pass over to another molecule in the Michael reaction,



$$A_2CR(H)+\overset{|}{\underset{|}{C}}=\overset{|}{\underset{|}{C}} \rightarrow A_2CR-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}(H)$$

only one is necessary when the corresponding intramolecular process (three-carbon tautomerism) is in question:



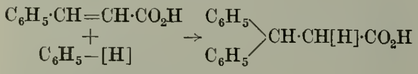
$$A-CR(H)-\overset{|}{C}=\overset{|}{\underset{|}{C}}\rightarrow ACR_2=\overset{|}{C}-\overset{|}{\underset{|}{C}}(H)$$

No doubt the compactness of the tautomeric system is responsible for the greater mobility of a hydrogen atom under given conditions of activation, and from this point of view it is interesting to note that keto-enol tautomeric change may be considered as an intramolecular aldol reaction in which the mobile hydrogen atom is activated by its own carbonyl group.

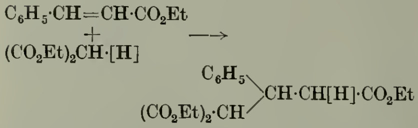
Note on the Activation of Hydrogen by the Benzene Nucleus

Whilst it is unnecessary to pass in review the more obvious application of the rules given on this page, it may not perhaps be inappropriate to call attention to the fact that the benzene nucleus, considered as a Kekulé individual, forms a special application of Rule 2. Therefore it is of interest to note that hydrogen attached to the benzene nucleus, although it satisfies only certain of the criteria which have been given for the existence of activated hydrogen, nevertheless participates in a number of reactions which plainly show that it is in an activated condition.

Thus the Michael and aldol reactions, which were taken as typical illustrations of additive processes depending on the activation of hydrogen, have their counterparts in which benzene C_6H_5-H becomes the addendum: the addition of benzene to cinnamic acid corresponds with that of malonic ester to cinnamic ester:

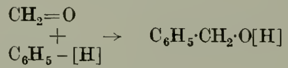


$$\begin{array}{c}\mathrm{C_6H_5{\cdot}CH{=}CH{\cdot}CO_2H}\\ +\\ \mathrm{C_6H_5{-}[H]}\end{array} \rightarrow \begin{array}{l}\mathrm{C_6H_5}\\ \mathrm{C_6H_5}\end{array}\!\!>\mathrm{CH{\cdot}CH[H]{\cdot}CO_2H}$$

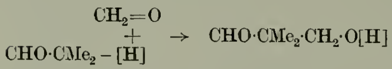


$$\begin{array}{c}\mathrm{C_6H_5{\cdot}CH{=}CH{\cdot}CO_2Et}\\ +\\ \mathrm{(CO_2Et)_2CH{\cdot}[H]}\end{array} \longrightarrow \begin{array}{r}\mathrm{C_6H_5}\\ \mathrm{(CO_2Et)_2{\cdot}CH}\end{array}\!\!>\mathrm{CH{\cdot}CH[H]{\cdot}CO_2Et}$$

and the addition of benzene to formaldehyde* with that of *iso*butaldehyde to the same substance:

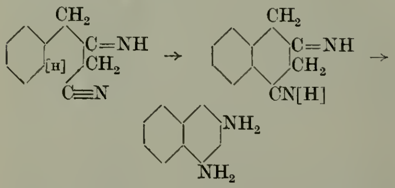


$$\begin{array}{c}\mathrm{CH_2{=}O}\\ +\\ \mathrm{C_6H_5-[H]}\end{array} \rightarrow \mathrm{C_6H_5{\cdot}CH_2{\cdot}O[H]}$$

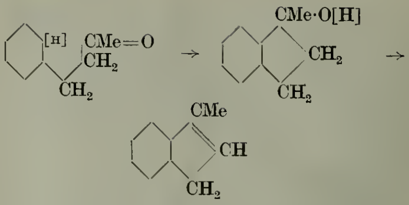


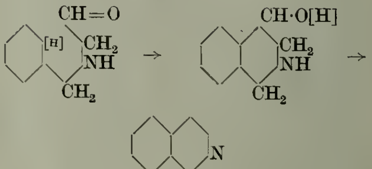
$$\begin{array}{c}\mathrm{CH_2{=}O}\\ +\\ \mathrm{CHO{\cdot}CMe_2-[H]}\end{array} \rightarrow \mathrm{CHO{\cdot}CMe_2{\cdot}CH_2{\cdot}O[H]}$$

Examples of what may be termed "intramolecular additive processes," reactions involving the migration of nuclear hydrogen to a double-bonded grouping situated in a side-chain attached to the same aromatic nucleus, fall into several classes according as the unsaturated residue is a cyano-group, a carbonyl-group, a nitroso-group, etc. Included within the first of these classes are certain of Thorpe's imino-reactions, for instance, the conversion of β-imino—γ-cyano-α-phenylpropane into 1 : 3 naphthylenediamine,

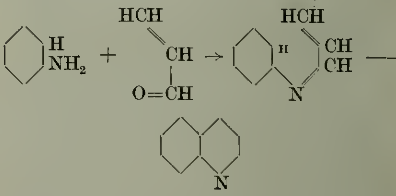


Instances of the class of reaction in which a carbonyl-group is involved are very numerous, illustrating the formation of many types of fused-ring nucleus. The formation of γ-methylindene from benzylacetone, and of *iso*quinoline from benzylaminoacetaldehyde may be taken as typical examples:

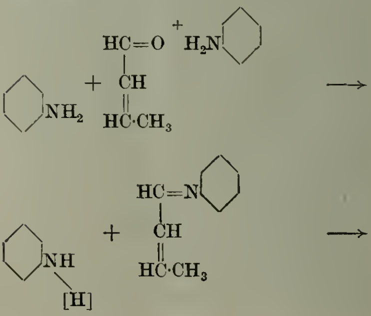




It is probable that Skraup's synthesis of quinoline derivatives also depends on the migration of aromatic hydrogen. The formation of quinoline itself, from aniline and acrolein, has been explained by supposing that the elimination of water from the aldehyde and base is followed by the direct removal of two hydrogen atoms by oxidation:

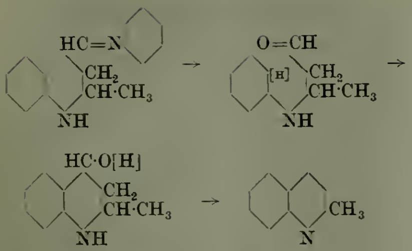


There is, however, clear evidence that the reaction cannot take this course, because on substituting crotonaldehyde for acrolein not γ-methylquinoline but α-methylquinoline is obtained. Attempts have been made to overcome this difficulty by supposing that two molecules of aniline take part in the reaction in the following manner (Blaise and Maire, *Compt. rend.*, 1902, **144**, 95):

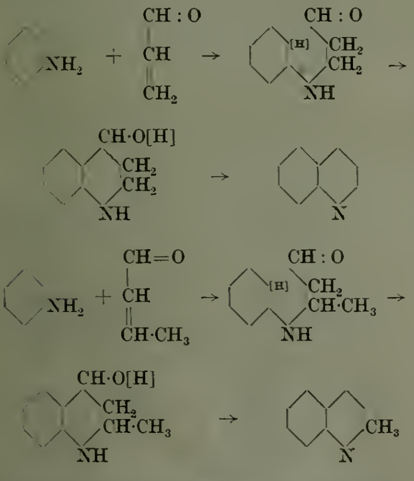


---

* The isolable product of this reaction is diphenylmethane, but as benzyl alcohol is known to be converted into diphenyl methane under the same experimental conditions, it is legitimate to assume that the reaction represented constitutes the first stage of the process. Indeed, there seems to be no plausible alternative.

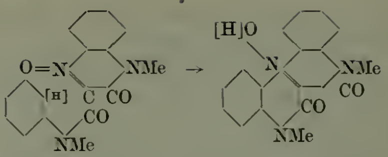


It is difficult, however, to see the necessity for these complicated assumptions, which involve condensation and hydrolysis under the same conditions. It would be simpler to assume that, both in this case and in the formation of quinoline itself, the reaction occurs between two molecules only, and that, in the presence of strong mineral acids, addition at the carbon-carbon double bond occurs in preference to the elimination of water between the amino- and aldehyde groups. Adopting this view the formation of quinoline and quinaldine are both very simply and uniformly interpreted as follows :—



the reactions furnishing additional examples of ring formation involving the passage of aromatic hydrogen on to the oxygen of a carbonyl group.

Some cases of analogous reactions involving the migration of nuclear hydrogen to the group N : O, either in the form of a nitroso-group, a nitro-group, or an *N*-oxido-group, have recently been described (Usherwood and Whiteley, *Trans. Chem. Soc.*, 1923, **123**, 1069), and may be sufficiently illustrated here by the following transformation of an *N*-oxido-compound.



Reactions such as these plainly show that apart from the possible influence of other groupings which the rules on p. 1249 define, the benzene ring, alone, has the power to bring about the activation of the hydrogen atoms attached to it ; but it has been thought right to append this note on the subject in view of the fact that the benzene nucleus constitutes a limiting and very special instance of the standard conditions which have been stated to lead to activation, an instance, which could not, therefore, have been assumed to fall into line with the general conclusions without an examination of the facts.

THE ACTION OF SODIUM SILICATE ON CONCRETE

In view of the great national importance of the question of the cost of upkeep of roads, much interest attaches to what is known as the silicate treatment for the hardening of concrete roads. This type of road will undoubtedly be employed very widely in the immediate future, following on the successful experience in the United States, and the progress made in the auxiliary treatment with silicate of soda is bound to play an important part in helping forward this development.

As is well known, the complex mixture known as silicate of soda, made by fusing together a good grade of sand with soda ash, is supplied in a considerable number of different grades or ratios, all of which are completely soluble in water, depending on the relative amounts of sand and soda used, the ratio figure being expressed as the number of molecules of silica (SiO_2) per 1 molecule of soda (Na_2O). The range varies from a low ratio product containing 1·6 molecules of silica to 1·0 molecules of soda to as high as 4·0 molecules silica to 1 of soda, the limits for complete solubility being about 21·5–42·1 per cent. SiO_2 and 5·25–26·95 per cent. Na_2O. Thus an example of a very commonly used silicate is " 2·0 molecules silica," in the form of a thick liquid of 100° Tw. at 20° C., the composition being 27·61 per cent. SiO_2, 14·19 per cent. Na_2O, and 58·20 per cent. water. All the various grades of silicate are generally sold in the liquid state, popularly known as " soluble glass " or " water glass," but may also be obtained as soluble powders and as "solid glass" in the lump form.

When a very dilute solution of silicate of soda, which must, however, be of the correct ratio to give the proper results, is applied to the surface of concrete, the solution penetrates to a depth depending on the condition and the original method of laying of the concrete. All concrete, no matter how carefully mixed, contains microscopic pores, but in practice considerable differences are shown in this respect. The result of the penetration is the formation of an intensely hard and dense outer skin or layer, which is much more resistant to abrasion and general wear and tear than ordinary untreated concrete, whilst being also more proof to water and oil and almost entirely dustless, without becoming slippery. The reactions that result when a very dilute solution, which must contain about 1 part of the commercial silicate of soda to 4 parts of water, is allowed to soak into concrete appears to consist chiefly of a combination of the soluble silicate of soda with free calcium hydrate always present in the concrete (being liberated in the setting of the cement) to give a hard, insoluble calcium silicate which completely fills up all the pores.

The firm of Brunner, Mond and Co., Ltd., which has devoted much attention to the whole question of silicate of soda during the past few years, has just issued an interesting booklet, "Concrete Roads" (which will be sent free of charge on application to the company at Northwich, Cheshire), containing a number of striking photographs of the surfaces of concrete roads, treated and untreated, after 6 months' heavy traffic. Treatment with silicate of soda has, it is stated, reduced the cost of upkeep of roads, so that the subject is obviously of considerable national importance.

Prof. Tammann, of Göttingen, has been elected the first honorary member of the Deutschen Gesellschaft für Metallkunde." Prof. G. F. Hüttig has been appointed professor of inorganic and analytical chemistry at Bonn.

The Académie des Sciences has allocated to M. Samsoen a subvention of 10,000 frs. from the Henry le Chatelier foundation for researches on the viscosity and dilatation of glass at high temperatures. The Montyon prize for mechanics has been awarded to M. H. Chipart, of St. Etienne, for his work on the gyroscopic theory of light, electro-magnetism and industrial electricity, and governors for steam engines.

FORTHCOMING EVENTS

Dec. 29 to Jan. 9. Scientific Novelties Exhibition, King's College, Strand, W.C. 2. Demonstrations and Experiments, 2—5 p.m., and 6—9 p.m.

Jan. 2. Institution of Electrical Engineers, *Wireless Section*, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "Some Experiments on the Screening of Radio Receiving Apparatus," by R. H. Barfield, M.Sc.

Jan. 3. Society of Chemical Industry, *Bristol Section*, Chemical Department, The University, Bristol, at 7.30 p.m. "The Chemical Technology of Canned Foods," by O. Jones.

Jan. 7. Institution of Electrical Engineers, Savoy Street, Victoria Embankment, W.C. 2, at 6 p.m. "Troubles with Domestic Electrical Appliances." Discussion opened by J. W. Beauchamp.

Jan. 7. Society of Chemical Industry, *London Section*, in the Rooms of the Chemical Society, Burlington House, W. 1, at 8 p.m. "The Estimation of Butyric Acid in Presence of Acetic Acid," by Dr. E. Fyleman; "The Estimation of Cadmium in Spelter and Zinc Ores," by C. E. Barrs.

Jan. 7. Institution of Rubber Industry, *London Section*, The Engineers' Club, Coventry Street, W. 1, at 8 p.m. "Consistency of Rubber and Rubber Compounds," by Dr. S. S. Pickles.

Jan. 8. Institution of Mechanical Engineers, *Swansea Section*, at Chamber of Commerce, Swansea, at 6 p.m. "Modern Developments in Steam Raising," by Sir J. H. R. Kemnal, F.R.S.

Jan. 8. Institute of Metals, *Birmingham Section*, Chamber of Commerce, New Street, Birmingham, at 7 p.m. "Nickel Brasses," by O. Smalley.

Jan. 8. Institute of Metals, *North-East Coast Section*, Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "The Action of Molten Brass on Nickel-Steel," by H. M. Duncan, B.Sc.

Jan. 10. Institute of Metals, *London Section*, Institute of Marine Engineers, 85—88, The Minories, Tower Hill, E. 1, at 8 p.m. "X-Rays and Metallurgy," by W. T. Griffiths, M.Sc.

Jan. 10. Institution of Mechanical Engineers, *Glasgow Section*, Royal Technical College, Glasgow, at 7.30 p.m. "Radiation and Atomic Structure," by Prof. J. Muir, D.Sc.

Jan. 11. Institute of Metals, *Sheffield Section*, The University, St. George's Square, Sheffield, at 7.30 p.m. "Influence of Casting Temperature on the Physical Properties of Metals," by F. H. Hurren. (Conjoint Meeting with the Institute of British Foundrymen).

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

NOTICE TO MEMBERS AND SUBSCRIBERS

The Annual Suscription falls due on January 1 next, and Members and Subscribers are reminded that no issues of the Journal for 1924 will be despatched to them until their subscriptions have been received at the Society's offices.

The formal applications for subscriptions will shortly be despatched to Members and Subscribers.

EXTRA COPIES OF ABSTRACTS

Members and subscribers may find it advantageous to have extra copies of the Abstracts section of the Journal printed on one side of the paper only, for filing purposes. The Society is prepared to supply these for the year 1924 in complete sets at a charge of £1 per set. Members and Subscribers who desire to avail themselves of this offer are requested to communicate with the General Secretary as soon as possible.

YORKSHIRE SECTION

On December 13, Mr. Mackay presided over a joint meeting with the Leeds Area Section of the Institute of Chemistry in Leeds, and Mr. Griffith Brewer, C.P.A., delivered an address on "Practice under the Modern Patent Law."

A patent is a bargain with the Crown, the monopoly being given in consideration of bringing a new thing into the country. In patents, therefore, claims must be stated very clearly. The granting of patents to importers was next dealt with and the International Convention explained. The most successful patents were the strings of patents representing progressive steps in building up a business; patents representing the spontaneous acts of individuals were more uncertain. The main portion of the address explained the Regulation introduced in 1919, whereby a patentee may have his patent endorsed "Licences of Right." The object was to secure that the invention is used to the greatest extent and the patentee is rewarded adequately as the Comptroller is empowered to intervene if a patentee refuses to grant a licence on reasonable terms. Although in the last four years 2000 patents had been brought within this Regulation, no compulsory licence of right had been granted against the will of the inventor. As a further inducement to the patentee to be reasonable the taxes payable on the patent endorsed in this way are reduced to half. In this way patentees would save £140,000 per annum in fees alone and in many cases offers to work the invention would result merely because of the declaration of the patentee that he would not be unreasonable. The suggestion was made that in the official announcement of the scale of fees a second column to the table be added showing the half fees payable in respect of patents so endorsed.

In the discussion Mr. Goodall said it was requisite to obtain expert advice before filing an application. Mr. Hodsman asked when a provisional patent for a chemical product had been obtained and in the nine months' interval by some alteration in the conditions an improvement had been effected, could the inventor add this when the complete specification was put in. In reply Mr. Brewer stated that it was first necessary to file a provisional specification describing the nature of the invention sufficiently to enable it to be identified. When an additional step had been gained, a cognate provisional patent should be taken out and the two united in one complete specification.

EDINBURGH AND EAST OF SCOTLAND SECTION

The third ordinary meeting was held jointly with the Edinburgh and East of Scotland Section of the Institute of Chemistry, in the Hall of the Pharmaceutical Society, Edinburgh, on December 11, Dr. A. Lauder presiding.

A lecture on "H.M. Factory, Gretna," was delivered by Mr. Allin Cottrell, who stated that the factory was designed as a propellant explosive factory with a capacity of 40,000 tons of cordite per annum. Previous to the war the volatile solvent acetone played a necessary part in gelatinising a mixture of nitroglycerin and guncotton which, with a small percentage of mineral jelly, composed the British service cordite. War conditions cut down supplies of acetone and it became necessary to develop a new cordite in which a mixture of ether and alcohol could be used to bring about gelatinisation. The Research Department of Woolwich was successful in doing this and evolved what came to be known as R.D.B. cordite. The scientific staff at Gretna had to develop the production on a gigantic scale of an explosive of which the details of the manufacture had just been worked out in the research laboratory.

The factory was divided into three separate areas for manufacturing purposes: Dornock, Ether, and Mossband. On the Dornock area were manufactured dynamite glycerin, sulphuric, nitric, and mixed acids, nitro-cotton and nitro-glycerin. The Ether area was given over to the manufacture of ether, and the

Mossband area was reserved for the production of the finished cordite and the recovery of the ether-alcohol solvent.

Mr. Cottrell described the rapid development of the factory from the time in 1915 when the site was surveyed to the time when the first consignment was dispatched for service at the front in August, 1916, and gave a clear account of the general organisation and running of the works. With the aid of numerous lantern slides the details were shown of the manufacture of cordite from start to finish, the different kinds of large scale plant, and the life and activities of the workers.

BIRMINGHAM AND MIDLAND SECTION

There was a large and representative attendance of chemists, members of the Birmingham and Midland Section of the Society of Chemical Industry, and the Institute of Chemistry, at the joint annual dinner at the Queen's Hotel, Birmingham, on December 15. Prof. G. T. Morgan, F.R.S., chairman of the local section of the Institute, presided. Dr. E. B. Maxted, chairman of the local section of the Society, was unable to be present owing to indisposition. Those present included :—Prof. W. P. Wynne, F.R.S., President of the Chemical Society, Dr. H. Levinstein, President of the British Association of Chemists, and Prof. Smith (Physics Department, University of Birmingham). Dr. E. F. Armstrong, President of the Society of Chemical Industry, wrote apologising for absence.

In proposing the toast, " The Society of Chemical Industry," Mr. H. B. Jacks (President of the Birmingham Metallurgical Society), pleaded for a closer alliance between science and industry, and pointed to the great and increasing part which chemistry was playing in the study of metallurgy. Mr. F. R. O'Shaughnessy, in responding, recalled the fact that a very large number of valuable scientific papers on various phases of metallurgical science had been read at the meetings in Birmingham of the Society of Chemical Industry ; chemistry was playing a greater part in industrial processes than ever before.

" The Institute of Chemistry " was proposed by Dr. Levinstein, who suggested that the democratic British Association of Chemists had rendered an admirable service in arousing the Institute from a prolonged slumber to visible signs of activity in unexpected directions. As a result, the Institute was stronger, more prosperous and more representative of chemists than ever before, and certainly it spoke with greater authority. He attributed this progress largely to the stimulus which had been given by other bodies, particularly the Association. Birmingham was to-day one of the great centres of chemistry, and he felt that the progress it had made was due very largely to the distinguished Professor of Chemistry at the Birmingham University, Dr. Morgan. It had been his business lately to try and acquire some knowledge of what had been done in the various chemical schools of this country in the last twenty or thirty years ; and one of the most striking developments had taken place in Birmingham, which a few years ago—he thought he could say so bluntly—was without a large and important school such as it had to-day. In the great enthusiasm for research, in the volume and quality of the research turned out, and in the number of students, Birmingham was not far behind—if at all behind—any chemical school in this country or elsewhere. The Institute, being a chartered Institute, had special functions to perform and was debarred from carrying out the kind of work which the British Association of Chemists was established to do—namely, to look after the more material interests of chemists, and to do what the Junior Medical Society did in the medical profession. He would welcome a much closer administrative connexion between the British Association of Chemists and the Institute, and it would be very desirable for the affairs of the two bodies to be administered from one office. He would also like to see more unity among the great societies of the chemical profession, and his hope was that it might be possible some day, by means of a combined subscription, for a man to obtain the whole of the literature of the several societies, as well as some closer association with them. Entrance fees and annual subscriptions to each body now made much too heavy a toll upon the financial resources of many young chemists.

The toast was honoured with enthusiasm, and Prof. Morgan, after a warm welcome to Prof. Wynne, likened, in humorous vein, the various chemical bodies to types of government by which mankind is afflicted. Dr. Levinstein had spoken of the lack of co-ordination, but there was a composition fee of £3 for those who subscribed to the publications of the Chemical Society and the Society of Chemical Industry. It would be seen that a good start had been made, and ultimately they might get a composition fee to include the Chemical Society, the Society of Chemical Industry, the Institute of Chemistry and the British Association of Chemists. He was glad reference had been made to the activities of the Institute, and he appreciated what had been said about the work of the Chemistry Department of the University. After all, he was merely the catalyst, the main body of the work being done by the gentlemen in the Department.

Mr. W. A. S. Calder, proposing the toast, " The Guests," referred to the value of university work from the view point of industry, and Dr. D. Stanley (President of the Midland Medical Association) responded.

HULL CHEMICAL AND ENGINEERING SOCIETY

On December 11, a meeting was held to hear an address on "Recent Advances in the Study of Corrosion," by Dr. J. N. Friend.

After emphasising the need for further research on the prevention of rust, Dr. Friend said it is generally recognised that when iron (or steel), air and water are brought into contact corrosion takes place. The iron, owing to the action of substances contained in itself, the air or the water, passes into solution in minute quantities, which are renewed as rapidly as they are thrown out of solution in the form of rust. Thus, for example, carbon dioxide being one of the most prevalent impurities, the action in most cases would appear to be that soluble ferrous bicarbonate and nascent hydrogen are formed, the nascent hydrogen combining with dissolved oxygen to form water. The ferrous bicarbonate is then hydrolysed to form ferrous hydroxide, which is oxidised to ferric hydroxide. The carbonic acid liberated through the hydrolysis of ferrous bicarbonate is free to attack more metal. And so the cycle continues.

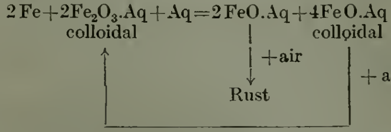
There are, however, many phenomena attendant upon the corrosion of iron which cannot be satisfactorily explained in the above manner, and it becomes evident that another supplementary theory is necessary. When water flows over a piece of iron in a tube the first effect of increasing the rate of flow is to enhance the corrosion of the metal. But a critical velocity is soon reached, namely, approximately one-tenth of a mile per hour, at which the corrosive effect attains a maximum, further increase in velocity resulting in a decrease of corrosion, until with a rate of flow of about four miles per hour, corrosion ceases. The metal under these conditions loses only very slightly in weight, probably in consequence of direct solvent action coupled with mechanical erosion.

This interesting phenomenon can neither be anticipated nor explained by any recognised theory of corrosion. It appears as if the moving water washes away from the surface of the metal something that is needful to induce corrosion. The author therefore suggests that on coming into contact with ordinary air and water, iron slowly dissolves in minute quantities, ultimately yielding ferrous hydroxide sol—that is, colloidal ferrous hydroxide. This sol oxidises in excess of air to ferric hydroxide sol (*i.e.*, colloidal ferric hydroxide, $Fe_2O_3.Aq$); in less favourable circumstances colloidal ferrosoferric hydroxide, $Fe_3O_4.Aq$, is produced.

This higher colloidal hydroxide now acts catalytically, accelerating the oxidation of the iron and simultaneously undergoing reduction to a lower colloidal hydroxide. It reoxidises as the air diffuses towards it, and so the cycle continues. Rust is formed when the colloidal hydroxide precipitates out or "flocculates."

In ordinary cases, therefore, corrosion may proceed in two ways simultaneously, namely: (i) By direct solution—a process rendered possible by the presence of dissolved electrolytes. (ii) By catalysis, this reaction being superimposed on the other, the colloidal iron hydroxide functioning in the presence of air as the active catalyst.

In acid solution the former of these reactions takes place almost exclusively. In neutral solution, the second reaction plays an important part. This colloidal theory may be represented briefly by the following scheme:—



$$2\,Fe + \underset{\text{colloidal}}{2Fe_2O_3.Aq} + Aq = 2\,FeO.Aq + \underset{\text{colloidal}}{4FeO.Aq}$$

This theory enables explanations to be offered for many interesting phenomena that are otherwise anomalous. Thus, for example, it is evident that any factor, whether mechanical, chemical, or electrical, that is capable of destroying the colloidal forms of iron hydroxide, will tend to retard corrosion. That is precisely what is found in practice to take place. Experiment shows that the relative precipitating powers of chromates, sulphates, and chlorides upon ferric hydroxide sol are as follows:—Chromates and dichromates, 100·0; sulphates, 67·0; chlorides and nitrates, 0·3. In other words, large quantities of nitrates and chlorides are required to precipitate the colloid, but only small quantities of chromates and dichromates, the sulphates lying intermediately. It is to be anticipated therefore that small quantities of chromates will inhibit corrosion. This is known to be so, and the addition of chromates to boiler feed waters and to paints destined for the preservation of iron has frequently been recommended.

Another interesting phenomenon is the behaviour of iron towards rays, which usually tend to accelerate oxidation processes. If the corrosion of iron is purely an ionic effect, exposure to radium rays should lead to enhanced corrosion. On the other hand, the rays tend to precipitate colloidal iron hydroxide, and will therefore, according to the colloidal theory, tend to retard corrosion. Experiment has shown that radium rays, springing from an exceedingly feeble source, exert a decided retarding action upon the corrosion of iron.

From France the death is announced of M. P. Pascal, Vice-President of the Société d'Electrochimie.

PERSONALIA

Mr. J. Barcroft has been elected Fullerian Professor of Physiology at the Royal Institution, in succession to Sir A. Keith ; and M. le Duc de Broglie, Dr. C. L. Guillaume and Profs. Debye, Einstein, Groth and von Laue have been elected honorary members of the Institution.

Mr. W. H. Hoffert, M.A., B.Sc., has been appointed research chemist to the Joint Research Committee of the National Benzole Association and the University of Leeds, in succession to Prof. E. C. Williams, now Ramsay professor of chemical engineering in the University of London. Mr. Hoffert will investigate the possibilities of increasing home supplies of motor spirit from coal.

Sir H. Harrison, Bart., founder of the chair of organic chemistry in the University of Liverpool, has contributed a further sum of £2500 towards the endowment of the chair.

Prof. A. Fowler, professor of astrophysics in the Imperial College of Science and Technology, has been appointed by the Royal Society to one of the Yarrow research fellowships which have been established in consequence of the gift of £400,000 by Sir A. Yarrow, to mark his " sense of the value of research to the community." Prof. Fowler has done valuable experimental work in spectroscopy, work in close association with the theoretical studies of Bohr which have led to such remarkable advance.

The title of Emeritus Professor has been conferred upon Prof. A. Smithells, F.R.S., by the University of Leeds in recognition of the value of his long service to the University.

Mr. R. Forsyth, M.Sc., has been appointed demonstrator in technological chemistry in the Faculty of Technology of Manchester University.

On the occasion of its fiftieth anniversary, the Dutch Union of " Gas-fabrikanten " has elected Dr. Charles Carpenter as an honorary member.

Dr. G. D. Rosengarten of Philadelphia, formerly a member of the board of directors of the American Chemical Society, has been elected to the newly organised executive committee.

* * *

From Germany the following deaths are announced :—J. Norden, founder of the Vereinigten Chemischen Fabriken Julius Norden and Co. ; Dr. A. Rüdiger, of the Chem. Pharm. A.-G. ; Dr. H. Pauli, of Frankfurt ; Dr. H. Teichmann, director of the Rutgerswerke A.-G.

From Italy the deaths are announced of Cav. L. Deponti, a well-known figure in the glucose and inorganic chemical industry, and of Dr. M. Ferko, well known in the soap industry.

NEWS AND NOTES

JAPAN

Patent Rights in Japan

During the recent disaster the whole of the registers and almost all the documents in the Japanese Patent Office were destroyed. To prevent detriment or inconvenience, the following regulations have been promulgated :—

Any right or interest given prior to September 1, 1923, and due to expire between September 1, 1923, and March 31, 1924, shall expire on the latter date, with the exception of rights and interests granted for a special period of duration, which shall remain valid during the specified period, provided that such period may be curtailed by the decision of an administrative office.

For any default of an application to be made to, or other steps to be taken with, the Minister of Agriculture and Commerce or the President of the Patent Office, between September 1 and December 30, 1923, in connexion with Patent, Utility, Model, Design, or Trade Mark, being caused by the earthquake, the aforesaid Minister or President may exempt the party concerned from the result of default, if he apply or take such steps not later than December 31, 1923, provided that, regarding the assertion of the right of priority grown out of the stipulation of a treaty, the aforesaid dates shall be March 30, 1924, and March 31, 1924, instead of December 30, 1923, and December 31, 1923, respectively.

Any person who, prior to September 1, 1923, applied for the prolongation of a patent right, and has not yet been granted any decision, shall present to the Patent Office not later than December 31, 1923, copies of the application and other relevant documents, together with a written statement declaring the date of the original application.

Any person who has obtained the registration of a Patent, Utility Model, Design, or Trade Mark shall apply for the recovery of registration prior to October 31, 1924, on which application his right of Patent, Utility Model, Design, or Trade Mark shall maintain the order in the original register.

It is important to note that a person not resident within the Empire of Japan cannot make an application to or take any other steps at the Patent Office except through a representative who is resident in the Empire.

FRANCE

Agricultural Research

A recent decree orders the creation of stations for research for the investigation and trial of scientific processes for the improvement and development of agricultural production. A number of central stations will be established for investigation of the various branches of agricultural science, whereas regional stations are to be established to carry out practical experiments and to test methods suitable for local application.

REVIEWS

The Chemistry of Rubber. By B. D. W. Luff, F.I.C. *Pp.* 232. *London: Ernest Benn, Ltd.*, 1923. *Price* 25*s.*

The chemistry of rubber is a subject that has received a good deal of attention in recent years. The rise and growth of the plantation rubber industry has synchronised with the development of research on the properties of rubber and the processes of vulcanisation. In the same period several textbooks or treatises have appeared covering the whole or part of the subject according to the individual outlook of the author. It is, however, curious to note that there is no recent book dealing specifically with the manufacturing side of the industry, the last to appear being that of Terry, published in 1907.

It is therefore somewhat disappointing to find that Mr. Luff has treated the manufacture of rubber goods in a very brief fashion, and consequently it cannot be said that the book relieves a pressing need. As research chemist to one of the largest manufacturing concerns in the industry, the author would appear well fitted for the task of filling a very conspicuous gap in the literature of the subject.

However, within the limits of his subject-matter the author has succeeded in writing a very excellent treatise in which he has embodied the essence of most of the research work that has been carried out on rubber during recent years. He possesses the gift of sorting out the subject-matter, selecting the essentials and putting them before the reader in a brief and lucid form. The historical introduction is well written. It is followed by chapters on rubber latex, wild rubber and plantation rubber, which contain a fairly correct description of the preparation of plantation sheet and crêpe rubber, which represent the bulk of the supply of raw material now reaching the manufacturer. The main body of the book deals with the physical and chemical properties of raw rubber, vulcanisation and the properties of the vulcanised rubber. They afford a very readable *résumé* of the experimental work so far accomplished, and although limitations of space have necessitated condensed accounts of the subject-matter, the author has nevertheless succeeded in presenting the essentials and has covered the whole ground without omitting any matter of first importance. There is a chapter on synthetic rubber amply commensurate with its technical importance; a chapter on the methods of manufacture, which, as already stated, is brief and contains no information which cannot be found in books written twenty years ago; and the final chapter deals with methods of analysis and epitomises the best methods in vogue.

The book is well illustrated with half-tone blocks, is well printed and light to handle. The editing has been most carefully done and the book does not contain a single misprint.

The book can be confidently recommended as supplying a brief yet readable account of our present knowledge of the chemistry of rubber, giving the essential details of the more important research work which has been carried out on the subject.

Henry P. Stevens

The Chemistry of Paints, Pigments and Varnishes. *By* J. Gauld Bearn, M.Sc., A.I.C. *Pp.* *x*+277. *London: Ernest Benn, Ltd.*, 1923. *Price* 30*s.*

Referring to the above it is stated that:—

> "This book, written from a strictly practical standpoint, supported by the author's twenty years' experience with various leading firms in the industry, covers all the most recent developments, and as such, as well as for the detailed description given of the chemistry and properties of all the various raw materials and finished products which they are called upon to handle, works managers, chemists, architects, engineers, and indeed, any persons either connected with the industry or whose calling necessitates the specification of materials for various protective uses, must find it invaluable.
>
> "A full description of the methods of analysing these raw materials and finished products have been included so that County Analysts and others dealing with this kind of work on behalf of County Councils, Local Authorities, and similar public bodies, may at last have a much-needed book of reference."

The author has endeavoured to attain his object in twenty-one chapters, each of which is devoted to a special section of the subject, in addition to which there are over forty illustrations, a bibliography and a ten-page appendix of mathematical and chemical data The general scheme of presentation is well conceived, but the detailed treatment is to some extent unsatisfactory. Typographical errors are far too numerous, and some are of such a character as to be a possible source of danger to anyone unfamiliar with the subject. Few of these should have escaped detection in proof-reading.

Apart from printers' errors, the work is open to criticism in certain sections, because of incomplete and out-of-date descriptions of both manufacturing processes and methods of chemical and physical examination. This is particularly seen in connexion with materials of which the author obviously has not first-hand knowledge, and has therefore been compelled to rely on the writings of others for much of the information he brings forward.

The ramifications of the paint and varnish industry are so numerous and varied, that it is almost impossible for one person to possess the knowledge necessary for the production of a treatise adequately covering all branches of the industry. There is marked reticence in the publication of details concerning manufacturing processes; the literature is not only scanty and incomplete, but often contradictory; and nice judgment and experience are required in determining the suitability of much of the published material for inclusion in a general work.

The author, at all times readable, is quite sound when he deals with his own subjects, and in places shows refreshing candour in his treatment of some of the perennial problems of general importance to the industry and the users of paint.

In its present form, the work has but a limited value, and in order to appeal to the large circle of readers for which it was intended, careful revision is necessary. The high price places the work outside the reach of many students of paint technology whose limited purses, in common with those of other students, do not appear to be considered in such matters. Students generally are complaining bitterly of the high prices asked for scientific and technical works to-day, and there would appear to be a good future for any publisher who will make the right move in this direction.

C. A. Klein

Oil Analysis. *By* A. H. Gill, S.B., Ph.D. *The Standard Short Hand-Book for Chemists and Engineers. Tenth edition, revised. Pp.* 223. *London: J. B. Lippincott.* 1923. *Price* 10*s.* 6*d.*

It will be noticed that the title of this book has been altered from "A Short Handbook of Oil Analysis" to "Oil Analysis," but the volume of the book has not very much increased. It has now reached its tenth edition, from which it would appear that it has been appreciated; the points of appreciation, however, are not very apparent.

Part I deals with physical and chemical tests, and includes two chapters devoted to petroleum products, one to animal and vegetable oils, and one to the examination of an unknown oil. In Part II the properties of some of the more commonly-occurring oils are considered, including petroleum products, vegetable and animal oils, waxes, and "waste fats." A voluminous appendix includes various tables of constants, notes on reagents, specifications for lard oil, petroleum products, compound oils, etc., and a description of Bailey and Baldsiefen's hexabromide method. This appendix appears to be the most valuable part of the book. The book is intended primarily for students, and descriptions of apparatus and methods of procedure receive considerable attention. These descriptions, however, are often of a somewhat telegraphic nature, which would matter less were the style adopted more lucid. As a typical example one may quote a sentence dealing with refractive index: "*This is of the same value as the determination of specific gravity; it has, however, the advantage that it is more rapid and uses only one or two drops of the oil.*" A perusal of the remarks under iodine value must necessarily leave the student with his mind in confusion. Minute details of various investigators' methods are given, but no guiding principle to enable the student to adopt the most accurate way of working himself.

This edition of the book is stated to bring the contents thoroughly up-to-date, but a lack of reference to modern literature is nevertheless one of its most striking features.

It may be noted that butter, which is treated under pages headed "Waste Fats," is described as "*adulterated with oleomargarine, renovated butter and cocoanut oil. The first may be detected by testing for cotton-seed or sesame oil either by the color tests or by the index of refraction.*" It is questionable whether such enlightenment may not be worse for the student than no knowledge of the subject at all. The author states that this work is intended to serve as an introduction to the standard textbooks, but the thought strikes one that the student would be better advised to tackle the standard works straightaway than get ideas into his head which a later perusal would certainly eradicate.

The work, however, may have found a use in supplying headings to be amplified in lectures, and this may account for the publication of ten editions.

E. R. Bolton

Lehrbuch der Keramik. *By* Dr. H. Hecht *Pp.* 336. *Berlin and Vienna: Urban and Schwarzenberg*, 1923.

As Dr. Hecht is not only a tutor associated with the Technical School at Charlottenburg, but is the successor to Professor Seger (the inventor of the well known "Seger cones") in the Chemisches Laboratorium für Tonindustrie, in Berlin, any book written by him will naturally attract the attention of all interested in the great clayworking industries. Yet a careful reading of this newly published volume is very disappointing because the author has not written a new and really modern book incorporating useful information not published in other works on ceramics, but has followed very closely an old and well known book. This new volume can, perhaps, best be described as a précis of Kerl's "Handbuch der gesammten Tonindustrie" (the last edition of which, published in 1906, was revised by Cramer and Hecht), to which have been added various items of information which have aroused interest during the seventeen years since the last edition of Kerl's book was published. Not only is there a very close resemblance in the text (the recipes for bodies and glazes being the same in many instances), but many of the old wood-cut illustrations from Kerl's book appear in the new volume. It is true that the present volume is only about one-third of the size of the older one, but few readers will consider this an advantage, as a considerable amount of valuable information and most of the references to the original papers are omitted.

In this new volume, attention is chiefly paid to what may be termed "practical" information as distinct from that of a more purely scientific character, although a considerable amount of space is devoted to the latter. The various raw materials are described first, then the methods employed for converting them into various kinds of wares. The drying and firing of the ware occupies only 20 pages, methods of decoration 13 pages and supervision and control 11 pages. Each class of ware is then briefly described together with the methods employed in its manufacture, more than half the volume being occupied in this way; one page is devoted to an alphabetical list of papers and books almost wholly by German authors, the only English one mentioned being Solon's "History of Old English Porcelain."

The only reference to the colloidal nature of clays which the reviewer has been able to find is in a single paragraph on page 11. The cause of plasticity is summed up in ten lines and then in an erroneous manner!

The three formulæ proposed by Groth, Zulkowsky and Purkall, respectively, for the chemical constitution of clay are all mentioned, but no attempt is made to show which, if any, is correct, or to point out the objections to them.

The sections on refractory materials and on the electro-osmosis process are brief but good, though they are descriptive rather than critical; Wernicke's book on the latter subject has been freely used, with, of course, due acknowledgment, but without criticism. The summary of Berdel's work on semi-refractory sanitary ware and the description of the technique of Chinese porcelains are among the best of the newer parts of the work. The index, like those in most German books, is very poor.

Notwithstanding these defects, the volume as a whole forms a handy summary of the chief methods employed in the pottery and allied industries in Germany, and so may be useful to those who do not wish to study the larger, or more specialised works by other writers. If it is really up-to-date, it shows quite clearly that the Germans are in no way ahead of the British in regard to the technique of clayworking, and they are distinctly behind in some respects—particularly in lustre ware, fine earthenware, chemical stoneware and sanitary ware with a fireclay basis.

Apparently the only matter in which they are still in advance of the average English practice is that they burn some of their fire-bricks at a much higher temperature than is customary here. A. B. Searle

REPORTS

Report on the Economic Situation of the Netherlands East Indies to June, 1923. *By* H. A. N. Bluett, *Commercial Agent, Batavia. Department of Overseas Trade. Pp.* 112. *H.M. Stationery Office,* 1923. *Price* 3*s.*

The optimism expressed in the last report (*cf. J.*, 1922, 458) has been justified and during the period now under review the trade depression has passed away. Export trade is now almost booming, and a greater demand for imports has followed.

The year 1922-3 proved favourable to most crops and prospects for the current year are good. Oil palm cultivation is increasing, and though the output is still small the industry appears to be well established.

The administration of the State-owned mines and collieries has recently been re-organised. The production of crude petroleum in 1921 was 2,361,509 t. Several oil-fields are as yet undeveloped. The bulk of the coal obtained in the islands comes from the State-owned mines, which produced 765,431 t. in 1922, about 180,000 t. less than in 1921. Gold, silver, and tin are also mined. Sodium iodide is obtained from springs; in 1922 25 t. of iodine and 46 t. of copper iodide were exported.

Manufacturing industries have made progress during the last two years, principally in the preparation for the market of various naturally occurring substances. The plentiful water-power is a great asset, and extension of industry will no doubt lead to further hydro-electric developments; at present only 60,000 to 70,000 h.p. has been developed out of the 5,500,000 h.p. available.

The principal exports in 1922 included sugar, 1,400,000 t; rubber, 31,659 t.; cinchona bark, 6616 t.; quinine, 125 t.; tin, 15,546 t.; indigo, 17 t. For importers the period was not favourable, mainly owing to local conditions. There is now, however, a good demand for, among other things, chemicals, cement, tin-plate, copper and brass. There is a considerable market for some lines of chemicals and manures of British origin, and there is reason for hoping that in the future Great Britain may be the principal source of heavy chemicals.

Report on Financial, Industrial and Commercial Conditions in Canada, to June, 1923. *By* F. W. Field, *H.M. Trade Commissioner, Toronto.* Together with a Supplementary Report on Western Canada *by* L. B. Beale, *H.M. Trade Commissioner of Vancouver. Department of Overseas Trade. Pp.* 96. *London: H.M. Stationery Office.* 1923. *Price* 2*s.* 6*d.*

During the year under review conditions have rapidly approached normal (*cf. Chemistry and Industry*, 1923, 57). There were some financial failures, but these can only be considered as a result of the inflation and over-extension that took place in the years just after the war. The industrial situation was improved by elimination of weak concerns, by consolidation, and by reduction of overhead charges. Preference for British goods in the tariff was extended, the preference amounting to 10 per cent. of the duty where it amounted to more than 15 per cent. of the value of the article. A system of bounties is in force by which producers of certain goods, *e.g.*, copper bars and rods, hemp, petroleum, imported duty-free are assisted.

The chief points of interest in the mineral industry were the gold production, which exceeded 1,000,000 oz., and the shortage of coal. The total value of minerals produced in 1922 was $183,029,595. For the first time for many years large quantities of coal were imported from Great Britain, viz., 639,000 tons of bituminous and 178,000 t. of anthracite. Imports from the U.S.A. were 13·4 mill. t. divided in about the same proportion. The question of coal supply seems to be becoming more and more serious. The threat of an embargo by the U.S.A. on exports of anthracite to Canada looms large, and imports from Great Britain may be considerably increased, especially if producers in this country interest themselves in the market. The production of petroleum was 178,567 barrels, valued at $609,679, imports being valued at $36·8 mill.; the Ontario and Brunswick fields are not likely to give an increased yield. Prospecting has been carried out mainly in Western Provinces.

There has been rapid industrial progress in Canada in the past few years. Of the 42,046 factories in existence in 1920, 79 per cent. were in Eastern Canada. The largest number was engaged in the production of non-ferrous metals and their products, chemicals and allied products coming next. Progress continues to be made by hydro-electric developments, and the industry is stable. In 1922 the total installation reached 3,000,000 h.-p.

Total imports into Canada in 1922 amounted to $762·3 mill.; and exports to $898·2. Imports from the U.S.A. are considerably more than those from the United Kingdom, though the position of the latter improved slightly last year. There is a strong demand for British goods, but emphasis is laid on the necessity for considerable study of the special conditions obtaining in Canada.

Prof. C. W. Parmelee, who has been connected with the ceramic engineering department of the University of Illinois since 1916, has recently been made head of the department, having acted in that capacity during the past year.

COMPANY NEWS

PAN DE AZUCAR NITRATE CO., LTD.

At the twenty-second annual meeting the chairman said that after paying the proposed dividend of 15 per cent., less tax, there remained £30,491 to be carried forward. The nitrate industry had shown a marked improvement in the spring of 1923, when demand developed strongly. In the year ended June 30 last, the total world's consumption of nitrate amounted to 2,160,000 tons as against 1,545,000 t. in the previous year, and world stocks at June 30, 1923, were 1,249,000 t., as compared with 1,873,000 t. at the same date in 1922, which showed that consumption had increased satisfactorily during the year and stocks were down to about normal. Sales of nitrate in the current year were going on well, and it was expected that the total would reach 2,300,000 t. The Producers' Association had already sold about 1,409,000 t. for shipment July 1, 1923, to June 30, 1924, and further sales for a considerable quantity were expected to be made. The average sale price secured was about 9s. 3¾d. per Spanish quintal, from which 4d. per quintal had to be paid as compensation to the pool. The outlook seemed encouraging, especially in view of the increasing demand from the United States.

LANGDALE'S CHEMICAL MANURE CO., LTD.

The profit for the year ended September 30, 1923, was £5532, to which should be added reserves transferred to general profit and loss account amounting to £10,170. After deducting the debit balance brought forward from last year the credit balance is £110, which is to be carried forward. Competition by Continental makers has been most severe during the past year, and the quantity of foreign superphosphate sold to the United Kingdom below the cost of manufacture to the home producer has considerably increased. Sales of sulphuric acid and manures were larger than during last year.

EASTERN CHEMICAL CO., LTD.

The result of the year's working up to March 31, 1923, after further writing down of stocks to replacement cost, and allowing for the usual depreciation, was a loss of £10,503. The serious trade depression in India, combined with keen local competition and the dumping of German chemical products at prices much below world values and the cost of manufacture in India, reduced both output and gross profits. The directors are investigating the manufacture of additional products for which there is a demand in India, and they have also started to merchant imported goods not manufactured in India. The directors are unable to recommend the payment of any dividend for the period of the accounts.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The heavy chemical market maintains a steady tone, both home trade and export continuing to take tolerably satisfactory quantities. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£7 10s. per ton, spot, delivery. General export demand good particularly from the Continent.
Bleaching Powder	Spot £11 5s. d/d.; Contract £10 5s. d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain).
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d.—6d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17–£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19–£20 10s. per ton according to quantity, f.o.b. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£17—£17 10s. per ton according to quantity, 1-cwt. wooden kegs included, f.o.b. London.

RUBBER CHEMICALS

Prices in this section are unchanged.

Antimony Sulphide—	
Golden	6d.—1s. 5d. per lb.
Crimson	1s. 3d.—1s. 8d. per lb.
Arsenic Sulphide, Yellow	2s. per lb.
Cadmium Sulphide	4s. 9d. per lb.
Carbon Bisulphide	£25—£29 per ton according to quantity.
Carbon Black	6½d. per lb. for shipment c.i.f. London. Spot supplies from 7d. per lb. according to quantity.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Fair demand, but much competition.
Lead Hyposulphite	8d. per lb.
Lithopone	£23 per ton. Fair demand.
Mineral Rubber "Rubpron"	£16—£18 per ton.
Sulphur	£10 10s.—£12 10s. per ton, according to quality; demand fair.
Thiocarbanilide	2s. 8d. per lb.
Zinc Sulphide	7½d. per lb.

WOOD DISTILLATION PRODUCTS

With the exception of acetates of lime and lead the demand for wood distillation products keeps below normal. Naphthas are an unsettled market.

Acetate of Lime—	
Brown	£14—£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. „ „ 24° Tw.
Red Liquor	10d.-1s. „ „ 14/15° Tw.
Wood Creosote	2s. 7d. „ „ Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Competition being met with.
Solvent	6s. per gall. 40% O.P. Fair demand.
Wood Tar	£4 15s.—£6 per ton according to grade. Demand not very brisk.
Brown Sugar of Lead	£42—£43 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. per lb. Weaker, with limited demand.
Crude 60's	2s. 9d.—3s. per gall. Little business passing.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Firm, with good demand.
Pale 95%	1s. 10d.—2s. per gall.
Dark	1s. 7d.—1s. 10d. per gall. A little inquiry for forward delivery.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—	
Strained	9d.—10d. per gall. Better demand. Little material available.
Unstrained	8d.—9d. per gall. Quiet.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 4d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 6½d.—1s. 8d. per gall. ex works in tank wagons.
Toluole—90%	1s. 3d.—1s. 4d. per gall.
Pure	1s. 9d.—1s. 10d. per gall.
Xylol	2s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.—11d. per gall. Not much business.
Middle Oil Heavy Standard Specification	8½d.—9½d. per gall. according to grade and district. Market very firm.
Naphtha—	
Crude	8½d.—8¾d. per gall.
Solvent 90/160	1s. 1d.—1s. 2d. per gall. Market weak.
Solvent 90/190	1s. 1d.—1s. 3d. per gall. Business quiet.
Naphthalene Crude—	
Drained Creosote Salts	£5—£8 per ton. Demand increasing. Market scarce.
Whizzed or hot pressed	£9—£11 per ton. Quiet.
Naphthalene—	
Crystals	£19 per ton.
Flaked	£19 per ton.
Pitch, medium soft	100s.—105s. per ton. Rather more inquiry, but little business passing.
Pyridine—90/140	22s.—23s. per gall. Demand easier.
Heavy	8s. per gall. Price nominal.

INTERMEDIATES AND DYES

The slight improvement in dyestuffs business has been maintained, but orders are still only for small quantities.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 7d. lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 6½d.-1s. 7d. per lb. Much better demand.
Acid Sulphanilic	1s. 1d. lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	9d.—10d. per lb. naked at works.
Aniline Salts	9½d.—10d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 7d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 29/31° C.	5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Market quieter.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Market quieter.
Dichloraniline	2s. 2d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. 0d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 6d. per lb. d/d. Drums extra.
Dinitrobenzene	10d. per lb. naked at works.
Dinitrochlorbenzol	£83 per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d.—1s. 3d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 6d. per lb. d/d.
Nitrobenzene	5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. lb. 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 8d. lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	4s.—4s. 6d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The demand is falling off as the end of the year approaches, but further appreciation in prices may be expected after the holiday period.

Acid, Acetic 80% B.P.	£48 10s. per ton.
Acid, Acetyl Salicylic	3s. 7d.—3s. 9d. per lb. Price hardening. Some makers asking 4s. In very steady demand.
Acid, Benzoic	B.P. quality almost unobtainable. Commercial quality offered forward at 2s. 3d. per lb. for cwt. lots. Makers fully sold ahead.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton.
Acid, Camphoric	17s.—19s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5%, for ton lots. Dearer.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. per lb. for 28 lb. lots.
Acid, Salicylic	2s. 6d.—2s. 7d. per lb. Very firm market. Makers hard pressed to meet demand.
Acid, Tannic	3s. 3d. per lb. for B.P. quality. Very firm.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Firmer. More inquiry for forward delivery.
Amidol	9s. per lb. d/d.
Acetanilide	Advanced to 3s. 6d. per lb. on a short market.
Amidopyrin	13s. 6d. per lb. Demand negligible.
Ammon. Benzoate	4s. 3d.—5s. per lb. for English make. Cheaper than other benzoates.
Ammon. Carbonate B.P.	£27 15s. per ton.

Atropine Sulphate	12s. 6d. per oz. for English make. Dull market.
Barbitone	18s. per lb. Without much inquiry.
Benzonaphthol	6s. per lb. Very much firmer.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	£29—£31 per ton, carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9d.—10d. Remain very firm. Continental prices advancing.
Sodium	9½d.—10d.
Ammonium	10d.—11d.
Calcium Lactate	2s. 9d. per lb. for best English make. A better market.
Chloral Hydrate	4s. 3d. per lb. Position very firm and active.
Chloroform	2s. per lb. for cwt. lots. More active.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	Spot supplies very scarce. Present value 14s. per lb.
Hexamine	4s. 6d. per lb. for foreign makes. Manufacture in England has been discontinued since formaldehyde was removed from the dutiable list.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£72 10s. per ton, less 2½%.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol	A.B.R. recryst. B.P. 62s. 6d. per lb.
Mercurials	Firm and likely to advance.
Red oxide	4s. 11d.—5s. 1d. per lb.
Corrosive sublimate	3s. 8d.—3s. 10d. ,,
White precip.	4s. 6d.—4s. 8d. ,,
Calomel	4s. 1d.—4s. 3d. ,,
Methyl Salicylate	3s. per lb. for carboys. Brisk market. Slightly advanced.
Methyl Sulphonal	22s. per lb.
Methylene di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 7d. per lb.
Phenacetin	7s. 6d. per lb. Steady market. English makers fully employed. Foreign supplies shorter.
Phenazone	8s. 9d. per lb. In short supply.
Phenolphthalein	8s. 6d. per lb. Very firm.
Potass. Bitartrate—99/100% (Cream of Tartar)	90s. per cwt., less 2½%. Market firmer.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Permanganate	9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d.—5s. 9d. per lb. Neglected.
Salol	4s. per lb. In more plentiful supply.
Silver proteinate	10s. 6d. per lb. Quiet.
Sod. Benzoate	3s. 6d. per lb. Scarce.
Sod. Citrate, B.P.C., 1923	1s. 5d.—1s. 9d. per lb., according to quantity. Very firm, in common with other citrates.
Sod. Hyposulphite—Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.—85s. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 11d. per lb., and Crystal at 3s. per lb. Firm and very active. Supplies still scarce.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£25—£26 per ton, according to quantity, 1-cwt. drums included f.o.b. London.
Sulphonal	17s. 6d. per lb.
Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	11s. 6d. per lb.
Aubepine	14s. ,, ,,
Amyl Acetate	3s. ,, ,,
Amyl Butyrate	7s. 3d. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (M.P. 21/22° C.)	3s. 9d. ,, ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate	4s. ,, ,,
Cinnamic Aldehyde Natural	22s. 6d. ,, ,,
Coumarin	20s. ,, ,,
Citronellol	19s. 6d. ,, ,,
Citral	10s. ,, ,,
Ethyl Cinnamate	10s. ,, ,,
Ethyl Phthalate	3s. 9d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	37s. 6d. ,, ,,
Geraniol	6s to 13s. 6d. per lb.
Heliotropine	8s. 6d. per lb.
Iso Eugenol	15s. 9d. per lb.
Linalol ex Bois de Rose	20s. ,, ,,

Linalyl Acetate ..	.. 20s. ,, ,,
Methyl Anthranilate	.. 8s. 6d. ,, ,,
Methyl Benzoate	.. 6s. ,, ,,
Musk Ketone ..	.. 52s. 6d. ,, ,,
Musk Xylol ..	.. 19s. ,, ,,
Nerolin	.. 4s. ,, ,,
Phenyl Ethyl Acetate	.. 10s. ,, ,,
Phenyl Ethyl Alcohol	.. 16s. ,, ,,
Rhodinol.. ..	.. 60s. ,, ,,
Safrol	.. 1s. 10d. ,, ,,
Terpineol ..	.. 3s. ,, ,,
Vanillin	.. 25s. 3d.—26s. 6d. per lb. Firm with steady demand. Raw materials dearer.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A... ..	.. 14s. 6d. per lb.
Anise Oil.. ..	.. 1s. 11d. ,, ,,
Bergamot Oil ..	.. 13s. 3d. ,, ,, spot.
Bourbon Geranium Oil..	37s. ,, ,,
Camphor Oil ..	.. 75s. per cwt.
Cananga Oil, Java	.. 9s. 6d. per lb.
Cinnamon Oil, Leaf	.. 5¾d. per oz.
Cassia Oil 80/85%	.. 11s. 6d. per lb.
Citronella Oil—	
Java 85/90%	.. 4s. 9d. ,, ,,
Ceylon.. ..	.. Very little on offer.
Clove Oil.. ..	.. 10s. 6d. per lb.
Eucalyptus Oil 70/75%..	2s. 6d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil ..	.. 2s. 10d. per lb. Higher prices expected.
Lemongrass Oil ..	.. 2¾d. per oz.
Orange Oil, Sweet	.. 11s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 34s. per oz.
Anatolian ..	.. 26s. per oz.
Palma Rosa Oil	.. 24s. 6d. per lb.
Peppermint Oil—	
English ..	.. 70s. per lb. Market very unsteady.
Wayne County	.. 15s. 6d. per lb. Market very unsteady.
Japanese ..	.. 12s. 6d. per lb. Market very unsteady.
Petitgrain Oil ..	.. 9s. 6d. per lb. Dearer.

TRADE NOTES

British Empire Exhibition: Mineral and Metallurgical Exhibits

In connexion with the British Empire Exhibition, the Imperial Mineral Resources Bureau, 2, Queen Anne's Gate Buildings, Dartmouth Street, London, S.W. 1, has in preparation a descriptive handbook and guide in which reference will be made to mineral and metallurgical exhibits. Under each mineral or metal references will be made in this guide to those firms who are known to be showing raw materials and semi-manufactured products of the mineral and metal industries.

It is requested that all firms proposing to exhibit materials likely to come within the scope of the handbook will communicate to the Bureau the exact nature of their exhibit so that it may be considered for the purpose of cross-reference. Where possible an analysis and the source of the material should be stated.

The Bureau cannot accept any responsibility for any omissions from the handbook, but will endeavour to include references to all firms exhibiting crude mineral and semi-manufactured products, if information about the exhibits is received at the Bureau not later than March, 1924.

French Company News

The production of coal by the Cie. des Mines de Béthune during the year ended June 30, 1923, was 1,655,326 metric tons. Development of the mines continues, and electrification is being extended. At the company's factories the policy of providing for the utilisation of all the by-products continues to be applied. Tests of the Claude process have given results which have induced the company to decide to manufacture synthetic ammonia by this process. Tar distillation plant to treat 40 tons per day is now working and purifying apparatus has been attached to the coke-ovens. The generating station, which now develops 32,000 kilowatts., is shortly to be enlarged to develop 48,000 kw.

On December 7 the sequestrated factory of Weiler ter Meer at Tourcoing was sold to the Flament Co., for 432,000 francs, whereas the sequestrated factory belonging to the International Galalith Gesellschaft Hoff und Co., at Gennevilliers, was sold for 1,061,667 fr. to Monsieur Boussac, of Paris.

Cement Industry in Esthonia

The first cement factory was built in Esthonia in 1870, and owing to the high quality of the product, Esthonian cement soon became known in the Russian and foreign markets. The output was considerable, especially in years preceding the war, a favourable factor being that all the necessary raw materials are available on the spot, and located near the sea coast and main railway lines. After the revolution and the declaration of Esthonian independence the cement works were quickly rebuilt and work resumed. Esthonian oil-shale was found to be a most satisfactory substitute for imported coal, and the oil-shale ash is now used successfully as an ingredient of the cement, the quality of which remains unaffected. Exports of cement totalled 20,519 tons in 1922, as compared with 7480 t. in 1921 and 5412 t. in 1920. The purchasing power of Russia is still very insignificant, and the principal buyers of late years have been Latvia, Finland, Lithuania, the Scandinavian States, Belgium and France, the cement being used in the two last-named countries for reconstruction work.
